NAME	limit, ulimit, unlimit – set or get limitations on the system resources available to the current shell and its descendents
SYNOPSIS	<code>/usr/bin/ulimit [-f] [blocks]</code>
sh	<code>ulimit [- [HS] [a cdfnstv]]</code> <code>ulimit [- [HS] [c d f n s t v]] limit</code>
csh	<code>limit [-h] [resource [limit]]</code> <code>unlimit [-h] [resource]</code>
ksh	<code>ulimit [-HSacdfnstv] [limit]</code>
/usr/bin/ulimit	The <code>ulimit</code> utility sets or reports the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.
sh	The Bourne shell built-in function, <code>ulimit</code> , prints or sets hard or soft resource limits. These limits are described in <code>getrlimit(2)</code> . If <i>limit</i> is not present, <code>ulimit</code> prints the specified limits. Any number of limits may be printed at one time. The <code>-a</code> option prints all limits. If <i>limit</i> is present, <code>ulimit</code> sets the specified limit to <i>limit</i> . The string <code>unlimited</code> requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see <code>su(1M)</code> . The <code>-H</code> option specifies a hard limit. The <code>-S</code> option specifies a soft limit. If neither option is specified, <code>ulimit</code> will set both limits and print the soft limit. The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set. <code>-c</code> maximum core file size (in 512-byte blocks) <code>-d</code> maximum size of data segment or heap (in kbytes) <code>-f</code> maximum file size (in 512-byte blocks) <code>-n</code> maximum file descriptor plus 1 <code>-s</code> maximum size of stack segment (in kbytes) <code>-t</code> maximum CPU time (in seconds) <code>-v</code> maximum size of virtual memory (in kbytes)

csh The C-shell built-in function, `limit`, limits the consumption by the current process or any process it spawns, each not to exceed *limit* on the specified *resource*. If *limit* is omitted, print the current limit; if *resource* is omitted, display all limits. (Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` command).

`-h` Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

resource is one of:

<code>cputime</code>	Maximum CPU seconds per process.
<code>filesize</code>	Largest single file allowed. Limited to the size of the filesystem (see <code>df(1M)</code>).
<code>datasize</code>	The maximum size of a process's heap in kilobytes.
<code>stacksize</code>	Maximum stack size for the process (see <code>swap(1M)</code>).
<code>coredumpsize</code>	Maximum size of a core dump (file). This is limited to the size of the filesystem.
<code>descriptors</code>	Maximum number of file descriptors (run <code>sysdef ()</code>).
<code>memorysize</code>	Maximum size of virtual memory.

limit is a number, with an optional scaling factor, as follows:

<code>nh</code>	Hours (for <code>cputime</code>).
<code>nk</code>	<i>n</i> kilobytes. This is the default for all but <code>cputime</code> .
<code>nm</code>	<i>n</i> megabytes or minutes (for <code>cputime</code>).
<code>mm:ss</code>	Minutes and seconds (for <code>cputime</code>).

`unlimit` removes a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the `limit` command for the list of resource names.

`-h` Remove corresponding hard limits. Only the privileged user may do this.

ksh The Korn shell built-in function, `ulimit`, sets or displays a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value `unlimited`. The `-H` and `-S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the `-H` or `-S` options is

limit(1)

specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case, the soft limit is printed unless *-H* is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- a Lists all of the current resource limits.
- c The number of 512-byte blocks on the size of core dumps.
- d The number of K-bytes on the size of the data area.
- f The number of 512-byte blocks on files written by child processes (files of any size may be read).
- n The number of file descriptors plus 1.
- s The number of K-bytes on the size of the stack area.
- t The number of seconds (CPU time) to be used by each process.
- v The number of K-bytes for virtual memory.

If no option is given, *-f* is assumed.

OPTIONS The following option is supported by `ulimit`:

- f Set (or report, if no *blocks* operand is present), the file size limit in blocks. The *-f* option is also the default case.

OPERANDS The following operand is supported by `ulimit`:

blocks The number of 512-byte blocks to use as the new file size limit.

/usr/bin/ulimit **EXAMPLE 1** Limiting the stack size

To limit the stack size to 512 kilobytes:

```
example% ulimit -s 512
example% ulimit -a
time(seconds)          unlimited
file(blocks)           100
data(kbytes)           523256
stack(kbytes)          512
coredump(blocks)       200
nofiles(descriptors)   64
memory(kbytes)         unlimited
```

sh/ksh **EXAMPLE 2** Limiting the number of file descriptors

To limit the number of file descriptors to 12:

```
example$ ulimit -n 12
example$ ulimit -a
time(seconds)          unlimited
file(blocks)           41943
data(kbytes)           523256
stack(kbytes)          8192
```

EXAMPLE 2 Limiting the number of file descriptors (Continued)

```
coredump(blocks)      200
nofiles(descriptors)  12
vmemory(kbytes)       unlimited
```

cs **EXAMPLE 3** Limiting the core dump file size

To limit the size of a core dump file size to 0 kilobytes:

```
example% limit coredumpsize 0
example% limit
cputime                unlimited
filesize               unlimited
datasize               523256 kbytes
stacksize              8192 kbytes
coredumpsize           0 kbytes
descriptors            64
memorysize             unlimited
```

EXAMPLE 4 Removing the limitation for core file size

To remove the above limitation for the core file size:

```
example% unlimit coredumpsize
example% limit
cputime                unlimited
filesize               unlimited
datasize               523256 kbytes
stacksize              8192 kbytes
coredumpsize           unlimited
descriptors            64
memorysize             unlimited
```

ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `ulimit`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned by `ulimit`:

- 0 Successful completion.
- >0 A request for a higher limit was rejected or an error occurred.

NAME	line – read one line				
SYNOPSIS	line				
DESCRIPTION	The <code>line</code> utility copies one line (up to and including a new-line) from the standard input and writes it on the standard output. It returns an exit status of 1 on EOF and always prints at least a new-line. It is often used within shell files to read from the user's terminal.				
EXIT STATUS	Exit status is: 0 Successful completion >0 End-of-file on input.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

lint(1B)

NAME	lint – C program verifier
SYNOPSIS	<code>/usr/ucb/lint</code> [<i>options</i>]
DESCRIPTION	<code>/usr/ucb/lint</code> is the interface to the BSD Compatibility Package C program verifier. It is a script that looks for the link <code>/usr/ccs/bin/ucblint</code> to the C program verifier. <code>/usr/ccs/bin/ucblint</code> is available only with the SPROcc package, whose default location is <code>/opt/SUNWspro</code> . <code>/usr/ucb/lint</code> is identical to <code>/usr/ccs/bin/ucblint</code> , except that BSD headers are used and BSD libraries are linked <i>before</i> base libraries. The <code>/opt/SUNWspro/man/man1/lint.1</code> man page is available only with the SPROcc package.
OPTIONS	<code>/usr/ucb/lint</code> accepts the same options as <code>/usr/ccs/bin/ucblint</code> , with the following exceptions: -I <i>dir</i> Search <i>dir</i> for included files whose names do not begin with a slash (/) prior to searching the usual directories. The directories for multiple -I options are searched in the order specified. The preprocessor first searches for #include files in the directory containing <i>sourcefile</i> , and then in directories named with -I options (if any), then <code>/usr/ucbinclude</code> , and finally, in <code>/usr/include</code> . -L <i>dir</i> Add <i>dir</i> to the list of directories searched for libraries by <code>/usr/ccs/bin/ucblint</code> . This option is passed to <code>/usr/ccs/bin/ld</code> . Directories specified with this option are searched before <code>/usr/ucblib</code> and <code>/usr/lib</code> . -Y <i>P, dir</i> Change the default directory used for finding libraries.
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.
FILES	<code>/usr/lint/bin/ld</code> link editor <code>/usr/lib/libc</code> C library <code>/usr/ucbinclude</code> BSD Compatibility directory for header files <code>/usr/ucblib</code> BSD Compatibility directory for libraries <code>/usr/ucblib/libucb</code> BSD Compatibility C library <code>/usr/lib/libsocket</code> library containing socket routines <code>/usr/lib/libnsl</code> library containing network functions <code>/usr/lib/libelf</code> library containing routines to process ELF object files <code>/usr/lib/libaio</code> library containing asynchronous I/O routines
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

list_devices(1)

NAME	list_devices – list allocatable devices
SYNOPSIS	list_devices [-s] [-U <i>uid</i>] -l [<i>device</i>] list_devices [-s] [-U <i>uid</i>] -n [<i>device</i>] list_devices [-s] [-U <i>uid</i>] -u [<i>device</i>]
DESCRIPTION	<p>The <code>list_devices</code> utility lists the allocatable devices in the system according to specified qualifications.</p> <p>The <i>device</i> and all device special files associated with the device are listed. The device argument is optional and, if it is not present, all relevant devices are listed.</p>
OPTIONS	<p>The following options are supported:</p> <p>-l [<i>device</i>] Lists the pathname(s) of the device special files associated with the device that are allocatable to the current process. If <i>device</i> is given, lists only the files associated with the specified device.</p> <p>-n [<i>device</i>] Lists the pathname(s) of device special files associated with the device that are allocatable to the current process but are not currently allocated. If <i>device</i> is given, lists only the files associated with that device.</p> <p>-s Silent. Suppresses any diagnostic output.</p> <p>-u [<i>device</i>] Lists the pathname(s) of device special files, associated with the device that are allocated to the owner of the current process. If <i>device</i> is given, list only the files associated with that device.</p> <p>-U <i>uid</i> Uses the user ID <i>uid</i> instead of the real user ID of the current process when performing the <code>list_devices</code> operation. Only a user with the <code>solaris.devices.revoke</code> authorization can use this option.</p>
EXIT STATUS	<p>The following exit values are returned:</p> <p>non—zero An error occurred.</p>
FILES	<p>/etc/security/device_allocate</p> <p>/etc/security/device_maps</p> <p>/etc/security/dev/*</p> <p>/usr/security/lib/*</p>
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

list_devices(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO allocate(1), deallocate(1), bsmconv(1M), dminfo(1M), device_allocate(4), device_maps(4), attributes(5)

NOTES The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

listusers(1)

NAME	listusers – list user login information
SYNOPSIS	listusers [-g <i>groups</i>] [-l <i>logins</i>]
DESCRIPTION	Executed without any options, this command lists all user logins sorted by login. The output shows the login ID and the account field value from the system's password database as specified by <code>/etc/nsswitch.conf</code> .
OPTIONS	The following options are supported: -g <i>groups</i> Lists all user logins belonging to <i>group</i> , sorted by login. Multiple groups can be specified as a comma-separated list. -l <i>logins</i> Lists the user login or logins specified by <i>logins</i> , sorted by login. Multiple logins can be specified as a comma-separated list.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `nsswitch.conf(4)`, `attributes(5)`

NOTES A user login is one that has a UID of 100 or greater.

The `-l` and `-g` options can be combined. User logins will only be listed once, even if they belong to more than one of the selected groups.

NAME llc2_autoconfig – generate LLC2 configuration files

SYNOPSIS `/usr/lib/llc2/llc2_autoconfig [-f]`

DESCRIPTION The llc2_autoconfig utility is used to generate LLC2 configuration files (`/etc/llc2/default/llc2.*`). If there is no configuration file in `/etc/llc2_default/`, it detects all the available interfaces in the system and generates corresponding default configuration files.

If there are existing configuration files in `/etc/llc2_default/`, it will check if those interfaces defined in the files still exist. If they do not exist in the system, it will set `llc2_on` in those files to 0. After this, it will detect if there are new interfaces in the system. If there are, it will generate configuration files for them.

OPTIONS The following option is supported:

`-f` Erases all configuration files in `/etc/llc2/default/`. Then detects all the available interfaces in the system and generates corresponding default configuration files. Use this option with caution.

FILES `/etc/llc2/default/llc2.*` LLC2 configuration files

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWllc

SEE ALSO `llc2_config(1)`, `llc2(4)`, `attributes(5)`, `llc2(7D)`

llc2_config(1)

NAME	llc2_config – configure LLC2 interface parameters																
SYNOPSIS	<code>/usr/lib/llc2/llc2_config [-P -U -d -q -i <i>ppa</i> -r <i>ppa</i>]</code>																
DESCRIPTION	The <code>llc2_config</code> utility is used to start/stop the LLC2 subsystem and to configure LLC2 interface parameters.																
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-d</code> Turns on debug mode. Extra debugging information will be printed out.<code>-i <i>ppa</i></code> Initializes the corresponding interface using the file <code>/etc/llc2/default/llc2.<i>ppa</i></code>.<code>-P</code> Reads in all <code>/etc/llc2/default/llc2.*</code> configuration files, opens those devices defined in the files, and sets up the streams needed for LLC2 to use those devices. Before doing this, <code>llc2_config -q</code> will not show anything.<code>-q</code> Queries the LLC2 subsystem. Information similar to the following example will be printed out for all PPAs (Physical Point of Attachment) available under the LLC2 module: <table><thead><tr><th>PPA</th><th>State</th><th>ID</th><th>MACAddr</th><th>Type</th><th>MaxSDU</th><th>MinSDU</th><th>Mode</th></tr></thead><tbody><tr><td>0</td><td>up</td><td>0000</td><td>0800208a217e</td><td>ethernet</td><td>1500</td><td>0</td><td>3</td></tr></tbody></table> <p>The fields displayed are described below:</p> <ul style="list-style-type: none">PPA The relative logical position of the interface.State The state of the interface:<ul style="list-style-type: none"><i>up</i> The interface is initialized and operational.<i>down</i> The interface was "discovered" by the LLC2 driver, has passed its bootup diagnostics, and is awaiting initialization.<i>bad</i> The interface is known to the LLC2 driver, but failed one or more of the integrity checks performed at boot time. This might include detecting Interrupt Request and shared memory conflicts or failures detected during the execution of the level 0 diagnostics.ID The interface ID.MACAddr The MAC address currently in effect for the interface.Type The MAC type. Current types supported include:	PPA	State	ID	MACAddr	Type	MaxSDU	MinSDU	Mode	0	up	0000	0800208a217e	ethernet	1500	0	3
PPA	State	ID	MACAddr	Type	MaxSDU	MinSDU	Mode										
0	up	0000	0800208a217e	ethernet	1500	0	3										

llc2_config(1)

csma/cd 10 Megabit Ethernet
 ethernet Ethernet type device
 tkn-ring 4/16 Megabit Token Ring
 fddi 100 Megabit Fiber Distributed Data Interface

MaxSDU The Maximum Service Data Unit size transmitted on this interface.

Mode The Service Modes supported by this interface. This field consists of the bitwise logical-ORing of the supported modes, also defined in /usr/include/sys/dlpi.h.

-r *ppa* Uninitializes the corresponding interface. By using this option, and then using the -i option, the parameters associated with an interface can be changed.

-U Destroys all streams used by the LLC2 subsystem. This is the reverse of the -P option. After this is executed, llc2_config -q will not show anything.

FILES /etc/llc2/default/llc2.* LLC2 configuration files

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

llc2_stats(1)

NAME	llc2_stats – LLC2 Station, SAP, and Connection Statistics						
SYNOPSIS	llc2_stats <i>ppa</i> [-r] [-s <i>sap</i>] [-c <i>connection</i>]						
DESCRIPTION	The llc2_stats command is used to retrieve statistical information from the Host-based Logical Link Control Class 2 component of the LLC2 Driver. Statistics are kept for the station, SAP (Service Access Point), and connection components.						
OPTIONS	The following options are supported: <table><tr><td>-c <i>connection</i></td><td>Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.</td></tr><tr><td>-r</td><td>Resets the specified counters to zero after reading them. This option is only valid if the <i>root</i> user is executing the command.</td></tr><tr><td>-s <i>sap</i></td><td>Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS sap, 240 (0xf0) would be entered as: -s f0.</td></tr></table>	-c <i>connection</i>	Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.	-r	Resets the specified counters to zero after reading them. This option is only valid if the <i>root</i> user is executing the command.	-s <i>sap</i>	Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS sap, 240 (0xf0) would be entered as: -s f0.
-c <i>connection</i>	Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.						
-r	Resets the specified counters to zero after reading them. This option is only valid if the <i>root</i> user is executing the command.						
-s <i>sap</i>	Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS sap, 240 (0xf0) would be entered as: -s f0.						
OPERANDS	The following operand is supported: <table><tr><td><i>ppa</i></td><td>The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.</td></tr></table>	<i>ppa</i>	The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.				
<i>ppa</i>	The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.						
EXAMPLES	EXAMPLE 1 Station Statistics The following command will display the station statistics for PPA 4. After the example, a brief description of each field is presented. <pre>example% /usr/lib/llc2/llc2_stats 4</pre> <pre>Station values received: ppa = 0x00000004 clearFlag = 0x00 # of saps (hex) = 0x0002 saps (hex) = 02 aa state = 0x01 nullSapXidCmdRcvd = 0x00000000 nullSapXidRspSent = 0x00000000 nullSapTestCmdRcvd = 0x00000000 nullSapTestRspSent = 0x00000000 outOfState = 0x00000000 allocFail = 0x00000000 protocolError = 0x00000000</pre> The fields are described as follows: <table><tr><td><i>ppa</i></td><td>The logical number used to address the adapter.</td></tr><tr><td><i>clearFlag</i></td><td>This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).</td></tr></table>	<i>ppa</i>	The logical number used to address the adapter.	<i>clearFlag</i>	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).		
<i>ppa</i>	The logical number used to address the adapter.						
<i>clearFlag</i>	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).						

EXAMPLE 1 Station Statistics *(Continued)*

# of saps	The number of SAPs currently bound on this station.
saps	The array of the station's Service Access Point (SAP) logical interface values between the LLC and its adjacent layers.
state	A number indicating the current state of the station component (0 = down, 1 = up).
nullSapXidCmdRcvd	The number of XID command Protocol Data Units (PDUs) received for the NULL SAP address (sap = 0x00).
nullSapXidRspSent	The number of XID response PDUs sent in response to XID command PDUs received for the null SAP address.
nullSapTestCmdRcvd	The number of TEST command PDUs received for the null SAP address.
nullSapTestRspSent	The number of TEST response PDUs sent in response to TEST command PDUs received for the null SAP address.
outOfState	The number of events received in an invalid state.
allocFail	The number of buffer allocation failures.
protocolError	The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.

EXAMPLE 2 SAP Statistics

In the above display, there are two active SAPs, 0x02 and 0xaa. The following is an example of a command for retrieving the statistics for SAP 02 and a brief explanation of each field presented.

```
example% /usr/lib/llc2/llc2_stats 4 -s 02
```

```
Sap values received:
ppa          = 0x00000004  clearFlag = 0x00
sap          = 0x02
state       = 0x01
# of cons (hex) = 0x0000000a
connections (hex) = 0000 0001 0002 0003 0004 0005 0006 0007 0008 0009
xidCmdSent   = 0x00000000
xidCmdRcvd   = 0x00000000
xidRspSent   = 0x00000000
xidRspRcvd   = 0x00000000
testCmdSent  = 0x00000000
testCmdRcvd  = 0x00000000
testRspSent  = 0x00000000
```

llc2_stats(1)

EXAMPLE 2 SAP Statistics (Continued)

```
testRspRcvd      = 0x00000000
uiSent           = 0x00000000
uiRcvd          = 0x00000000
outOfState      = 0x00000000
allocFail       = 0x00000000
protocolError    = 0x00000000
```

The fields are described as follows:

ppa	The logical number used to address the adapter.
clearFlag	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).
sap	The specified Service Access Point (SAP) logical interface value for the station.
state	A number indicating the current state of the SAP component (0 = inactive, 1 = active).
# of cons	The number of active connections on this SAP.
connections	The array of active connection indexes.
xidCmdSent	The number of XID command PDUs sent (Source SAP = this sap).
xidCmdRcvd	The number of XID command PDUs received (Destination SAP = this sap).
xidRspSent	The number of XID response PDUs sent (Source SAP = this sap).
xidRspRcvd	The number of XID response PDUs received (Source SAP = this sap).
testCmdSent	The number of TEST command PDUs sent (Source SAP = this sap).
testCmdRcvd	The number of TEST command PDUs received (Destination SAP = this sap).
testRspSent	The number of TEST response PDUs sent (Source SAP = this sap).
testRspRcvd	The number of TEST response PDUs received (Source SAP = this sap).
uiSent	The number of Unnumbered Information Frames sent.
uiRcvd	The number of Unnumbered Information Frames received.

EXAMPLE 2 SAP Statistics (Continued)

outOfState	The number of events received in an invalid state.
allocFail	The number of buffer allocation failures.
protocolError	The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.

EXAMPLE 3 Connection Statistics

Ten established connections are associated with this SAP. To retrieve the statistics for connection 1, enter the following command:

```
example% /usr/lib/llc2/llc2_stats 4 -s 2 -c 1
Connection values received:
ppa          = 0x0004  clearFlag    = 0x00
sap          = 0x02    con          = 0x0001  sid          = 0x0201
stateOldest = 0x00    stateOlder  = 0x00    stateOld    = 0x01
state        = 0x08
dl_nodeaddr = 0x0080d84008c2          dl_sap      = 0x04
flag        = 0x50    dataFlag    = 0x00    timerOn     = 0x18

sendAckTimerExp = 0x0000
```

ppa	The logical number used to address the adapter.
clearFlag	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).
sap	The specified Service Access Point (SAP) logical interface value for the station.
con	The specified connection index value for the SAP.
stateOldest	A number representing the state of the connection component prior to stateOlder.

llc2_stats(1)

EXAMPLE 3 Connection Statistics (Continued)

stateOlder	A number representing the state of the connection component prior to stateOld.
stateOld	A number representing the state of the connection component prior to state.
state	A number representing the most current state of the connection component. See Table 1.
sid	The Station Identifier composed of the SAP (upper byte) and connection index (lower byte).
dl_nodeaddr	The Data Link Node Address. This is the destination node's MAC address.
dl_sap	The destination node's SAP.
flag	The connection component processing flag. See Table 3.
dataFlag	A number representing the status of the data units from received I-frame PDUs (0 = not discarded, 1 = discarded, 2 = busy state entered with REJ PDU outstanding).
timerOn	A number representing the timer activity flag, with each bit representing an active timer for this connection. See Table 2 for timer definitions.
vs	The sequence number of the next I-frame PDU to send.
vr	The expected sequence number of the next I-frame PDU to be received.
nrRcvd	The sequence number plus 1 of the last sent I-frame PDU acknowledged by the remote node.
k	The transmit window size.
retryCount	The retryCount is incremented whenever a timer expiration occurs. These timers protect outbound frames.
numToBeAcked	The number of outbound I-frames awaiting acknowledgement.
numToResend	The number of outbound I-frames to be retransmitted.
macOutSave	No longer used.
macOutDump	No longer used.
iSent	The number of I-frames sent.

EXAMPLE 3 Connection Statistics (Continued)

iRcvd	The number of I-frames received.
frmrSent	The number of Frame Reject PDUs (FRMR) sent.
frmrRcvd	The number of Frame Reject PDUs (FRMR) received.
rrSent	The number of Receiver Ready PDUs (RR) sent.
rrRcvd	The number of Receiver Ready PDUs (RR) received.
rnrSent	The number of Receiver Not Ready PDUs (RNR) sent.
rnrRcvd	The number of Receiver Not Ready PDUs (RNR) received.
rejSent	The number of Reject PDUs (REJ) sent.
rejRcvd	The number of Reject PDUs (REJ) received.
sabmeSent	The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) sent.
sabmeRcvd	The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) received.
uaSent	The number of Unnumbered Acknowledgment PDUs (UA) sent.
uaRcvd	The number of Unnumbered Acknowledgment PDUs (UA) received.
discSent	The number of Disconnect PDUs (DISC) sent.
outOfState	The number of events received in an invalid state.
allocFail	The number of buffer allocation failures.
protocolError	The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.
localBusy	The number of times this component was in local busy state and could not accept I-frames.
remoteBusy	The number of times the remote connection component was busy and could not accept I-frames.
maxRetryFail	The number of failures that occurred because maxRetry was reached.
ackTimerExp	The number of expirations of the Acknowledgement timer.
pollTimerExp	The number of expirations of the Poll timer.

llc2_stats(1)

EXAMPLE 3 Connection Statistics (Continued)

rejTimerExp	The number of expirations of the Reject timer.
remBusyTimerExp	The number of expirations of the Remote Busy timer.
inactTimerExp	The number of expirations of the Inactivity timer.
sendAckTimerExp	The number of expirations of the Send Acknowledgement timer.

ln(1)

NAME	ln – make hard or symbolic links to files
SYNOPSIS	<pre>/usr/bin/ln [-fns] source_file [target] /usr/bin/ln [-fns] source_file... target /usr/xpg4/bin/ln [-fs] source_file [target] /usr/xpg4/bin/ln [-fs] source_file... target</pre>
DESCRIPTION	<p>In the first synopsis form, the <code>ln</code> utility creates a new directory entry (link) for the file specified by <i>source_file</i>, at the destination path specified by <i>target</i>. If <i>target</i> is not specified, the link is made in the current directory. This first synopsis form is assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error will result.</p> <p>In the second synopsis form, the <code>ln</code> utility creates a new directory entry for each file specified by a <i>source_file</i> operand, at a destination path in the existing directory named by <i>target</i>.</p> <p>The <code>ln</code> utility may be used to create both hard links and symbolic links. A hard link is a pointer to a file and is indistinguishable from the original directory entry. Any changes to a file are effective independent of the name used to reference the file. Hard links may not span file systems and may not refer to directories.</p> <p><code>ln</code> by default creates hard links. <i>source_file</i> is linked to <i>target</i>. If <i>target</i> is a directory, another file named <i>source_file</i> is created in <i>target</i> and linked to the original <i>source_file</i>.</p>
/usr/bin/ln	If <i>target</i> is a file, its contents are overwritten. If <code>/usr/bin/ln</code> determines that the mode of <i>target</i> forbids writing, it will print the mode (see <code>chmod(1)</code>), ask for a response, and read the standard input for one line. If the response is affirmative, the link occurs, if permissible. Otherwise, the command exits.
/usr/xpg4/bin/ln	If <i>target</i> is a file and the <code>-f</code> option is not specified, <code>/usr/xpg4/bin/ln</code> will write a diagnostic message to standard error, do nothing more with the current <i>source_file</i> , and go on to any remaining <i>source_files</i> .
	<p>A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span file systems and may refer to directories.</p> <p>When creating a hard link, and the source file is itself a symbolic link, then the target will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself (<i>source_file</i>).</p> <p>File permissions for <i>target</i> may be different from those displayed with a <code>-l</code> listing of the <code>ls(1)</code> command. To display the permissions of <i>target</i> use <code>ls -lL</code>. See <code>stat(2)</code> for more information.</p>
OPTIONS	The following options are supported for both <code>/usr/bin/ln</code> and <code>/usr/xpg4/bin/ln</code> :

- f Link files without questioning the user, even if the mode of *target* forbids writing. This is the default if the standard input is not a terminal.
 - s Create a symbolic link.
- If the *-s* option is used with two arguments, *target* may be an existing directory or a non-existent file. If *target* already exists and is not a directory, an error is returned. *source_file* may be any path name and need not exist. If it exists, it may be a file or directory and may reside on a different file system from *target*. If *target* is an existing directory, a file is created in directory *target* whose name is *source_file* or the last component of *source_file*. This file is a symbolic link that references *source_file*. If *target* does not exist, a file with name *target* is created and it is a symbolic link that references *source_file*.
- If the *-s* option is used with more than two arguments, *target* must be an existing directory or an error will be returned. For each *source_file*, a link is created in *target* whose name is the last component of *source_file*. Each new *source_file* is a symbolic link to the original *source_file*. The files and *target* may reside on different file systems.

/usr/bin/ln The following options are supported for `/usr/bin/ln` only:

- n If the link is an existing file, do not overwrite the contents of the file. The *-f* option overrides this option. This is the default behavior for `/usr/xpg4/bin/ln`, and is silently ignored.

OPERANDS The following operands are supported:

- source_file* A path name of a file to be linked. This can be either a regular or special file. If the *-s* option is specified, *source_file* can also be a directory.
- target* The path name of the new directory entry to be created, or of an existing directory in which the new directory entries are to be created.

USAGE See `largefile(5)` for the description of the behavior of `ln` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `ln`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

- 0 All the specified files were linked successfully
- >0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ln(1)

/usr/bin/ln

NOTES

A symbolic link to a directory behaves differently than you might expect in certain cases. While an `ls(1)` on such a link displays the files in the pointed-to directory, an `'ls -l'` displays information about the link itself:

```
example% ln -s dir link
example% ls link
file1 file2 file3 file4
example% ls -l link
lrwxrwxrwx 1 user          7 Jan 11 23:27 link -> dir
```

When you `cd(1)` to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is `/usr` and not `/home/user/linktest`.

```
example% pwd
/home/user/linktest
example% ln -s /usr/tmp symlink
example% cd symlink
example% cd . .
example% pwd
/usr
```

C shell users can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

NAME	ln – make hard or symbolic links to files
SYNOPSIS	<pre> /usr/ucb/ln [-fs] filename [linkname] /usr/ucb/ln [-fs] pathname... directory </pre>
DESCRIPTION	<p>The <code>/usr/ucb/ln</code> utility creates an additional directory entry, called a link, to a file or directory. Any number of links can be assigned to a file. The number of links does not affect other file attributes such as size, protections, data, etc.</p> <p><i>filename</i> is the name of the original file or directory. <i>linkname</i> is the new name to associate with the file or filename. If <i>linkname</i> is omitted, the last component of <i>filename</i> is used as the name of the link.</p> <p>If the last argument is the name of a directory, symbolic links are made in that directory for each <i>pathname</i> argument; <code>/usr/ucb/ln</code> uses the last component of each <i>pathname</i> as the name of each link in the named <i>directory</i>.</p> <p>A hard link (the default) is a standard directory entry just like the one made when the file was created. Hard links can only be made to existing files. Hard links cannot be made across file systems (disk partitions, mounted file systems). To remove a file, all hard links to it must be removed, including the name by which it was first created; removing the last hard link releases the inode associated with the file.</p> <p>A symbolic link, made with the <code>-s</code> option, is a special directory entry that points to another named file. Symbolic links can span file systems and point to directories. In fact, you can create a symbolic link that points to a file that is currently absent from the file system; removing the file that it points to does not affect or alter the symbolic link itself.</p> <p>A symbolic link to a directory behaves differently than you might expect in certain cases. While an <code>ls(1)</code> on such a link displays the files in the pointed-to directory, an <code>'ls -l'</code> displays information about the link itself:</p> <pre> example% /usr/ucb/ln -s dir link example% ls link file1 file2 file3 file4 example% ls -l link lrwxrwxrwx 1 user 7 Jan 11 23:27 link -> dir </pre> <p>When you use <code>cd(1)</code> to change to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is <code>/usr</code> and not <code>/home/user/linktest</code>.</p> <pre> example% pwd /home/user/linktest example% /usr/ucb/ln -s /var/tmp symlink example% cd symlink example% cd . . </pre>

ln(1B)

```
example% pwd
/usr
```

C shell user's can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

- OPTIONS**
- `-f` Force a hard link to a directory. This option is only available to the super-user, and should be used with extreme caution.
 - `-s` Create a symbolic link or links.

USAGE See `largefile(5)` for the description of the behavior of `ln` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** The `/usr/ucb/ln` command

The commands below illustrate the effects of the different forms of the `/usr/ucb/ln` command:

```
example% /usr/ucb/ln file link
example% ls -F file link
file link
example% /usr/ucb/ln -s file symlink
example% ls -F file symlink
file symlink@
example% ls -li file link symlink
10606 -rw-r--r-- 2 user          0 Jan 12 00:06 file
10606 -rw-r--r-- 2 user          0 Jan 12 00:06 link
10607 lrwxrwxrwx 1 user          4 Jan 12 00:06 symlink -> file
example% /usr/ucb/ln -s nonesuch devoid
example% ls -F devoid
devoid@
example% cat devoid
devoid: No such file or directory
example% /usr/ucb/ln -s /proto/bin/* /tmp/bin
example% ls -F /proto/bin /tmp/bin
/proto/bin:
x*      y*      z*

/tmp/bin:
x@      y@      z@
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO `cp(1)`, `ls(1)`, `mv(1)`, `rm(1)`, `link(2)`, `readlink(2)`, `stat(2)`, `symlink(2)`, `attributes(5)`, `largefile(5)`

NOTES When the last argument is a directory, simple basenames should not be used for *pathname* arguments. If a basename is used, the resulting symbolic link points to itself:

```
example% /usr/ucb/ln -s file /tmp
example% ls -l /tmp/file
lrwxrwxrwx 1 user          4 Jan 12 00:16 /tmp/file -> file
example% cat /tmp/file
/tmp/file: Too many levels of symbolic links
```

To avoid this problem, use full pathnames, or prepend a reference to the PWD variable to files in the working directory:

```
example% rm /tmp/file
example% /usr/ucb/ln -s $PWD/file /tmp
lrwxrwxrwx 1 user          4 Jan 12 00:16 /tmp/file ->
/home/user/subdir/file
```

loadkeys(1)

NAME	loadkeys, dumpkeys – load and dump keyboard translation tables						
SYNOPSIS	loadkeys [<i>filename</i>] dumpkeys						
DESCRIPTION	<p>loadkeys reads the file specified by <i>filename</i>, and modifies the keyboard streams module's translation tables. If no file is specified, loadkeys loads the file: <code>/usr/share/lib/keytables/type_<i>tt</i>/layout_<i>dd</i></code>, where <i>tt</i> is the value returned by the KIOCTYPE <code>ioctl</code>, and <i>dd</i> is the value returned by the KIOCLAYOUT <code>ioctl</code> (see <code>kb(7M)</code>). These keytable files specify only the entries that change between the specified layout and the default layout for the particular keyboard type. On self-identifying keyboards, the value returned by the KIOCLAYOUT <code>ioctl</code> is set from the DIP switches.</p> <p>dumpkeys writes the current contents of the keyboard streams module's translation tables, in the format specified by <code>keytables(4)</code>, to the standard output.</p>						
FILES	<code>/usr/share/lib/keytables/layout_<i>dd</i></code> default keytable files						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWcsu						
Interface Stability	Evolving						
SEE ALSO	<code>kbd(1)</code> , <code>keytables(4)</code> , <code>attributes(5)</code> , <code>kb(7M)</code> , <code>usbkbm(7M)</code>						

NAME	locale – get locale-specific information
SYNOPSIS	<pre>locale [-a -m] locale [-ck] name...</pre>
DESCRIPTION	<p>The <code>locale</code> utility writes information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a <i>public locale</i> is one provided by the implementation that is accessible to the application.</p> <p>When <code>locale</code> is invoked without any arguments, it summarizes the current locale environment for each locale category as determined by the settings of the environment variables.</p> <p>When invoked with operands, it writes values that have been assigned to the keywords in the locale categories, as follows:</p> <ul style="list-style-type: none"> ■ Specifying a keyword name selects the named keyword and the category containing that keyword. ■ Specifying a category name selects the named category and all keywords in that category.
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Writes information about all available public locales. The available locales include <code>POSIX</code>, representing the POSIX locale. -c Writes the names of selected locale categories. The <code>-c</code> option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the <code>-k</code> option. -k Writes the names and values of selected keywords. The implementation may omit values for some keywords; see <code>OPERANDS</code>. -m Writes names of available charmaps; see <code>localedef(1)</code>.
OPERANDS	<p>The following operand is supported:</p> <p><i>name</i> The name of a locale category, the name of a keyword in a locale category, or the reserved name <code>charmap</code>. The named category or keyword will be selected for output. If a single <i>name</i> represents both a locale category name and a keyword name in the current locale, the results are unspecified; otherwise, both category and keyword names can be specified as <i>name</i> operands, in any sequence.</p>
EXAMPLES	<p>EXAMPLE 1 Examples of the locale utility</p> <p>In the following examples, the assumption is that locale environment variables are set as follows:</p> <pre>LANG=locale_x LC_COLLATE=locale_y</pre>

locale(1)

EXAMPLE 1 Examples of the locale utility (Continued)

The command `locale` would result in the following output:

```
LANG=locale_x
LC_CTYPE="locale_x"
LC_NUMERIC="locale_x"
LC_TIME="locale_x"
LC_COLLATE=locale_y
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=
```

The command

```
LC_ALL=POSIX locale -ck decimal_point
```

would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of `locale` to determine whether a user-supplied response is affirmative:

```
if printf "%s\n" "$response" | /usr/xpg4/bin/grep -Eq\
    "$(locale yesexpr)"
then
    affirmative processing goes here
else
    non-affirmative processing goes here
fi
```

ENVIRONMENT VARIABLES

See `environ(5)` for the descriptions of `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The `LANG`, `LC_*`, and `NLSPATH` environment variables must specify the current locale environment to be written out. These environment variables will be used if the `-a` option is not specified.

EXIT STATUS

The following exit values are returned:

```
0          All the requested information was found and output successfully.
>0        An error occurred.
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled
Interface Stability	Standard

SEE ALSO localedef(1), attributes(5), charmap(5), environ(5), locale(5), standards(5)

NOTES If LC_CTYPE or keywords in the category LC_CTYPE are specified, only the values in the range 0x00-0x7f are written out.

If LC_COLLATE or keywords in the category LC_COLLATE are specified, no actual values are written out.

localedef(1)

NAME	localedef – define locale environment												
SYNOPSIS	localedef [-c] [-C <i>compiler_options</i>] [-f <i>charmap</i>] [-i <i>sourcefile</i>] [-L <i>linker_options</i>] [-m <i>model</i>] [-W <i>cc, arg</i>] [-x <i>extensions_file</i>] <i>localename</i>												
DESCRIPTION	<p>The <code>localedef</code> utility converts source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables; see <code>environ(5)</code>.</p> <p>The utility reads source definitions for one or more locale categories belonging to the same locale from the file named in the <code>-i</code> option (if specified) or from standard input.</p> <p>Each category source definition is identified by the corresponding environment variable name and terminated by an <code>END <i>category-name</i></code> statement. The following categories are supported.</p> <table><tr><td>LC_CTYPE</td><td>Defines character classification and case conversion.</td></tr><tr><td>LC_COLLATE</td><td>Defines collation rules.</td></tr><tr><td>LC_MONETARY</td><td>Defines the format and symbols used in formatting of monetary information.</td></tr><tr><td>LC_NUMERIC</td><td>Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.</td></tr><tr><td>LC_TIME</td><td>Defines the format and content of date and time information.</td></tr><tr><td>LC_MESSAGES</td><td>Defines the format and values of affirmative and negative responses.</td></tr></table>	LC_CTYPE	Defines character classification and case conversion.	LC_COLLATE	Defines collation rules.	LC_MONETARY	Defines the format and symbols used in formatting of monetary information.	LC_NUMERIC	Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.	LC_TIME	Defines the format and content of date and time information.	LC_MESSAGES	Defines the format and values of affirmative and negative responses.
LC_CTYPE	Defines character classification and case conversion.												
LC_COLLATE	Defines collation rules.												
LC_MONETARY	Defines the format and symbols used in formatting of monetary information.												
LC_NUMERIC	Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.												
LC_TIME	Defines the format and content of date and time information.												
LC_MESSAGES	Defines the format and values of affirmative and negative responses.												
OPTIONS	<p>The following options are supported:</p> <table><tr><td>-c</td><td>Creates permanent output even if warning messages have been issued.</td></tr><tr><td>-C <i>compiler_options</i></td><td>Passes the <i>compiler_options</i> to the C compiler (<code>cc</code>). If more than one option is specified, then the options must be enclosed in quotes (" ").</td></tr><tr><td></td><td>This is an old option. Use the <code>-W <i>cc,arg</i></code> option instead.</td></tr><tr><td>-f <i>charmap</i></td><td>Specifies the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a <code>collating-symbol</code> keyword) are used. If the <code>-f</code> option is not present, the default character mapping will be used.</td></tr></table>	-c	Creates permanent output even if warning messages have been issued.	-C <i>compiler_options</i>	Passes the <i>compiler_options</i> to the C compiler (<code>cc</code>). If more than one option is specified, then the options must be enclosed in quotes (" ").		This is an old option. Use the <code>-W <i>cc,arg</i></code> option instead.	-f <i>charmap</i>	Specifies the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a <code>collating-symbol</code> keyword) are used. If the <code>-f</code> option is not present, the default character mapping will be used.				
-c	Creates permanent output even if warning messages have been issued.												
-C <i>compiler_options</i>	Passes the <i>compiler_options</i> to the C compiler (<code>cc</code>). If more than one option is specified, then the options must be enclosed in quotes (" ").												
	This is an old option. Use the <code>-W <i>cc,arg</i></code> option instead.												
-f <i>charmap</i>	Specifies the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a <code>collating-symbol</code> keyword) are used. If the <code>-f</code> option is not present, the default character mapping will be used.												

-i <i>sourcefile</i>	The path name of a file containing the source definitions. If this option is not present, source definitions will be read from standard input.
-L <i>linker_options</i>	Passes the <i>linker_options</i> to the C compiler (cc) that follows the C source filename. If more than one option is specified, then the options must be enclosed in quotes (" ").
-m <i>model</i>	<p>This is an old option. Use the -W cc,arg option instead.</p> <p>Specifies whether localedef will generate a 64-bit or a 32-bit locale object.</p> <p>Specify <i>model</i> as i1p32 to generate a 32-bit locale object. Specify lp64 to generate a 64-bit locale object. If the -m option is not specified, localedef generates a 32-bit locale object. And if no other options than -c, -f, and -i options are specified and if the system running localedef supports the 64-bit environment, localedef additionally generates a 64-bit locale object.</p>
-W cc,arg	<p>Passes <i>arg</i> options to the C compiler. Each argument must be separated from the preceding by only a comma. (A comma can be part of an argument by escaping it by an immediately preceding backslash character; the backslash is removed from the resulting argument.)</p> <p>Use this option instead of the -C and -L options.</p>
-x <i>extensions_file</i>	Specifies the name of an extension file where various localedef options are listed. See locale(5).

OPERANDS The following operand is supported:

<i>localename</i>	Identifies the locale. If the name contains one or more slash characters, <i>localename</i> will be interpreted as a path name where the created locale definitions will be stored. This capability may be restricted to users with appropriate privileges. (As a consequence of specifying one <i>localename</i> , although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)
-------------------	--

OUTPUT localedef creates a temporary C source file that represents the locale's data. localedef then calls the C compiler to compile this C source file into a shared object.

localedef(1)

If the `-m ilp32` option is specified, `localedef` calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If the `-m lp64` option is specified, `localedef` calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If the `-m` option is not specified, `localedef` calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If no other options than `-c`, `-f`, and `-i` options are specified and if the system running `localedef` supports the 64-bit environment, `localedef` additionally calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If no option to the C compiler is explicitly specified using the `-W`, `-C`, or `-L` options, `localedef` calls the C compiler with appropriate C compiler options to generate a locale object or objects.

If the `-m ilp32` option is specified, `localedef` generates a 32-bit locale object named:

localename.so.version_number

If the `-m lp64` option is specified, `localedef` generates a 64-bit locale object named:

localename.so.version_number

If the `-m` option is not specified, `localedef` generates a 32-bit locale object named:

localename.so.version_number

and, if appropriate, generates a 64-bit locale object named:

64-bit_architecture_name/localename.so.version_number

The shared object for the 32-bit environment must be moved to:

/usr/lib/locale/localename/localename.so.version_number

The shared object for the 64-bit environment on SPARC must be moved to:

/usr/lib/locale/localename/sparcv9/localename.so.version_number

`localedef` also generates a text file named *localename* that is used for information only.

ENVIRONMENT VARIABLES

See `environ(5)` for definitions of the following environment variables that affect the execution of `localedef`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- | | |
|---|---|
| 0 | No errors occurred and the locales were successfully created. |
| 1 | Warnings occurred and the locales were successfully created. |

- 2 The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.
- 3 The capability to create new locales is not supported by the implementation.
- >3 Warnings or errors occurred and no output was created.

If an error is detected, no permanent output will be created.

- FILES**
- `/usr/lib/localedef/extensions/generic_eucbc.x`
Describes what a generic EUC locale uses in the system. This file is used by default.
 - `/usr/lib/localedef/extensions/single_byte.x`
Describes a generic single-byte file used in the system.
 - `/usr/lib/locale/localename/localename.so.version_number`
The shared object for the 32-bit environment.
 - `/usr/lib/locale/localename/sparcv9/localename.so.version_number`
The shared object for the 64-bit environment on SPARC.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

SEE ALSO `locale(1)`, `nl_langinfo(3C)`, `strftime(3C)`, `attributes(5)`, `charmap(5)`, `environ(5)`, `extensions(5)`, `locale(5)`, `standards(5)`

WARNINGS If warnings occur, permanent output will be created if the `-c` option was specified. The following conditions will cause warning messages to be issued:

- If a symbolic name not found in the `charmap` file is used for the descriptions of the `LC_CTYPE` or `LC_COLLATE` categories (for other categories, this will be an error conditions).
- If optional keywords not supported by the implementation are present in the source.

logger(1)

NAME	logger – add entries to the system log
SYNOPSIS	logger [-i] [-f <i>file</i>] [-p <i>priority</i>] [-t <i>tag</i>] [<i>message</i>] ...
DESCRIPTION	The logger command provides a method for adding one-line entries to the system log file from the command line. One or more <i>message</i> arguments can be given on the command line, in which case each is logged immediately. If this is unspecified, either the file indicated with -f or the standard input is added to the log. Otherwise, a <i>file</i> can be specified, in which case each line in the file is logged. If neither is specified, logger reads and logs messages on a line-by-line basis from the standard input.
OPTIONS	The following options are supported: -f <i>file</i> Uses the contents of <i>file</i> as the message to log. -i Logs the process ID of the logger process with each line. -p <i>priority</i> Enters the message with the specified <i>priority</i> . The message priority can be specified numerically, or as a <i>facility.level</i> pair. For example, '-p local3.info' assigns the message priority to the info level in the local3 facility. The default priority is user.notice. -t <i>tag</i> Marks each line added to the log with the specified <i>tag</i> .
OPERANDS	The following operand is supported: <i>message</i> One of the string arguments whose contents are concatenated together, in the order specified, separated by single space characters.
EXAMPLES	EXAMPLE 1 Examples of the logger command The following example: example% logger System rebooted logs the message 'System rebooted' to the default priority level notice to be treated by syslogd as are other messages to the facility user. The next example: example% logger -p local0.notice -t HOSTIDM -f /dev/idmc reads from the file /dev/idmc and logs each line in that file as a message with the tag 'HOSTIDM' at priority level notice to be treated by syslogd as are other messages to the facility local0.
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of logger : LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.
EXIT STATUS	The following exit values are returned:

logger(1)

0 Successful completion.
>0 An error occurred.

ATTRIBUTES

logger(1B)

NAME logger – add entries to the system log

SYNOPSIS /usr/ucb/logger [-f *filename*] [-i] [-p *priority*] [-t *tag*] mm [*message*]...

DESCRIPTION The logger utility provides a method for adding one-line entries to the system log file from the command line. One or more *message* arguments can be given on the command line, in which case each is logged immediately. If *message* is unspecified, either the file indicated with -f or the standard input is added to the log. Otherwise, a *filename* can be specified, in which case each line in the file is logged. If neither is specified, logger reads and logs messages on a line-by-line basis from the standard input.

OPTIONS The following options are supported:

- i Log the process ID of the logger process with each line.
- f *filename* Use the contents of *filename* as the message to log.
- p *priority* Enter the message with the specified *priority*. The message priority can be specified numerically, or as a *facility.level* pair. For example, '-p local3.info' assigns the message priority to the info level in the local3 facility. The default priority is user.notice.
- t *tag* Mark each line added to the log with the specified *tag*.

EXAMPLES

EXAMPLE 1 Logging a message

The command:

```
example% logger System rebooted
```

will log the message 'System rebooted' to the facility at priority notice to be treated by syslogd as other messages to the facility notice are.

EXAMPLE 2 Logging messages from a file

The command:

```
example% logger -p local0.notice -t HOSTIDM -f /dev/idmc
```

will read from the file /dev/idmc and will log each line in that file as a message with the tag 'HOSTIDM' at priority notice to be treated by syslogd as other messages to the facility local0 are.

login(1)

NAME	login – sign on to the system
SYNOPSIS	login [-p] [-d <i>device</i>] [-h <i>hostname</i> [<i>terminal</i>] -r <i>hostname</i>] [<i>name</i> [<i>environ</i>] ...]
DESCRIPTION	<p>The <code>login</code> command is used at the beginning of each terminal session to identify oneself to the system. <code>login</code> is invoked by the system when a connection is first established, after the previous user has terminated the login shell by issuing the <code>exit</code> command.</p> <p>If <code>login</code> is invoked as a command, it must replace the initial command interpreter. To invoke <code>login</code> in this fashion, type:</p> <pre>exec login</pre> <p>from the initial shell. The C shell and Korn shell have their own builtins of <code>login</code>. See <code>ksh(1)</code> and <code>csh(1)</code> for descriptions of <code>login</code> builtins and usage.</p> <p><code>login</code> asks for your user name, if it is not supplied as an argument, and your password, if appropriate. Where possible, echoing is turned off while you type your password, so it will not appear on the written record of the session.</p> <p>If you make any mistake in the login procedure, the message:</p> <pre>Login incorrect</pre> <p>is printed and a new login prompt will appear. If you make five incorrect login attempts, all five may be logged in <code>/var/adm/loginlog</code>, if it exists. The TTY line will be dropped.</p> <p>If password aging is turned on and the password has "aged" (see <code>passwd(1)</code> for more information), the user is forced to change the password. In this case the <code>/etc/nsswitch.conf</code> file is consulted to determine password repositories (see <code>nsswitch.conf(4)</code>). The password update configurations supported are limited to the following five cases.</p> <ul style="list-style-type: none">■ <code>passwd: files</code>■ <code>passwd: files nis</code>■ <code>passwd: files nisplus</code>■ <code>passwd: compat (==> files nis)</code>■ <code>passwd: compat (==> files nisplus)</code> <code>passwd_compat: nisplus</code> <p>Failure to comply with the configurations will prevent the user from logging onto the system because <code>passwd(1)</code> will fail. If you do not complete the login successfully within a certain period of time, it is likely that you will be silently disconnected.</p> <p>After a successful login, accounting files are updated. Device owner, group, and permissions are set according to the contents of the <code>/etc/logindevperm</code> file, and the time you last logged in is printed (see <code>logindevperm(4)</code>).</p>

The user-ID, group-ID, supplementary group list, and working directory are initialized, and the command interpreter (usually `ksh`) is started.

The basic *environment* is initialized to:

```
HOME=your-login-directory
LOGNAME=your-login-name
PATH=/usr/bin:
SHELL=last-field-of-passwd-entry
MAIL=/var/mail/
TZ=timezone-specification
```

For Bourne shell and Korn shell logins, the shell executes `/etc/profile` and `$HOME/.profile`, if it exists. For C shell logins, the shell executes `/etc/.login`, `$HOME/.cshrc`, and `$HOME/.login`. The default `/etc/profile` and `/etc/.login` files check quotas (see `quota(1M)`), print `/etc/motd`, and check for mail. None of the messages are printed if the file `$HOME/.hushlogin` exists. The name of the command interpreter is set to `-` (dash), followed by the last component of the interpreter's path name, for example, `-sh`.

If the *login-shell* field in the password file (see `passwd(4)`) is empty, then the default command interpreter, `/usr/bin/sh`, is used. If this field is `*` (asterisk), then the named directory becomes the root directory. At that point, `login` is re-executed at the new level, which must have its own root structure.

The environment may be expanded or modified by supplying additional arguments to `login`, either at execution time or when `login` requests your login name. The arguments may take either the form `xxx` or `xxx=yyy`. Arguments without an `=` (equal sign) are placed in the environment as:

```
Ln=xxx
```

where *n* is a number starting at 0 and is incremented each time a new variable name is required. Variables containing an `=` (equal sign) are placed in the environment without modification. If they already appear in the environment, then they replace the older values.

There are two exceptions: The variables `PATH` and `SHELL` cannot be changed. This prevents people logged into restricted shell environments from spawning secondary shells that are not restricted. `login` understands simple single-character quoting conventions. Typing a `\` (backslash) in front of a character quotes it and allows the inclusion of such characters as spaces and tabs.

Alternatively, you can pass the current environment by supplying the `-p` flag to `login`. This flag indicates that all currently defined environment variables should be passed, if possible, to the new environment. This option does not bypass any environment variable restrictions mentioned above. Environment variables specified on the `login` line take precedence, if a variable is passed by both methods.

login(1)

SECURITY

To enable remote logins by root, edit the `/etc/default/login` file by inserting a # (pound sign) before the `CONSOLE=/dev/console` entry. See FILES.

The `login` command uses pam(3PAM) for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `login`. Here is a partial `pam.conf` file with entries for the `login` command using the UNIX authentication, account management, and session management modules:

```
login auth      required pam_authtok_get.so.1
login auth      required pam_dhkeys.so.1
login auth      required pam_unix_auth.so.1
login auth      required pam_dial_auth.so.1

login account   requisite pam_roles.so.1
login account   required pam_projects.so.1
login account   required pam_unix_account.so.1

login session   required pam_unix_session.so.1
```

The Password Management stack looks like the following:

```
other password required pam_dhkeys.so.1
other password requisite pam_authtok_get.so.1
other password requisite pam_authtok_check.so.1
other password required pam_authtok_store.so.1
```

If there are no entries for the service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

When `login` is invoked through `rlogind` or `telnetd`, the service name used by PAM is `rlogin` or `telnet`, respectively.

OPTIONS

The following options are supported:

<code>-d device</code>	<code>login</code> accepts a device option, <i>device</i> . <i>device</i> is taken to be the path name of the TTY port <code>login</code> is to operate on. The use of the device option can be expected to improve <code>login</code> performance, since <code>login</code> will not need to call <code>ttynam(3C)</code> . The <code>-d</code> option is available only to users whose UID and effective UID are root. Any other attempt to use <code>-d</code> will cause <code>login</code> to quietly exit.
<code>-h hostname [terminal]</code>	Used by <code>in.telnetd(1M)</code> to pass information about the remote host and terminal type.
<code>-p</code>	Used to pass environment variables to the <code>login</code> shell.

	<code>-r hostname</code>	Used by <code>in.rlogind(1M)</code> to pass information about the remote host.
EXIT STATUS	The following exit values are returned:	
	0	Successful operation.
	non-zero	Error.
FILES	<code>\$HOME/.cshrc</code>	initial commands for each csh
	<code>\$HOME/.hushlogin</code>	suppresses login messages
	<code>\$HOME/.login</code>	user's login commands for csh
	<code>\$HOME/.profile</code>	user's login commands for sh and ksh
	<code>\$HOME/.rhosts</code>	private list of trusted hostname/username combinations
	<code>/etc/.login</code>	system-wide csh login commands
	<code>/etc/issue</code>	issue or project identification
	<code>/etc/logindevperm</code>	login-based device permissions
	<code>/etc/motd</code>	message-of-the-day
	<code>/etc/nologin</code>	message displayed to users attempting to login during machine shutdown
	<code>/etc/passwd</code>	password file
	<code>/etc/profile</code>	system-wide sh and ksh login commands
	<code>/etc/shadow</code>	list of users' encrypted passwords
	<code>/usr/bin/sh</code>	user's default command interpreter
	<code>/var/adm/lastlog</code>	time of last login
	<code>/var/adm/loginlog</code>	record of failed login attempts
	<code>/var/adm/utmpx</code>	accounting
	<code>/var/adm/wtmpx</code>	accounting
	<code>/var/mail/your-name</code>	mailbox for user <i>your-name</i>
	<code>/etc/default/login</code>	Default value can be set for the following flags in <code>/etc/default/login</code> . For example: <code>TIMEZONE=EST5EDT</code> TIMEZONE Sets the TZ environment variable of the shell (see <code>environ(5)</code>). HZ Sets the HZ environment variable of the shell.

login(1)

ULIMIT

Sets the file size limit for the login. Units are disk blocks. Default is zero (no limit).

CONSOLE

If set, root can login on that device only. This will not prevent execution of remote commands with `rsh(1)`. Comment out this line to allow login by root.

PASSREQ

Determines if login requires a non-null password.

ALTSHELL

Determines if login should set the `SHELL` environment variable.

PATH

Sets the initial shell `PATH` variable.

SUPATH

Sets the initial shell `PATH` variable for root.

TIMEOUT

Sets the number of seconds (between 0 and 900) to wait before abandoning a login session.

UMASK

Sets the initial shell file creation mode mask. See `umask(1)`.

SYSLOG

Determines whether the `syslog(3C)` `LOG_AUTH` facility should be used to log all root logins at level `LOG_NOTICE` and multiple failed login attempts at `LOG_CRIT`.

DISABLETIME

If present, and greater than zero, the number of seconds that `login` will wait after `RETRIES` failed attempts or the PAM framework returns `PAM_ABORT`. Default is 20 seconds. Minimum is 0 seconds. No maximum is imposed.

SLEEPTIME

If present, sets the number of seconds to wait before the login failure message is printed to the screen. This is for any login failure other than `PAM_ABORT`. Another login attempt is allowed, providing `RETRIES` has not been reached or the PAM framework is returned `PAM_MAXTRIES`. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

RETRIES

Sets the number of retries for logging in (see pam(3PAM)). The default is 5.

SYSLOG_FAILED_LOGINS

Used to determine how many failed login attempts will be allowed by the system before a failed login message is logged, using the syslog(3C) LOG_NOTICE facility. For example, if the variable is set to 0, login will log *all* failed login attempts.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO csh(1), exit(1), ksh(1), mail(1), mailx(1), newgrp(1), passwd(1), rlogin(1), rsh(1), sh(1), shell_builtins(1), telnet(1), umask(1), in.rlogind(1M), in.telnetd(1M), logins(1M), quota(1M), su(1M), syslogd(1M), useradd(1M), userdel(1M), pam(3PAM), rcmd(3SOCKET), syslog(3C), ttyname(3C), auth_attr(4), exec_attr(4), hosts.equiv(4), issue(4), logindevperm(4), loginlog(4), nologin(4), nsswitch.conf(4), pam.conf(4), passwd(4), profile(4), shadow(4), user_attr(4), utmpx(4), wtmpx(4), attributes(5), environ(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5), pam_authok_check(5), pam_authok_get(5), pam_authok_store(5), pam_dhkeys(5), pam_passwd_auth(5), termio(7I)

DIAGNOSTICS

Login incorrect

The user name or the password cannot be matched.

Not on system console

Root login denied. Check the CONSOLE setting in /etc/default/login.

No directory! Logging in with home=/

The user's home directory named in the passwd(4) database cannot be found or has the wrong permissions. Contact your system administrator.

No shell

Cannot execute the shell named in the passwd(4) database. Contact your system administrator.

NO LOGINS: System going down in *N* minutes

The machine is in the process of being shut down and logins have been disabled.

WARNINGS

Users with a UID greater than 76695844 are not subject to password aging, and the system does not record their last login time.

login(1)

If you use the `CONSOLE` setting to disable root logins, you should arrange that remote command execution by root is also disabled. See `rsh(1)`, `rcmd(3SOCKET)`, and `hosts.equiv(4)` for further details.

NOTES The `pam_unix(5)` module might not be supported in a future release. Similar functionality is provided by `pam_unix_account(5)`, `pam_unix_auth(5)`, `pam_unix_session(5)`, `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, and `pam_passwd_auth(5)`.

NAME	logname – return user’s login name						
SYNOPSIS	logname						
DESCRIPTION	The logname utility will write the user’s login name to standard output. The login name is the string that would be returned by the <code>getlogin(3C)</code> function. Under the conditions where <code>getlogin()</code> would fail, logname will write a diagnostic message to standard error and exit with a non-zero exit status.						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of logname: <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS	The following error values are returned: <table> <tr> <td>0</td> <td>Successful completion.</td> </tr> <tr> <td>>0</td> <td>An error occurred.</td> </tr> </table>	0	Successful completion.	>0	An error occurred.		
0	Successful completion.

NAME	look – find words in the system dictionary or lines in a sorted list				
SYNOPSIS	<code>/usr/bin/look [-d] [-f] [-tc] string [filename]</code>				
DESCRIPTION	<p>The <code>look</code> command consults a sorted <i>filename</i> and prints all lines that begin with <i>string</i>.</p> <p>If no <i>filename</i> is specified, <code>look</code> uses <code>/usr/share/lib/dict/words</code> with collating sequence <code>-df</code>.</p> <p><code>look</code> limits the length of a word to search for to 256 characters.</p>				
OPTIONS	<p><code>-d</code> Dictionary order. Only letters, digits, TAB and SPACE characters are used in comparisons.</p> <p><code>-f</code> Fold case. Upper case letters are not distinguished from lower case in comparisons.</p> <p><code>-tc</code> Set termination character. All characters to the right of <i>c</i> in <i>string</i> are ignored.</p>				
FILES	<code>/usr/share/lib/dict/words</code> spelling list				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

Availability	SUNWesu				
SEE ALSO	<code>grep(1)</code> , <code>sort(1)</code> , <code>attributes(5)</code>				

lookbib(1)

NAME	lookbib – find references in a bibliographic database				
SYNOPSIS	lookbib <i>database</i>				
DESCRIPTION	<p>A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a ‘%’, followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with ‘%’.</p> <p>The <code>lookbib</code> utility uses an inverted index made by <code>indxbib</code> to find sets of bibliographic references. It reads keywords typed after the ‘>’ prompt on the terminal, and retrieves records containing all these keywords. If nothing matches, nothing is returned except another ‘>’ prompt.</p> <p>It is possible to search multiple databases, as long as they have a common index made by <code>indxbib(1)</code>. In that case, only the first argument given to <code>indxbib</code> is specified to <code>lookbib</code>.</p> <p>If <code>lookbib</code> does not find the index files (the <code>.i[abc]</code> files), it looks for a reference file with the same name as the argument, without the suffixes. It creates a file with a <code>.ig</code> suffix, suitable for use with <code>fgrep</code> (see <code>grep(1)</code>). <code>lookbib</code> then uses this <code>fgrep</code> file to find references. This method is simpler to use, but the <code>.ig</code> file is slower to use than the <code>.i[abc]</code> files, and does not allow the use of multiple reference files.</p>				
FILES	<p><code>x.ia</code> <code>x.ib</code> <code>x.ic</code> index files <code>x.ig</code> reference file</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWdoc</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWdoc

Availability	SUNWdoc				
SEE ALSO	<code>addbib(1)</code> , <code>grep(1)</code> , <code>indxbib(1)</code> , <code>refer(1)</code> , <code>roffbib(1)</code> , <code>sortbib(1)</code> , <code>attributes(5)</code>				
BUGS	Probably all dates should be indexed, since many disciplines refer to literature written in the 1800s or earlier.				

NAME	lorder – find ordering relation for an object or library archive					
SYNOPSIS	lorder <i>filename...</i>					
DESCRIPTION	<p>The input is one or more object or library archive <i>filenames</i> (see <code>ar(1)</code>). The standard output is a list of pairs of object file or archive member names; the first file of the pair refers to external identifiers defined in the second. The output may be processed by <code>tsort(1)</code> to find an ordering of a library suitable for one-pass access by <code>ld</code>. Note that the link editor <code>ld</code> is capable of multiple passes over an archive in the portable archive format (see <code>ar(3HEAD)</code>) and does not require that <code>lorder</code> be used when building an archive. The usage of the <code>lorder</code> command may, however, allow for a more efficient access of the archive during the link edit process.</p> <p>The following example builds a new library from existing <code>.o</code> files.</p> <pre>ar -cr library `lorder *.o tsort `</pre>					
FILES	<code>TMPDIR/*symref</code>	temporary files				
	<code>TMPDIR/*symdef</code>	temporary files				
	<code>TMPDIR</code>	usually <code>/var/tmp</code> but can be redefined by setting the environment variable <code>TMPDIR</code> (see <code>tmpnam(3)</code> in <code>tmpnam(3C)</code>)				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:					
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWbtool</td> </tr> </tbody> </table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbtool
ATTRIBUTE TYPE	ATTRIBUTE VALUE					
Availability	SUNWbtool					
SEE ALSO	<code>ar(1)</code> , <code>ld(1)</code> , <code>tsort(1)</code> , <code>tmpnam(3C)</code> , <code>ar(3HEAD)</code> , <code>attributes(5)</code>					
NOTES	<p><code>lorder</code> will accept as input any object or archive file, regardless of its suffix, provided there is more than one input file. If there is but a single input file, its suffix must be <code>.o</code>.</p> <p>The length of the filename for <code>TMPDIR</code> is limited to whatever <code>sed</code> allows.</p>					

lp(1)

NAME	lp – submit print request						
SYNOPSIS	<pre>lp [-c] [-m] [-p] [-s] [-w] [-d destination] [-f form-name] [-H special-handling] [-n number] [-o option] [-P page-list] [-q priority-level] [-S character-set print-wheel] [-t title] [-T content-type] [-r]] [-y mode-list] [file...] lp -i request-ID... [-c] [-m] [-p] [-s] [-w] [-d destination] [-f form-name] [-H special-handling] [-n number] [-o option] [-P page-list] [-q priority-level] [-S character-set print-wheel] [-t title] [-T content-type] [-r]] [-y mode-list]</pre>						
DESCRIPTION	<p>The <code>lp</code> utility submits print requests to a destination. There are two formats of the <code>lp</code> command.</p> <p>The first form of <code>lp</code> prints files (<i>file</i>) and associated information (collectively called a <i>print request</i>). If <i>file</i> is not specified, <code>lp</code> assumes the standard input. Use a hyphen (-) with <i>file</i> to specify the standard input. Files are printed in the order in which they appear on the command line.</p> <p>The second form of <code>lp</code> changes print request options. This form of <code>lp</code> can only be used on a Solaris 2.6 Operating Environment or compatible versions of the LP print server. The print request identified by <i>request-ID</i> is changed according to the printing options specified. The printing options available are the same as those with the first form of the <code>lp</code>. If the request has finished printing when the <code>lp</code> command is executed, the change is rejected. If the request is in the process of printing, it will be stopped and restarted from the beginning (unless the <code>-P</code> option has been given).</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p>						
OPTIONS	<p>Printers that have a 4.x or BSD-based print server are not configured to handle BSD protocol extensions. <code>lp</code> handles print requests sent to such destinations differently (see NOTES).</p> <p>The following options are supported:</p> <table><tr><td><code>-c</code></td><td>Copies <i>file</i> before printing.</td></tr><tr><td></td><td>Unless <code>-c</code> is specified, users should not remove any <i>file</i> before the print request has completely printed. Changes made to <i>file</i> after the print request is made but before it is printed will be reflected in the printed output. <i>file</i> will be linked (as opposed to copied).</td></tr><tr><td><code>-d destination</code></td><td>Prints <i>file</i> on a specific destination. The <code>-d</code> option is used to set the destination only when the job is first created. (Note: To move existing jobs to a different destination, see <code>lpmove(1M)</code>.) <i>destination</i> can be either a printer or a class of printers (see <code>lpadmin(1M)</code>).</td></tr></table>	<code>-c</code>	Copies <i>file</i> before printing.		Unless <code>-c</code> is specified, users should not remove any <i>file</i> before the print request has completely printed. Changes made to <i>file</i> after the print request is made but before it is printed will be reflected in the printed output. <i>file</i> will be linked (as opposed to copied).	<code>-d destination</code>	Prints <i>file</i> on a specific destination. The <code>-d</code> option is used to set the destination only when the job is first created. (Note: To move existing jobs to a different destination, see <code>lpmove(1M)</code> .) <i>destination</i> can be either a printer or a class of printers (see <code>lpadmin(1M)</code>).
<code>-c</code>	Copies <i>file</i> before printing.						
	Unless <code>-c</code> is specified, users should not remove any <i>file</i> before the print request has completely printed. Changes made to <i>file</i> after the print request is made but before it is printed will be reflected in the printed output. <i>file</i> will be linked (as opposed to copied).						
<code>-d destination</code>	Prints <i>file</i> on a specific destination. The <code>-d</code> option is used to set the destination only when the job is first created. (Note: To move existing jobs to a different destination, see <code>lpmove(1M)</code> .) <i>destination</i> can be either a printer or a class of printers (see <code>lpadmin(1M)</code>).						

	Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<i>.../service/printer/...</i>) names. See <i>printers.conf</i> (4) for information regarding the naming conventions for atomic and FNS names and <i>standards</i> (5) for information regarding POSIX.
<code>-f <i>form-name</i></code>	Prints <i>file</i> on <i>form-name</i> . The LP print service ensures that the form is mounted on the printer. The print request is rejected if the printer does not support <i>form-name</i> , if <i>form-name</i> is not defined for the system, or if the user is not allowed to use <i>form-name</i> (see <i>lpforms</i> (1M)).
<code>-H <i>special-handling</i></code>	Prints the print request according to the value of <i>special-handling</i> . The following <i>special-handling</i> values are acceptable: <p><code>hold</code> Do not print the print request until notified. If printing has already begun, stop it. Other print requests will go ahead of a request that has been put on hold (<i>held print request</i>) until the print request is resumed.</p> <p><code>resume</code> Resume a held print request. If the print request had begun to print when held, it will be the next print request printed, unless it is superseded by an <i>immediate</i> print request.</p> <p><code>immediate</code> Print the print request next. If more than one print request is assigned, the most recent print request is printed next. If a print request is currently printing on the desired printer, a <code>hold</code> request must be issued to allow the immediate request to print. The <code>immediate</code> request is only available to LP administrators.</p>
<code>-i <i>request-ID</i></code>	Changes options for the print request identified by <i>request-ID</i> . There must be a space between <code>-i</code> and <i>request-ID</i> . This option applies only to jobs that are in a local queue on a print server.
<code>-m</code>	Sends mail after <i>file</i> has printed (see <i>mail</i> (1)). By default, no mail is sent upon normal completion of a print request.
<code>-n <i>number</i></code>	Prints a specific number of copies of <i>file</i> . Specify <i>number</i> as a digit. The default for <i>number</i> is 1.

lp(1)

-o *option*

Specifies printer-dependent *options*. Specify several options by specifying -o *option* multiple times (-o *option* -o *option* -o *option*). Printer-dependent options may also be specified using the -o keyletter once, followed by a list of options enclosed in double quotes (-o " *option option option* "). The following options are valid:

nobanner

Does not print a banner page with the request. This option can be disallowed by the LP administrator.

nofilebreak

Prints multiple files without inserting a form feed between them.

length=*number*i | *number*c | *number*

Prints the print request with pages of a specific length in inches, centimeters, or number of lines. Append the letter *i* for inches or *c* for centimeters to *number*. Indicate the number of lines by specifying *number* alone. length=66 indicates a page length of 66 lines. length=11*i* indicates a page length of 11 inches. length=27.94*c* indicates a page length of 27.94 centimeters.

This option may not be used with the -f option.

width=*number*i | *number*c | *number*

Prints the print request with pages of a specific width in inches, centimeters, or number of columns. Append the letter *i* for inches or *c* for centimeters to *number*. Indicate the number of columns by specifying *number* alone. width=65 indicates a page width of 65 columns. width=6.5*i* indicates a page width of 6.5 inches. width=10*c* indicates a page width of 10 centimeters.

This option may not be used with the -f option.

lpi=*number*

Prints the print request with the line pitch set to *number* lines in an inch. Use *number* to specify the number of lines in an inch.

This option may not be used with the -f option.

cpi=*n* | *pica* | *elite* | *compressed*

Prints the print request with the character pitch set to *number* characters in an inch. Use *number* to specify the number of characters in an inch. Use

`pica` to set character pitch to pica (10 characters per inch), or `elite` to set character pitch to elite (12 characters per inch) Use `compressed` to set character pitch to as many characters as the printer can handle. There is no standard number of characters per inch for all printers; see the `terminfo` database (see `terminfo(4)`) for the default character pitch for your printer. This option may not be used with the `-f` option.

`stty=stty-option-list`

Prints the request using a list of options valid for the `stty` command (see `stty(1)`). Enclose the list in single quotes (`' '`) if it contains blanks.

`-P page-list`

Prints the pages specified in *page-list* in ascending order. Specify *page-list* as a of range of numbers, single page number, or a combination of both.

The `-P` option can only be used if there is a filter available to handle it; otherwise, the print request will be rejected.

`-p`

Enables notification on completion of the print request. Delivery of the notification is dependent on additional software.

`-q priority-level`

Assigns the print request a priority in the print queue. Specify *priority-level* as an integer between from 0 and 39. Use 0 to indicate the highest priority; 39 to indicate the lowest priority. If no priority is specified, the default priority for a print service is assigned by the LP administrator. The LP administrator may also assign a default priority to individual users.

`-s`

Suppresses the display of messages sent from `lp`.

`-S character-set |
-S print-wheel`

Prints the request using the *character-set* or *print-wheel*. If a form was requested and requires a character set or print wheel other than the one specified with the `-S` option, the request is rejected. Printers using mountable print wheels or font cartridges use the print wheel or font cartridge mounted at the time of the print request, unless the `-S` option is specified.

Printers Using Print Wheels: If *print wheel* is not one listed by the LP administrator as acceptable for the printer the request is rejected unless the print wheel is already mounted on the printer.

lp(1)

	<p>Printers Using Selectable or Programmable Character Sets: If the <code>-S</code> option is not specified, <code>lp</code> uses the standard character set. If <i>character-set</i> is not defined in the <code>terminfo</code> database for the printer (see <code>terminfo(4)</code>), or is not an alias defined by the LP administrator, the request is rejected.</p>
<code>-t title</code>	<p>Prints a title on the banner page of the output. Enclose <i>title</i> in quotes if it contains blanks. If <i>title</i> is not specified, the name of the file is printed on the banner page.</p>
<code>-T content-type [-r]</code>	<p>Prints the request on a printer that can support the specified <i>content-type</i>. If no printer accepts this type directly, a filter will be used to convert the content into an acceptable type. If the <code>-r</code> option is specified, a filter will not be used. If <code>-r</code> is specified, and no printer accepts the <i>content-type</i> directly, the request is rejected. If the <i>content-type</i> is not acceptable to any printer, either directly or with a filter, the request is rejected.</p>
<code>-w</code>	<p>Writes a message on the user's terminal after the <i>files</i> have been printed. If the user is not logged in, then mail will be sent instead.</p>
<code>-y mode-list</code>	<p>Prints the request according to the printing modes listed in <i>mode-list</i>. The allowed values for <i>mode-list</i> are locally defined.</p> <p>This option may be used only if there is a filter available to handle it; otherwise, the print request will be rejected.</p>
OPERANDS	<p>The following operand is supported:</p>
<i>file</i>	<p>The name of the file to be printed. Specify <i>file</i> as a pathname or as a hyphen (<code>-</code>) to indicate the standard input. If <i>file</i> is not specified, <code>lp</code> uses the standard input.</p>
USAGE	<p>See <code>largefile(5)</code> for the description of the behavior of <code>lp</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).</p>
ENVIRONMENT VARIABLES	<p>See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>lp</code>: <code>LANG</code>, <code>LC_ALL</code>, <code>LC_CTYPE</code>, <code>LC_MESSAGES</code>, <code>NLSPATH</code>, and <code>PATH</code>.</p>
<code>LC_TIME</code>	<p>Determine the format and contents of date and time strings displayed in the <code>lp</code> banner page, if any.</p>
<code>LPDEST</code>	<p>Determine the destination. If the <code>LPDEST</code> environment variable is not set, the <code>PRINTER</code> environment variable shall be used. The <code>-d</code></p>

dest option takes precedence over LPDEST. Results are undefined when *-d* is not specified and LPDEST contains a value that is not a valid destination name.

PRINTER Determine the output device or destination. If the LPDEST and PRINTER environment variables are not set, an unspecified output device is used. The *-d dest* option and the LPDEST environment variable shall take precedence over PRINTER. Results are undefined when *-d* is not specified, LPDEST is unset, and PRINTER contains a value that is not a valid device or destination name.

TZ Determine the timezone used to calculate date and time strings displayed in the lp banner page, if any. If TZ is unset or null, an unspecified default timezone shall be used.

EXIT STATUS The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

FILES

/var/spool/lp/*	LP print queue.
\$HOME/.printers	User-configurable printer database.
/etc/printers.conf	System printer configuration database.
printers.conf.byname	NIS version of /etc/printers.conf.
printers.org_dir	NIS+ version of /etc/printers.conf.
fns.ctx_dir. <i>domain</i>	FNS version of /etc/printers.conf.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
CSI	Enabled (see NOTES)
Interface Stability	Standard

SEE ALSO cancel(1), enable(1), lpq(1B), lpr(1B), lprm(1B), lpstat(1), mail(1), postprint(1), pr(1), stty(1), accept(1M), lpadmin(1M), lpfilter(1M), lpforms(1M), lpmove(1M), lpsched(1M), lpshut(1M), lpssystem(1M), lpusers(1M), nsswitch.conf(4), printers(4), printers.conf(4), terminfo(4), attributes(5), environ(5), largefile(5), standards(5)

NOTES CSI-capability assumes that printer names are composed of ASCII characters.

lp(1)

Print jobs are assumed to contain one type of data. That type of data is either specified on the command line or autodetected (simple, PostScript) based on the contents of the first file in the job.

Printers that have a 4.x or BSD-based print server, are not configured to handle BSD protocol extensions. `lp` handles print requests sent to such printers in the following ways:

1. Print requests with more than 52 filenames will be truncated to 52 files. `lp` displays a warning message.
2. The `-f`, `-H`, `-o`, `-P`, `-p`, `-q`, `-S`, `-T`, and `-y` options may require a protocol extension to pass to a print server. If `lp` cannot handle the print request, it displays a warning message.

LP administrators enable protocol extensions by setting a printer's `bsdaddr` entry in `/etc/printers.conf`. Changing the `bsdaddr` entry in `/etc/printers.conf` to:

```
destination:bsdaddr=server,destination,Solaris
```

generates a set of BSD print protocol extensions that can be processed by a Solaris print server. `lp` supports only Solaris protocol extensions at this time.

NAME	lpc – line printer control program
SYNOPSIS	<code>/usr/ucb/lpc [command [parameter...]]</code>
DESCRIPTION	<p>The lpc utility controls the operation of local printers.</p> <p>Use lpc to perform the following functions:</p> <ul style="list-style-type: none"> ■ start or stop a printer, ■ disable or enable a printer’s spooling queue, ■ rearrange the order of jobs in a print queue, or ■ display the status of a printer print queue and printer daemon. <p>lpc can be run from the command line or interactively. Specifying lpc with the optional <i>command</i> and <i>parameter</i> arguments causes lpc to interpret the first argument as an lpc command, and all other arguments as parameters to that command. Specifying lpc without arguments causes it to run interactively, prompting the user for lpc commands with lpc>. By redirecting the standard input, lpc can read commands from a file.</p>
USAGE	<p>lpc commands may be typed in their entirety or abbreviated to an unambiguous substring. Some lpc commands are available to all users; others are available only to super-users.</p> <p>All users may execute the following lpc commands:</p> <p>? [<i>command ...</i>] help [<i>command ...</i>] Displays a short description of <i>command</i>. <i>command</i> is an lpc command. If <i>command</i> is not specified, displays a list of lpc commands.</p> <p>exit quit Exits from lpc.</p> <p>status [<i>all</i> <i>printer ...</i>] Displays the status of print daemons and print queues. <i>all</i> specifies that this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <code>printers.conf(4)</code> for information regarding naming conventions for atomic names.</p> <p>Only a super-user may execute the following lpc commands:</p> <p>abort [<i>all</i> <i>printer ...</i>] Terminates an active spooling daemon. Disables printing (by preventing new daemons from being started by lpr(1B)) for <i>printer</i>. <i>all</i> specifies this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <code>printers.conf(4)</code> for information regarding naming conventions for atomic names.</p>

lpc(1B)

`clean [all | printer ...]`

Removes files created in the print spool directory by the print daemon from *printer*'s print queue. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`disable [all | printer ...]`

Turns off the print queue for *printer*. Prevents new printer jobs from being entered into the print queue for *printer* by `lpr(1B)`. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`down [all | printer ...] [message]`

Turns the queue for *printer* off and disables printing on *printer*. Inserts *message* in the printer status file. *message* does not need to be quoted; multiple arguments to *message* are treated as arguments are to `echo(1)`. Use `down` to take a printer down and inform users. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`enable [all | printer ...]`

Enables `lpr(1B)` to add new jobs in the spool queue. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`restart [all | printer ...]`

Attempts to start a new printer daemon. `restart` is useful when a print daemon dies unexpectedly and leaves jobs in the print queue. `all` specifies that this command is performed on all locally attached printers. *printer* indicates that this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`start [all | printer ...]`

Enables printing. Starts a spooling daemon for the *printer*. `all` specifies that this command is performed on all locally attached printers. *printer* indicates the command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`stop [all | printer ...]`

Stops a spooling daemon after the current job is complete. Disables printing at that time. `all` specifies that this command is performed on all locally attached printers.

printer indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`topq printer [request-ID ...] [user ...]`

Moves *request-ID* or print jobs belonging to *user* on *printer* to the beginning of the print queue. Specify *user* as a user's login name. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`up [all | printer ...]`

Turns the queue for *printer* on and enables printing on *printer*. Deletes the message in the printer status file (inserted by `down`). Use `up` to undo the effects of `down`. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

EXIT STATUS The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

FILES `/var/spool/lp/*` LP print queue.
`/var/spool/lp/system/pstatus` Printer status information file.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscplp

SEE ALSO `echo(1)`, `lpq(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `lpsched(1M)`, `lpshut(1M)`, `printers.conf(4)`, `attributes(5)`

DIAGNOSTICS Ambiguous command
Indicates that the `lpc` command or abbreviation matches more than one command.

?Invalid command
Indicates that the `lpc` command or abbreviation is not recognized.

?Privileged command
Indicates that the `lpc` command or abbreviation can be executed only by a super-user.

`lpc: printer` : unknown printer to the print service
Indicates that *printer* does not exist in the LP database. Check that *printer* was correctly specified. Use `lpstat -p` or the `status` command (see `lpstat(1)` or `USAGE`) to check the status of printers.

lpc(1B)

lpc: error on opening queue to spooler

Indicates that the connection to lpsched failed. Usually means that the printer server has died or is hung. Use /usr/lib/lp/lpsched to check if the printer spooler daemon is running.

lpc: Can't send message to LP print service

lpc: Can't receive message from LP print service

Indicates that the LP print service stopped. Contact the LP administrator.

lpc: Received unexpected message from LP print service

Indicates a problem with the software. Contact the LP administrator.

NAME	lpq – display the content of a print queue
SYNOPSIS	<code>/usr/ucb/lpq [-P <i>destination</i>] [-l] [+ [<i>interval</i>]] [<i>request-ID</i>...] [<i>user</i>...]</code>
DESCRIPTION	<p>The <code>lpq</code> utility displays the information about the contents of a print queue. A print queue is comprised of print requests that are waiting in the process of being printed.</p> <p><code>lpq</code> displays the following information to the standard output:</p> <ul style="list-style-type: none"> ■ the username of the person associated with a print request, ■ the position of a print request in the print queue, ■ the name of file or files comprising a print request, ■ the job number of a print request, and ■ the size of the file requested by a print request. File size is reported in bytes. <p>Normally, only as much information as will fit on one line is displayed. If the name of the input file associated with a print request is not available, the input file field indicates the standard input.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-P <i>destination</i></code> Displays information about printer or class of printers (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic, POSIX-style (<code>server:destination</code>), or Federated Naming Service (FNS) (<code>../service/printer/..</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p><code>-l</code> Displays information in long format. Long format includes the name of the host from which a print request originated in the display.</p> <p><code>+ [<i>interval</i>]</code> Displays information at specific time intervals. Stops displaying information when the print queue is empty. Clears the screen before reporting displaying the print queue. Specify <i>interval</i> as the number of seconds between displays. If <i>interval</i> is not specified only executes once.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>request-ID</i> The job number associated with a print request.</p> <p><i>user</i> The name of the user about whose jobs <code>lpq</code> reports information. Specify <i>user</i> as a valid username.</p>
EXIT STATUS	The following exit values are returned:

lpq(1B)

0 Successful completion.
non-zero An error occurred.

FILES /var/spool/print/[cd]f*
Spooling directory and request files for jobs awaiting transfer.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscplp

SEE ALSO `lp(1)`, `lpc(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `lpadmin(1M)`, `nsswitch.conf(4)`, `printers(4)`, `printers.conf(4)`, `attributes(5)`, `standards(5)`

NAME	lpr – submit print requests
SYNOPSIS	<code>/usr/ucb/lpr [-P <i>destination</i>] [-# <i>number</i>] [-C <i>class</i>] [-J <i>job</i>] [-T <i>title</i>] [-i [<i>indent</i>]] [-1 -2 -3 -4 <i>font</i>] [-w <i>cols</i>] [-m] [-h] [-s] [-filter_option] [<i>file...</i>]</code>
DESCRIPTION	<p>The lpr utility submits print requests to a destination. lpr prints files (<i>file</i>) and associated information, collectively called a <i>print request</i>. If <i>file</i> is not specified, lpr assumes the standard input.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p> <p>Print requests with more than 52 <i>files</i> specified will be truncated to 52 files. lpr displays a warning message.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -P <i>destination</i> Prints <i>file</i> on a specific printer or class of printers(see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX. -# <i>number</i> Prints a specific number of copies. Specify <i>number</i> as a positive integer. The default for <i>number</i> is 1. -C <i>class</i> Prints <i>class</i> as the job classification on the banner page of the output. Enclose <i>class</i> in double quotes if it contains blanks. If <i>class</i> is not specified, the name of the system (as returned by <code>hostname</code>) is printed as the job classification. See <code>hostname(1)</code>. -J <i>job</i> Prints <i>job</i> as the <i>job name</i> on the banner page of the output. Enclose <i>job</i> in double quotes if it contains blanks. If <i>job</i> is not specified, <i>file</i> (or in the case of multiple files, the first <i>file</i> specified on the command line) is printed as the job name on the banner page of the output. -T <i>title</i> Prints a title on the page header of the output. Enclose <i>title</i> in double quotes if it contains blanks. The -T option is ignored unless it is specified with the -p filter option. -i <i>indent</i> Indents the output a specific number of SPACE characters. Use <i>indent</i> to indicate the number of SPACE characters to be indented. Specify <i>indent</i> as a positive

lpr(1B)

	integer. If the optional argument to indent is not specified, then eight <code>SPACE</code> characters is the default. The <code>-i</code> option is ignored unless it is specified with the <code>-p</code> filter option.						
<code>-1 -2 -3 -4 font</code>	Mounts the specified font in the font position 1, 2, 3, or 4. Specify <i>font</i> as a valid font name.						
<code>-w cols</code>	Prints <i>file</i> with pages of a specific width. <i>cols</i> indicates the number of columns wide. The <code>-w</code> option is ignored unless it is specified with the <code>-p</code> filter option.						
<code>-m</code>	Sends mail after <i>file</i> has printed. See <code>mail(1)</code> . By default, no mail is sent upon normal completion of a print request.						
<code>-h</code>	Suppresses printing of the banner page of the output.						
<code>-s</code>	Uses full pathnames (as opposed to symbolic links) to <i>file</i> rather than trying to copy them. This means <i>file</i> should not be modified or removed until it has completed printing. Option <code>-s</code> only prevents copies of local files from being made on the local machine. Option <code>-s</code> only works with specified <i>files</i> . If the <code>lpr</code> command is at the end of a pipeline, <i>file</i> is copied to the spool.						
<code>- filter_option</code>	<p>Notifies the print spooler that <i>file</i> is not a standard text file. Enables the spooling daemon to use the appropriate filters to print <i>file</i>.</p> <p><i>filter_options</i> offer a standard user interface. All filter options may not be available for, or applicable to, all printers.</p> <p>Specify <i>filter_option</i> as a single character.</p> <p>If <i>filter_option</i> is not specified and the printer can interpret PostScript®, inserting ‘%!’ as the first two characters of <i>file</i> causes <i>file</i> to be interpreted as PostScript.</p> <p>The following filter options are supported:</p> <table><tr><td><code>p</code></td><td>Use <code>pr</code> to format the files. See <code>pr(1)</code>.</td></tr><tr><td><code>l</code></td><td>Print control characters and suppress page breaks.</td></tr><tr><td><code>t</code></td><td><i>file</i> contains <code>troff</code> (cat phototypesetter) binary data.</td></tr></table>	<code>p</code>	Use <code>pr</code> to format the files. See <code>pr(1)</code> .	<code>l</code>	Print control characters and suppress page breaks.	<code>t</code>	<i>file</i> contains <code>troff</code> (cat phototypesetter) binary data.
<code>p</code>	Use <code>pr</code> to format the files. See <code>pr(1)</code> .						
<code>l</code>	Print control characters and suppress page breaks.						
<code>t</code>	<i>file</i> contains <code>troff</code> (cat phototypesetter) binary data.						

n	<i>file</i> contains <code>ditroff</code> data from device independent troff.
d	<i>file</i> contains <code>tex</code> data in DVI format from Stanford.
g	<i>file</i> contains standard plot data produced by <code>plot(1B)</code> routines.
v	<i>file</i> contains a raster image. <i>printer</i> must support an appropriate imaging model such as PostScript in order to print the image.
c	<i>file</i> contains data produced by <i>cifplot</i> .
f	Interprets the first character of each line as a standard FORTRAN carriage control character.

OPERANDS The following operand is supported:

file The name of the file to be printed. Specify *file* as a pathname. If *file* is not specified, `lpr` uses the standard input.

USAGE See `largefile(5)` for the description of the behavior of `lpr` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXIT STATUS The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

FILES

<code>/var/spool/print/.seq</code>	File containing the sequence numbers for job ID assignment.
<code>/var/spool/print/[cd]f*</code>	Spooling directories and files.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscplp
CSI	Enabled (see NOTES)

SEE ALSO `hostname(1)`, `lp(1)`, `lpc(1B)`, `lpq(1B)`, `lprm(1B)`, `lpstat(1)`, `mail(1)`, `plot(1B)`, `pr(1)`, `troff(1)`, `lpadmin(1M)`, `nsswitch.conf(4)`, `printers(4)`, `printers.conf(4)`, `attributes(5)`, `largefile(5)`, `standards(5)`

DIAGNOSTICS `lpr: destination | : unknown destination`
destination was not found in the LP configuration database. Usually this is a typing mistake; however, it may indicate that the *destination* does not exist on the system.

lpr(1B)

Use `lpstat -p` to display information about the status of the print service.

NOTES `lpr` is CSI-enabled except for the *printer* name.

Print jobs are assumed to contain one type of data. That type of data is either specified on the command line or autodetected (simple, PostScript) based on the contents of the first file in the job.

NAME	lprm – remove print requests from the print queue
SYNOPSIS	<code>/usr/ucb/lprm [-P <i>destination</i>] [-] [<i>request-ID</i>...] [<i>user</i>...]</code>
DESCRIPTION	<p>The lprm utility removes print requests (<i>request-ID</i>) from the print queue.</p> <p>Without arguments, lprm deletes the current print request. lprm reports the name of the file associated with print requests that it removes. lprm is silent if there are no applicable print requests to remove.</p> <p>Users can only remove print requests associated with their user name. See NOTES. If a super-user executes lprm and specifies the <i>user</i> operand, lprm removes all print requests belonging to the specified user.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-P <i>destination</i></code> The name of the printer or class of printers (see <code>lpadmin(1M)</code>) from which to remove print requests. Specify destination using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX. <code>-</code> If a user specifies this option, removes all print requests owned by that user. If a super-user specifies this option, removes all requests in the print queue. Job ownership is determined by the user’s login name and host name on the machine from which lpr was executed. See NOTES.
OPERANDS	<p>The following operands are supported.</p> <ul style="list-style-type: none"> <i>user</i> Removes print requests associated with a specific user. Specify <i>user</i> as a valid user name. This option can only be used by a super-user. <i>request-ID</i> Removes a specific print request. Specify <i>request-ID</i> as the job number (JOB) associated with a print request and reported by lpr. See <code>lpq(1B)</code>.
EXAMPLES	<p>EXAMPLE 1 Removing a print request</p> <p>The following example removes request-ID 385 from destination <code>killtree</code>:</p> <pre>example% lprm -P killtree 385</pre>
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 Successful completion.

lprm(1B)

non-zero An error occurred.

FILES /var/spool/print/[cd]f* Spooling directories and files.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscplp

SEE ALSO `lp(1)`, `lpc(1B)`, `lpq(1B)`, `lpr(1B)`, `lpstat(1)`, `lpadmin(1M)`, `nsswitch.conf(4)`, `printers(4)`, `printers.conf(4)`, `attributes(5)`, `standards(5)`

NOTES Users can only remove print requests associated with their user name. By default, users can only remove print requests on the host from which the print request was submitted. If a super-user has set `user-equivalence=true` in `/etc/printers.conf` on the print server, users can remove print requests associated with their user name on any host. Super-users can remove print requests on the host from which the print request was submitted. Super-users can also remove print requests from the print server.

NAME	lpstat – print information about the status of the print service
SYNOPSIS	lpstat [-d] [-r] [-R] [-s] [-t] [-a <i>list</i>] [-c <i>list</i>] [-f <i>list</i>] [-l] [-o <i>list</i>] [-p <i>list</i>] [-D] [-l] [-S <i>list</i>] [-l] [-u <i>login-ID -list</i>] [-v <i>list</i>]
DESCRIPTION	<p>The lpstat utility displays information about the current status of the LP print service to standard output.</p> <p>If no options are given, lpstat prints the status of all the user’s print requests made by lp. (see lp(1)). Any arguments that are not <i>options</i> are assumed to be <i>request-IDs</i> as returned by lp. The lpstat command prints the status of such requests. <i>options</i> may appear in any order and may be repeated and intermixed with other arguments. Some key letters may be followed by an optional <i>list</i> that can be in one of two forms: a list of items separated from one another by a comma, or a list of items separated from one another by spaces enclosed in quotes. For example:</p> <pre>example% lpstat -u "user1 user2 user3"</pre> <p>Specifying all after any key letter that takes <i>list</i> as an argument causes all information relevant to the key letter to be printed. For example, the command:</p> <pre>example% lpstat -o all</pre> <p>prints the status of all output requests.</p> <p>The omission of a <i>list</i> following such key letters causes all information relevant to the key letter to be printed. For example, the command:</p> <pre>example% lpstat -o</pre> <p>prints the status of all output requests.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See nsswitch.conf(4), printers(4), and printers.conf(4) for details.</p>
OPTIONS	<p>The following options are supported on all platforms.</p> <p>-d Prints the default destination for output requests.</p> <p>-o <i>list</i> Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and request-IDs. The key letter -o may be omitted. Specify printer and class names using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<i>../service/printer/..</i>) names. See printers.conf(4) for information regarding the naming conventions for atomic and FNS names, and standards(5) for information regarding POSIX.</p>

lpstat(1)

-r	Prints the status of the LP request scheduler.
-R	Prints a number showing the position of each request in the print queue.
-s	Prints a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms currently mounted, and a list of all recognized character sets and print wheels.
-t	Prints all status information. This includes all the information obtained with the -s option, plus the acceptance and idle/busy status of all printers.
-u [<i>login-ID-list</i>]	Prints the status of output requests for users. The <i>login-ID-list</i> argument may include any or all of the following constructs: <i>login-ID</i> a user on any system <i>system_name !login-ID</i> a user on system <i>system_name</i> <i>system_name !all</i> all users on system <i>system_name</i> <i>all !login-ID</i> a user on all systems <i>all</i> all users on all systems
-v [<i>list</i>]	Prints the names of printers and the path names of the devices associated with them or remote system names for network printers. <i>list</i> is a list of printer names.
The following options return accurate results only if they are issued from a Solaris 2.6 Operating Environment or compatible version of the LP print server.	
-a [<i>list</i>]	Reports whether print destinations are accepting requests. <i>list</i> is a list of intermixed printer names and class names.
-c [<i>list</i>]	Prints name of all classes and their members. <i>list</i> is a list of class names.
-f [<i>list</i>] [-1]	Prints a verification that the forms in <i>list</i> are recognized by the LP print service. <i>list</i> is a list of forms; the default is <i>all</i> . The -1 option will list the form descriptions.
-p [<i>list</i>] [-D] [-1]	Prints the status of printers. <i>list</i> is a list of printer names. If the -D option is given, a brief description is

	printed for each printer in <i>list</i> . If the <i>-l</i> option is given and the printer is on the local machine, a full description of each printer's configuration is returned, including the form mounted, the acceptable content and printer types, a printer description, and the interface used.
<i>-s</i> [<i>list</i>] [<i>-l</i>]	Prints a verification that the character sets or the print wheels specified in <i>list</i> are recognized by the LP print service. Items in <i>list</i> can be character sets or print wheels; the default for the list is <i>all</i> . If the <i>-l</i> option is given, each line is appended by a list of printers that can handle the print wheel or character set. The list also shows whether the print wheel or character set is mounted, or specifies the built-in character set into which it maps.
<i>-d</i>	Prints the default destination for output requests.
<i>-o</i> [<i>list</i>]	Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and <i>request-IDs</i> . The key letter <i>-o</i> may be omitted.
<i>-r</i>	Prints the status of the LP request scheduler.
<i>-R</i>	Prints a number showing the position of each request in the print queue.
<i>-s</i>	Prints a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms currently mounted, and a list of all recognized character sets and print wheels.
<i>-t</i>	Prints all status information. This includes all the information obtained with the <i>-s</i> option, plus the acceptance and idle/busy status of all printers.
<i>-u</i> [<i>login-ID-list</i>]	Prints the status of output requests for users. The <i>login-ID-list</i> argument may include any or all of the following constructs: <i>login-ID</i> a user on any system <i>system_name</i> ! <i>login-ID</i> a user on system <i>system_name</i> <i>system_name</i> ! <i>all</i> all users on system <i>system_name</i> <i>all</i> ! <i>login-ID</i> a user on all systems

lpstat(1)

all
all users on all systems

-v [*list*] Prints the names of printers and the path names of the devices associated with them or remote system names for network printers. *list* is a list of printer names.

EXIT STATUS The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

FILES

/var/spool/print/*	LP print queue.
\$HOME/.printers	User-configurable printer database.
/etc/printers.conf	System configuration database.
printers.conf.byname	NIS version of /etc/printers.conf.

NAME	lptest – generate line printer ripple pattern					
SYNOPSIS	<code>/usr/ucb/lptest</code> [<i>length</i> [<i>count</i>]]					
DESCRIPTION	<p>The <code>lptest</code> utility writes the traditional <i>ripple test</i> pattern to the standard output. In 96 lines, the ripple test pattern prints all 96 printable ASCII characters in each position. The ripple test pattern was originally created to test printers. It is also useful for testing terminals, driving terminal ports, debugging, and performing tasks that require a quick supply of random data.</p> <p>This command is obsolete.</p>					
OPTIONS	<i>length</i>	Specifies the length of the output line in characters. 79 characters is the default.				
	<i>count</i>	Specifies the number of output lines. 200 lines is the default. If <i>count</i> is specified, <i>length</i> must also be specified.				
EXIT STATUS	The following exit values are returned:					
	0	Successful completion.				
	non-zero	An error occurred.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ls(1)

NAME	ls – list contents of directory
SYNOPSIS	<pre>/usr/bin/ls [-aAbcCdFghilLmnopqrRstux1@] [file...] /usr/xpg4/bin/ls [-aAbcCdFghilLmnopqrRstux1@] [file...]</pre>
DESCRIPTION	<p>For each <i>file</i> that is a directory, <code>ls</code> lists the contents of the directory. For each <i>file</i> that is an ordinary file, <code>ls</code> repeats its name and any other information requested. The output is sorted alphabetically by default. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments appear before directories and their contents.</p> <p>There are three major listing formats. The default format for output directed to a terminal is multi-column with entries sorted down the columns. The <code>-1</code> option allows single column output and <code>-m</code> enables stream output format. In order to determine output formats for the <code>-C</code>, <code>-x</code>, and <code>-m</code> options, <code>ls</code> uses an environment variable, <code>COLUMNS</code>, to determine the number of character positions available on one output line. If this variable is not set, the <code>terminfo(4)</code> database is used to determine the number of columns, based on the environment variable, <code>TERM</code>. If this information cannot be obtained, 80 columns are assumed.</p> <p>The mode printed under the <code>-l</code> option consists of ten characters. The first character may be one of the following:</p> <ul style="list-style-type: none">d The entry is a directory.D The entry is a door.l The entry is a symbolic link.b The entry is a block special file.c The entry is a character special file.p The entry is a FIFO (or “named pipe”) special file.s The entry is an AF_UNIX address family socket.– The entry is an ordinary file. <p>The next 9 characters are interpreted as three sets of three bits each. The first set refers to the owner’s permissions; the next to permissions of others in the user-group of the file; and the last to all others. Within each set, the three characters indicate permission to read, to write, and to execute the file as a program, respectively. For a directory, “execute” permission is interpreted to mean permission to search the directory for a specified file. The character after permissions is ACL indication. A plus sign is displayed if there is an ACL associated with the file. Nothing is displayed if there are just permissions.</p> <p><code>ls -l</code> (the long list) prints its output as follows for the POSIX locale:</p> <pre>-rwxrwxrwx+ 1 smith dev 10876 May 16 9:42 part2</pre>

Reading from right to left, you see that the current directory holds one file, named `part2`. Next, the last time that file's contents were modified was 9:42 A.M. on May 16. The file contains 10,876 characters, or bytes. The owner of the file, or the user, belongs to the group `dev` (perhaps indicating "development"), and his or her login name is `smith`. The number, in this case 1, indicates the number of links to file `part2` (see `cp(1)`). The plus sign indicates that there is an ACL associated with the file. *Note:* If the `-@` option has been specified, the presence of extended attributes will supersede the presence of an ACL and the plus sign will be replaced with an 'at' sign (`@`). Finally, the dash and letters tell you that user, group, and others have permissions to read, write, and execute `part2`.

The execute (`x`) symbol here occupies the third position of the three-character sequence. A `-` in the third position would have indicated a denial of execution permissions.

The permissions are indicated as follows:

<code>r</code>	The file is readable.
<code>w</code>	The file is writable.
<code>x</code>	The file is executable.
<code>-</code>	The indicated permission is <i>not</i> granted.
<code>s</code>	The set-user-ID or set-group-ID bit is on, and the corresponding user or group execution bit is also on.
<code>S</code>	Undefined bit-state (the set-user-ID bit is on and the user execution bit is off).
<code>t</code>	The 1000 (octal) bit, or sticky bit, is on (see <code>chmod(1)</code>), and execution is on.
<code>T</code>	The 1000 bit is turned on, and execution is off (undefined bit-state).
<code>/usr/bin/ls</code> 1	Mandatory locking occurs during access (the set-group-ID bit is on and the group execution bit is off).
<code>/usr/xpg4/bin/ls</code> L	Mandatory locking occurs during access (the set-group-ID bit is on and the group execution bit is off).

For user and group permissions, the third position is sometimes occupied by a character other than `x` or `-`. `s` also may occupy this position, referring to the state of the set-ID bit, whether it be the user's or the group's. The ability to assume the same ID as the user during execution is, for example, used during login when you begin as root but need to assume the identity of the user you login as.

In the case of the sequence of group permissions, `l` may occupy the third position. `l` refers to mandatory file and record locking. This permission describes a file's ability to allow other files to lock its reading or writing permissions during access.

For others permissions, the third position may be occupied by `t` or `T`. These refer to the state of the sticky bit and execution permissions.

ls(1)

OPTIONS

The following options are supported:

- a Lists all entries, including those that begin with a dot (.), which are normally not listed.
- A Lists all entries, including those that begin with a dot (.), with the exception of the working directory (.) and the parent directory (..).
- b Forces printing of non-printable characters to be in the octal \ddd notation.
- c Uses time of last modification of the i-node (file created, mode changed, and so forth) for sorting (-t) or printing (-l or -n).
- C Multi-column output with entries sorted down the columns. This is the default output format.
- d If an argument is a directory, lists only its name (not its contents). Often used with -l to get the status of a directory.
- f Forces each argument to be interpreted as a directory and list the name found in each slot. This option turns off -l, -t, -s, and -r, and turns on -a. The order is the order in which entries appear in the directory.
- F Marks directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (*), FIFOs with a trailing vertical bar (|), symbolic links with a trailing 'at' sign (@), and AF_UNIX address family sockets with a trailing equals sign (=).
- g The same as -l, except that the owner is not printed.
- h All sizes are scaled to a human readable format, for example, 14K, 234M, 2.7G, or 3.0T. Scaling is done by repetitively dividing by 1024.
- i For each file, prints the i-node number in the first column of the report.
- l Lists in long format, giving mode, ACL indication, number of links, owner, group, size in bytes, and time of last modification for each file (see above). If the file is a special file, the size field instead contains the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format 'month date year' for the POSIX locale. When the LC_TIME locale category is not set to the POSIX locale, a different format of the time field may be used. Files modified within six months show 'month date time'. If the file is a symbolic link, the filename is printed followed by "→" and the path name of the referenced file.
- L If an argument is a symbolic link, lists the file or directory the link references rather than the link itself.
- m Streams output format. Files are listed across the page, separated by commas.
- n The same as -l, except that the owner's UID and group's GID numbers are printed, rather than the associated character strings.
- o The same as -l, except that the group is not printed.

-p	Puts a slash (/) after each filename if the file is a directory.
-q	Forces printing of non-printable characters in file names as the character question mark (?).
-r	Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
-R	Recursively lists subdirectories encountered.
-s	Gives size in blocks, including indirect blocks, for each entry.
-t	Sorts by time stamp (latest first) instead of by name. The default is the last modification time. (See -u and -c.)
-u	Uses time of last access instead of last modification for sorting (with the -t option) or printing (with the -l option).
-@	The same as -l, except that extended attribute information will supersede ACL information. An @ is displayed after the file permission bits for files that have extended attributes.
-x	Multi-column output with entries sorted across rather than down the page.
-l	Prints one entry per line of output.

/usr/bin/ls Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (ell), -m and -l (ell), -x and -l (ell), -@ and -l (ell). The -l option overrides the other option specified in each pair.

/usr/xpg4/bin/ls Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (ell), -m and -l (ell), -x and -l (ell), -@ and -l (ell). The last option specified in each pair determines the output format.

OPERANDS The following operand is supported:

file A path name of a file to be written. If the file specified is not found, a diagnostic message will be output on standard error.

USAGE See `largefile(5)` for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** File permissions

An example of a file's permissions is:

```
-rwxr- -r- -
```

This describes a file that is readable, writable, and executable by the user and readable by the group and others.

Another example of a file's permissions is:

```
-rwsr-xr-x
```

ls(1)

EXAMPLE 1 File permissions (Continued)

This describes a file that is readable, writable, and executable by the user, readable and executable by the group and others, and allows its user-ID to be assumed, during execution, by the user presently executing it.

Another example of a file's permissions is:

```
-rw-rw1- - -
```

This describes a file that is readable and writable only by the user and the group and can be locked during access.

EXAMPLE 2 Printing the names of all files

This command prints the names of all files in the current directory, including those that begin with a dot (.), which normally do not print:

```
example% ls -a
```

EXAMPLE 3 Providing file information

Another example of a command line is:

```
example% ls -aisn
```

This command provides information on all files, including those that begin with a dot (a), the i-number—the memory address of the i-node associated with the file—printed in the left-hand column (i); the size (in blocks) of the files, printed in the column to the right of the i-numbers (s); finally, the report is displayed in the numeric version of the long list, printing the UID (instead of user name) and GID (instead of group name) numbers associated with the files.

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

**ENVIRONMENT
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `ls`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLSPATH`, and `TZ`.

COLUMNS Determines the user's preferred column position width for writing multiple text-column output. If this variable contains a string representing a decimal integer, the `ls` utility calculates how many path name text columns to write (see `-C`) based on the width provided. If `COLUMNS` is not set or is invalid, 80 is used. The column width chosen to write the names of files in any given directory will be constant. File names will not be truncated to fit into the multiple text-column output.

EXIT STATUS 0 All information was written successfully.
 >0 An error occurred.

FILES /etc/group group IDs for `ls -l` and `ls -g`
 /etc/passwd user IDs for `ls -l` and `ls -o`
 /usr/share/lib/terminfo/?/* terminal information database

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/ls`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

`/usr/xpg4/bin/ls`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled
Interface Stability	Standard

SEE ALSO `chmod(1)`, `cp(1)`, `setfacl(1)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `fsattr(5)`, `largefile(5)`, `standards(5)`

NOTES Unprintable characters in file names may confuse the columnar output options.

The total block count will be incorrect if there are hard links among the files.

The sort order of `ls` output is affected by the locale and can be overridden by the `LC_COLLATE` environment variable. For example, if `LC_COLLATE` equals `C`, dot files appear first, followed by names beginning with upper-case letters, then followed by names beginning with lower-case letters. But if `LC_COLLATE` equals `en_US.ISO8859-1`, then leading dots as well as case are ignored in determining the sort order.

ls(1B)

NAME	ls – list the contents of a directory
SYNOPSIS	<code>/usr/ucb/ls [-aAcCdFgILqrRstu1] file...</code>
DESCRIPTION	<p>For each <i>filename</i> that is a directory, <code>ls</code> lists the contents of the directory; for each <i>filename</i> that is a file, <code>ls</code> repeats its name and any other information requested. By default, the output is sorted alphabetically. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments are processed before directories and their contents.</p>
Permissions Field	<p>The mode printed under the <code>-l</code> option contains 10 characters interpreted as follows. If the first character is:</p> <ul style="list-style-type: none"><code>d</code> Entry is a directory.<code>D</code> Entry is a door.<code>b</code> Entry is a block-type special file.<code>c</code> Entry is a character-type special file.<code>l</code> Entry is a symbolic link.<code>p</code> Entry is a FIFO (also known as “named pipe”) special file.<code>s</code> Entry is an AF_UNIX address family socket.<code>-</code> Entry is a plain file. <p>The next 9 characters are interpreted as three sets of three bits each. The first set refers to owner permissions; the next refers to permissions to others in the same user-group; and the last refers to all others. Within each set, the three characters indicate permission respectively to read, to write, or to execute the file as a program. For a directory, “execute” permission is interpreted to mean permission to search the directory. The permissions are indicated as follows:</p> <ul style="list-style-type: none"><code>r</code> The file is readable.<code>w</code> The file is writable.<code>x</code> The file is executable.<code>-</code> The indicated permission is not granted. <p>The group-execute permission character is given as <code>s</code> if the file has the set-group-id bit set; likewise the owner-execute permission character is given as <code>S</code> if the file has the set-user-id bit set.</p> <p>The last character of the mode (normally <code>x</code> or <code>'-'</code>) is <code>true</code> if the 1000 bit of the mode is on. See <code>chmod(1)</code> for the meaning of this mode. The indications of set-ID and 1000 bits of the mode are capitalized (<code>S</code> and <code>T</code>, respectively) if the corresponding execute permission is <i>not</i> set.</p> <p>A plus sign (+) appended to the list of permissions indicates that an ACL is associated with the file.</p>

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

OPTIONS

The following options are supported:

- a Lists all entries; in the absence of this option, entries whose names begin with a `'.'` are *not* listed (except for the privileged user, for whom `ls` normally prints even files that begin with a `'.'`).
- A Same as `-a`, except that `'.'` and `'..'` are not listed.
- c Uses time of last edit (or last mode change) for sorting or printing.
- C Forces multi-column output, with entries sorted down the columns; for `ls`, this is the default when output is to a terminal.
- d If argument is a directory, lists only its name (not its contents); often used with `-l` to get the status of a directory.
- f Forces each argument to be interpreted as a directory and lists the name found in each slot. This option turns off `-l`, `-t`, `-s`, and `-r`, and turns on `-a`; the order is the order in which entries appear in the directory.
- F Marks directories with a trailing slash (`/`), doors with a trailing greater-than sign (`>`), executable files with a trailing asterisk (`*`), FIFOs with a trailing vertical bar (`|`), symbolic links with a trailing at-sign (`@`), and AF_UNIX address family sockets with a trailing equals sign (`=`).
- g For `ls`, shows the group ownership of the file in a long output.
- i For each file, prints the i-node number in the first column of the report.
- l Lists in long format, giving mode, ACL indication, number of links, owner, size in bytes, and time of last modification for each file. If the file is a special file the size field will instead contain the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format `'month date year'`; files modified within six months show `'month date time'`. If the file is a symbolic link, the pathname of the linked-to file is printed preceded by `'->'`.
- L If argument is a symbolic link, lists the file or directory the link references rather than the link itself.
- q Displays non-graphic characters in filenames as the character `?`; for `ls`, this is the default when output is to a terminal.
- r Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
- R Recursively lists subdirectories encountered.
- s Gives size of each file, including any indirect blocks used to map the file, in kilobytes.
- t Sorts by time modified (latest first) instead of by name.

ls(1B)

- u Uses time of last access instead of last modification for sorting (with the -t option) and/or printing (with the -l option).
- l Forces one entry per line output format; this is the default when output is not to a terminal.

OPERANDS The following operand is supported:

file A path name of a file to be listed. If the file specified is not found, a diagnostic message will be output on standard error.

USAGE See `largefile(5)` for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES `/etc/group` to get group ID for '`ls -g`'
`/etc/passwd` to get user IDs for '`ls -l`' and '`ls -o`'

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO `ls(1)`, `attributes(5)`, `largefile(5)`

NOTES NEWLINE and TAB are considered printing characters in filenames.

The output device is assumed to be 80 columns wide.

The option setting based on whether the output is a teletype is undesirable as '`ls -s`' is much different than '`ls -s | lpr`'. On the other hand, not doing this setting would make old shell scripts which used `ls` almost certain losers.

Unprintable characters in file names may confuse the columnar output options.

NAME	m4 – macro processor
SYNOPSIS	<pre> /usr/ccs/bin/m4 [-e] [-s] [-B int] [-H int] [-S int] [-T int] [-Dname [=val]] ... [-U name] ... [file...] /usr/xpg4/bin/m4 [-e] [-s] [-B int] [-H int] [-S int] [-T int] [-Dname [...=val]] [-U name] ... [file...] </pre>
DESCRIPTION	<p>The m4 utility is a macro processor intended as a front end for C, assembler, and other languages. Each of the argument files is processed in order; if there are no files, or if a file is <code>-</code>, the standard input is read. The processed text is written on the standard output.</p>
Macro Syntax	<p>Macro calls have the form:</p> <pre>name (arg1,arg2, . . . , argn)</pre> <p>The open parenthesis character (must immediately follow the name of the macro. If the name of a defined macro is not followed by a (, it is deemed to be a call of that macro with no arguments. Potential macro names consist of alphanumeric characters and underscore (<code>_</code>), where the first character is not a digit.</p> <p>Leading unquoted blanks, TABs, and NEWLINES are ignored while collecting arguments. Left and right single quotes are used to quote strings. The value of a quoted string is the string stripped of the quotes.</p>
Macro Processing	<p>When a macro name is recognized, its arguments are collected by searching for a matching right parenthesis. If fewer arguments are supplied than are in the macro definition, the trailing arguments are taken to be NULL. Macro evaluation proceeds normally during the collection of the arguments, and any commas or right parentheses that happen to turn up within the value of a nested call are as effective as those in the original input text. After argument collection, the value of the macro is pushed back onto the input stream and rescanned.</p>
OPTIONS	<p>The options and their effects are as follows:</p> <ul style="list-style-type: none"> -Bint Changes the size of the push-back and argument collection buffers from the default of 4,096. -e Operates interactively. Interrupts are ignored and the output is unbuffered. -Hint Changes the size of the symbol table hash array from the default of 199. The size should be prime. -s Enables line sync output for the C preprocessor (#line . . .) -Sint Changes the size of the call stack from the default of 100slots. Macros take three slots, and non-macro arguments take one. -Tint Changes the size of the token buffer from the default of 512bytes.

m4(1)

	To be effective, the above flags must appear before any file names and before any <code>-D</code> or <code>-U</code> flags:
	<code>-D name[=val]</code> Defines <i>name</i> to <i>val</i> or to NULL in <i>val</i> 's absence.
	<code>-Uname</code> Undefines <i>name</i> .
OPERANDS	The following operand is supported:
	<i>file</i> A path name of a text file to be processed. If no <i>file</i> is given, or if it is <code>-</code> , the standard input is read.
USAGE	The <code>m4</code> utility makes available the following built-in macros. These macros may be redefined, but once this is done the original meaning is lost. Their values are NULL unless otherwise stated.
	<code>changequote</code> Change quote symbols to the first and second arguments. The symbols may be up to five characters long. <code>changequote</code> without arguments restores the original values (that is, <code>' '</code>).
	<code>changecom</code> Change left and right comment markers from the default <code>#</code> and <code>NEWLINE</code> . With no arguments, the comment mechanism is effectively disabled. With one argument, the left marker becomes the argument and the right marker becomes <code>NEWLINE</code> . With two arguments, both markers are affected. Comment markers may be up to five characters long.
	<code>decr</code> Returns the value of its argument decremented by 1.
	<code>define</code> The second argument is installed as the value of the macro whose name is the first argument. Each occurrence of <code>\$n</code> in the replacement text, where <i>n</i> is a digit, is replaced by the <i>n</i> -th argument. Argument 0 is the name of the macro; missing arguments are replaced by the null string; <code>\$#</code> is replaced by the number of arguments; <code>\$*</code> is replaced by a list of all the arguments separated by commas; <code>\$@</code> is like <code>\$*</code> , but each argument is quoted (with the current quotes).
	<code>defn</code> Returns the quoted definition of its argument(s). It is useful for renaming macros, especially built-ins.
	<code>divert</code> <code>m4</code> maintains 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order; initially stream 0 is the current stream. The <code>divert</code> macro changes the current output stream to its (digit-string) argument. Output diverted to a stream other than 0 through 9 is discarded.
	<code>divnum</code> Returns the value of the current output stream.
	<code>dn1</code> Reads and discards characters up to and including the next <code>NEWLINE</code> .

	<code>dumpdef</code>	Prints current names and definitions, for the named items, or for all if no arguments are given.
	<code>errprint</code>	Prints its argument on the diagnostic output file.
<code>/usr/ccs/bin/m4</code>	<code>eval</code>	Evaluates its argument as an arithmetic expression, using 32-bit signed-integer arithmetic. The following operators are supported: parentheses, unary <code>-</code> , unary <code>+</code> , <code>!</code> , <code>~</code> , <code>*</code> , <code>/</code> , <code>%</code> , <code>+</code> , <code>-</code> , relationals, bitwise <code>&</code> , <code> </code> , <code>&&</code> , and <code> </code> . Octal and hex numbers may be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.
<code>/usr/xpg4/bin/m4</code>	<code>eval</code>	Evaluates its argument as an arithmetic expression, using 32-bit signed-integer arithmetic. The following operators are supported: parentheses, unary <code>-</code> , unary <code>+</code> , <code>!</code> , <code>~</code> , <code>*</code> , <code>/</code> , <code>%</code> , <code>+</code> , <code>-</code> , <code><<</code> , <code>>></code> , relationals, bitwise <code>&</code> , <code> </code> , <code>&&</code> , and <code> </code> . Precedence and associativity are as in C. Octal and hex numbers may also be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.
	<code>ifdef</code>	If the first argument is defined, the value is the second argument, otherwise the third. If there is no third argument, the value is <code>NULL</code> . The word <code>unix</code> is predefined.
	<code>ifelse</code>	This macro has three or more arguments. If the first argument is the same string as the second, then the value is the third argument. If not, and if there are more than four arguments, the process is repeated with arguments 4, 5, 6 and 7. Otherwise, the value is either the fourth string, or, if it is not present, <code>NULL</code> .
	<code>include</code>	Returns the contents of the file named in the argument.
	<code>incr</code>	Returns the value of its argument incremented by 1. The value of the argument is calculated by interpreting an initial digit-string as a decimal number.
	<code>index</code>	Returns the position in its first argument where the second argument begins (zero origin), or <code>-1</code> if the second argument does not occur.
	<code>len</code>	Returns the number of characters in its argument.
	<code>m4exit</code>	This macro causes immediate exit from m4. Argument 1, if given, is the exit code; the default is 0.
	<code>m4wrap</code>	Argument 1 will be pushed back at final EOF. Example: <code>m4wrap(`cleanup() `)</code>
	<code>maketemp</code>	Fills in a string of "x" characters in its argument with the current process ID.

m4(1)

<code>popdef</code>	Removes current definition of its argument(s), exposing the previous one, if any.
<code>pushdef</code>	Like <code>define</code> , but saves any previous definition.
<code>shift</code>	Returns all but its first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will subsequently be performed.
<code>sinclude</code>	This macro is identical to <code>include</code> , except that it says nothing if the file is inaccessible.
<code>substr</code>	Returns a substring of its first argument. The second argument is a zero origin number selecting the first character; the third argument indicates the length of the substring. A missing third argument is taken to be large enough to extend to the end of the first string.
<code>syscmd</code>	This macro executes the command given in the first argument. No value is returned.
<code>sysval</code>	This macro is the return code from the last call to <code>syscmd</code> .
<code>translit</code>	Transliterates the characters in its first argument from the set given by the second argument to the set given by the third. No abbreviations are permitted.
<code>traceon</code>	This macro with no arguments, turns on tracing for all macros (including built-ins). Otherwise, turns on tracing for named macros.
<code>traceoff</code>	Turns off trace globally and for any macros specified. Macros specifically traced by <code>traceon</code> can be untraced only by specific calls to <code>traceoff</code> .
<code>undefine</code>	Removes the definition of the macro named in its argument.
<code>undivert</code>	This macro causes immediate output of text from diversions named as arguments, or all diversions if no argument. Text may be undiverted into another diversion. Undiverting discards the diverted text.

EXAMPLES

EXAMPLE 1 Examples of m4 files

An example of a single `m4` input file capable of generating two output files follows. The file `file1.m4` could contain lines such as:

```
if(VER, 1, do_something)
if(VER, 2, do_something)
```

The makefile for the program might include:

```
file1.1.c :    file1.m4
              m4 -D VER=1 file1.m4 > file1.1.c
              ...
file1.2.c :    file1.m4
```

EXAMPLE 1 Examples of m4 files (Continued)

```
m4 -D VER=2 file1.m4 > file1.2.c
...
```

The -U option can be used to undefine VER. If file1.m4 contains:

```
if (VER, 1, do_something)
if (VER, 2, do_something)
ifndef (VER, do_something)
```

then the makefile would contain:

```
file1.0.c :    file1.m4
              m4 -U VER file1.m4 > file1.0.c
              ...
file1.1.c :    file1.m4
              m4 -D VER=1 file1.m4 > file1.1.c
              ...
file1.2.c :    file1.m4
              m4 -D VER=2 file1.m4 > file1.2.c
              ...
```

ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of m4: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

```
0          Successful completion.
>0        An error occurred
```

If the `m4exit` macro is used, the exit value can be specified by the input file.

mach(1)

NAME mach – display the processor type of the current host

SYNOPSIS **mach**

DESCRIPTION The mach command displays the processor-type of the current host.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `arch(1)`, `uname(1)`, `attributes(5)`

NOTES `mach` and `uname -p` return equivalent values; therefore, Independent Software Vendors (ISV) and others who need to ascertain processor type are encouraged to use `uname` with the `-p` option instead of the `mach` command. The `mach` command is provided for compatibility with previous releases, but generally its use is discouraged.

machid(1)

NAME	machid, sun, iAPX286, i286, i386, i486, i860, pdp11, sparc, u3b, u3b2, u3b5, u3b15, vax, u370 – get processor type truth value																						
SYNOPSIS	sun iAPX286 i386 pdp11 sparc u3b u3b2 u3b5 u3b15 vax u370

NOTES The machid family of commands is obsolete. Use `uname -p` and `uname -m` instead.

NAME	madv.so.1 – madv library
SYNOPSIS	<code>/usr/lib/madv.so.1</code>
DESCRIPTION	<p>The <code>madv.so.1</code> shared object provides a means by which the VM advice can be selectively configured for a launched process (or processes) and its descendants. To enable <code>madv.so.1</code>, the following string needs to be present in the environment (see <code>ld.so.1(1)</code>) along with one or more MADV environment variables:</p> <pre>LD_PRELOAD=\$LD_PRELOAD:madv.so.1</pre>
ENVIRONMENT VARIABLES	<p>If the <code>madv.so.1</code> shared object is specified in the <code>LD_PRELOAD</code> list, the following environment variables are read by the <code>madv</code> shared object to determine to which created process(es) to apply the specified advice.</p> <p><code>MADV=advice</code></p> <p><code>MADV</code> specifies the VM advice to use for all heap, shared memory, and <code>mmap</code> regions in the process address space. This advice is applied to all created processes.</p> <p>Values for <i>advice</i> correspond to values in <code><sys/mman.h></code> used in <code>madvise(3C)</code> to specify memory access patterns:</p> <ul style="list-style-type: none"> normal random sequential access_lwp access_many access_default <p><code>MADVCFGFILE=config-file</code></p> <p><i>config-file</i> is a text file which contains one or more <code>madv</code> configuration entries of the form:</p> <pre>exec-name exec-args:advice-opts</pre> <p>Advice specified in <i>config-file</i> takes precedence over that specified by the <code>MADV</code> environment variable. When <code>MADVCFGFILE</code> is not set, advice is taken from file <code>/etc/madv.conf</code> if it exists.</p> <p><i>exec-name</i> specifies the name of an application or executable. The corresponding advice is set for newly created processes (see <code>getexecname(3C)</code>) that match the first <i>exec-name</i> found in the file.</p> <p><i>exec-name</i> can be a full pathname, a base name, or a pattern string. See <code>File Name Generation</code> in <code>sh(1)</code> for a discussion of pattern matching.</p> <p><i>exec-args</i> is an optionally specified pattern string to match against arguments. Advice is set only if <i>exec-args</i> is not specified or occurs within the arguments to <i>exec-name</i>.</p>

madv.so.1(1)

advice-opts is a comma-separated list specifying the advice for various memory region(s):

madv=advice Applies to all heap, shared memory, and mmap regions in the process address space.

heap=advice The heap is defined to be the brk area (see `brk(2)`). Applies to the existing heap and for any additional heap memory allocated in the future.

shm=advice

ism=advice

dism=advice

Shared memory segments (see `shmat(2)`) attached using any flags, flag `SHM_SHARE_MMU`, or flag `SHM_PAGEABLE` respectively. Options *ism* and *dism* take precedence over option *shm*.

map=advice

mapshared=advice

mappprivate=advice

mapanon=advice

Mappings established through `mmap(2)` using any flags, flag `MAP_SHARED`, flag `MAP_PRIVATE`, or flag `MAP_ANON`, respectively. Options *mapshared*, *mappprivate*, and *mapanon* take precedence over option *map*. Option *mapanon* takes precedence over *mapshared* and *mappprivate*.

MADVERRFILE=pathname

By default, error messages are logged via `syslog(3C)` using level `LOG_ERR` and facility `LOG_USER`. If *MADVERRFILE* contains a valid *pathname* (such as `/dev/stderr`), error messages will be logged there instead.

EXAMPLES

EXAMPLE 1 Applying advice to all ISM segments

The following configuration applies advice to all ISM segments for application `/usr/bin/foo`:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
/usr/bin/foo:ism=access_lwp
```

EXAMPLE 2 Setting advice for all applications with exception

The following configuration sets advice for all applications with the exception of `ls`.

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADV=access_many
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADV MADVCFGFILE
example$ cat $MADVCFGFILE
ls:
```

EXAMPLE 3 Precedence rules (continuation from Example 2)

Because MADVCFGFILE takes precedence over MADV, specifying '*' (pattern match all) for the *exec-name* of the last madv configuration entry would be equivalent to setting MADV. The following is equivalent to example 2:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
ls:
*:madv=access_many
```

EXAMPLE 4 Applying advice for different regions

The following configuration applies one type of advice for mmap regions and different advice for heap and shared memory regions for a select set of applications with exec names that begin with foo:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
foo*:madv=access_many,heap=sequential,shm=access_lwp
```

EXAMPLE 5 Applying advice selectively

The following configuration applies advice for the heap of applications beginning with ora that have ora1 as an argument:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
ora* ora1:heap=access_many
```

FILES /etc/madv.conf Configuration file

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu (32-bit)
	SUNWesxu (64-bit)
Interface Stability	Unstable

SEE ALSO cat(1), ld.so.1(1), proc(1), sh(1), brk(2), exec(2), fork(2), mmap(2), memcntl(2), shmat(2), getexecname(3C), madvise(3C), syslog(3C), proc(4), attributes(5)

madv.so.1(1)

NOTES | The advice is inherited. A child process has the same advice as its parent. On `exec()` (see `exec(2)`), the advice is set back to the default system advice unless different advice has been configured via the `madv` shared object.

Advice is only applied to `mmap` regions explicitly created by the user program. Those regions established by the run-time linker or by system libraries making direct system calls (for example, `libthread` allocations for thread stacks) are not affected.

NAME	mail, Mail – interactive message processing system					
SYNOPSIS	/usr/ucb/mail ... /usr/ucb/Mail ...

mailcompat(1)

NAME mailcompat – provide SunOS compatibility for Solaris mailbox format

DESCRIPTION mailcompat is a program to provide SunOS 4.x compatibility for the Solaris mailbox format. You would typically run mailcompat to be able to read mail on a workstation running SunOS 4.x when your mail server is running Solaris.

Enabling mailcompat creates an entry in your .forward file, if it exists. If this file does not exist, mailcompat will create it. Disabling mailcompat will remove the entry from the .forward file, and if this was the only entry, will remove the entire file.

To execute mailcompat, log onto the Solaris mail server and enter mailcompat on the command line. Answer the queries provided by the program.

USAGE See largefile(5) for the description of the behavior of mailcompat when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

EXAMPLES **EXAMPLE 1** Examples of the mailcompat feature.

The following example enables the mailcompat feature for the user "john".

```
example% mailcompat
This program can be used to store your mail in a format
that you can read with SunOS 4.X based mail readers
To enable the mailcompat feature a ".forward" file is created.
Would you like to enable the mailcompat feature? Y
Mailcompat feature ENABLED.Run mailcompat with no arguments to remove it
example%
```

The following example disables the mailcompat feature for the user "john".

```
example% mailcompat
This program can be used to store your mail in a format
that you can read with SunOS 4.X based mail readers
You have a .forward file in your home directory containing:
"|usr/bin/mailcompat johns"
Would you like to remove it and disable the mailcompat feature? y
Back to normal reception of mail.
example%
```

FILES ~/.forward list of recipients for forwarding messages

NAME	mailp, digestp, filep, newsp, filofaxp, franklinp, timemanp, timesysp – frontends to the mp Text to PDL (Printer Description Language) pretty print filter																
SYNOPSIS	<pre> mailp [<i>options</i>] <i>filename</i>... newsp [<i>options</i>] <i>filename</i>... digestp [<i>options</i>] <i>filename</i>... filep [<i>options</i>] <i>filename</i>... filofaxp [<i>options</i>] <i>filename</i>... franklinp [<i>options</i>] <i>filename</i>... timemanp [<i>options</i>] <i>filename</i>... timesysp [<i>options</i>] <i>filename</i>...</pre>																
DESCRIPTION	<p>The mailp utility is a frontend to the mp(1) program. It uses different names to provide various mp options:</p> <table border="0"> <tr><td>mailp</td><td>Prints out mail messages.</td></tr> <tr><td>newsp</td><td>Prints out USENET news articles.</td></tr> <tr><td>digestp</td><td>Prints out USENET digest files.</td></tr> <tr><td>filep</td><td>Prints out ordinary ASCII files.</td></tr> <tr><td>filofaxp</td><td>Prints out in Filofax personal organiser format.</td></tr> <tr><td>franklinp</td><td>Prints out in Franklin Planner personal organiser format.</td></tr> <tr><td>timemanp</td><td>Prints out in Time Manager personal organiser format.</td></tr> <tr><td>timesysp</td><td>Prints out in Time/System International personal organiser format.</td></tr> </table> <p>mailp and the associated programs read each <i>filename</i> in sequence and generate a prettified version of the contents. If no filename arguments are provided, mailp reads the standard input.</p> <p>mailp works in two ways. With the -D option, it will work as an X print server client to produce the PDL of the target printer and spool it. With the -d or -P option, it will generate and spool PostScript™ output.</p>	mailp	Prints out mail messages.	newsp	Prints out USENET news articles.	digestp	Prints out USENET digest files.	filep	Prints out ordinary ASCII files.	filofaxp	Prints out in Filofax personal organiser format.	franklinp	Prints out in Franklin Planner personal organiser format.	timemanp	Prints out in Time Manager personal organiser format.	timesysp	Prints out in Time/System International personal organiser format.
mailp	Prints out mail messages.																
newsp	Prints out USENET news articles.																
digestp	Prints out USENET digest files.																
filep	Prints out ordinary ASCII files.																
filofaxp	Prints out in Filofax personal organiser format.																
franklinp	Prints out in Franklin Planner personal organiser format.																
timemanp	Prints out in Time Manager personal organiser format.																
timesysp	Prints out in Time/System International personal organiser format.																
OPTIONS	<p>The following options are supported:</p> <table border="0"> <tr> <td style="padding-right: 20px;">-d <i>printer</i></td> <td>Sends output to the named printer. Otherwise, sends output to the printer named in the PRINTER environment variable.</td> </tr> <tr> <td style="padding-right: 20px;">-D</td> <td>Generates the PDL for the target printer and spools it to the printer.</td> </tr> <tr> <td style="padding-right: 20px;">-F</td> <td>Instead of printing who the mail article is <i>for</i>, the top header will contain who the mail article is <i>from</i>. This is a useful option for people with their own personal printer.</td> </tr> </table>	-d <i>printer</i>	Sends output to the named printer. Otherwise, sends output to the printer named in the PRINTER environment variable.	-D	Generates the PDL for the target printer and spools it to the printer.	-F	Instead of printing who the mail article is <i>for</i> , the top header will contain who the mail article is <i>from</i> . This is a useful option for people with their own personal printer.										
-d <i>printer</i>	Sends output to the named printer. Otherwise, sends output to the printer named in the PRINTER environment variable.																
-D	Generates the PDL for the target printer and spools it to the printer.																
-F	Instead of printing who the mail article is <i>for</i> , the top header will contain who the mail article is <i>from</i> . This is a useful option for people with their own personal printer.																

mailp(1)

- h Banner printing is disabled. Most of the information that typically appears on the banner sheet is output in the mp banners.
- l Formats output in landscape mode. Two pages of text will be printed per sheet of paper.
- P *printer* Same as -d option.
- s *subject* Uses *subject* as the new subject for the printout. If you are printing ordinary ASCII files which have been specified on the command line, the subject will default to the name of each of these files.

OPERANDS The following operand is supported:

filename The name of the file to be read.

ENVIRONMENT VARIABLES If none of the -d, -D, or -P options is used, mailp uses the PRINTER environment variable to determine the printer to which the output from the mp(1) program is sent. If the PRINTER variable is not found, the default destination is the PostScript™ printer.

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmp

SEE ALSO mp(1), attributes(5)

NOTES The -P option, which spools the PDL directly to the target printer in mp(1), produces PostScript™ when used in mailp so as to be backward compatible.

NAME	mailq – print the mail queue
SYNOPSIS	<code>/usr/bin/mailq [-q <i>subarg</i>] [-v]</code>
DESCRIPTION	<p>The mailq utility displays a summary of the mail messages queued for future delivery.</p> <p>The first line displayed for each mail message shows the internal identifier used on this host for the message, the size of the message in bytes, the date and time the message was accepted into the queue, and the envelope sender of the message. The second line of the display shows the error message that caused this message to be retained in the queue. This line will not be displayed if the message is being processed for the first time.</p> <p>The mailq utility used to be identical to sendmail -bp. Now it checks for the authorization attribute, solaris.mail.mailq. If the check for the invoking user succeeds, sendmail -bp is executed with the remaining argument vector. Otherwise, an error message is printed. This authorization attribute is by default enabled for all users. It can be disabled by modifying the Basic Solaris User entry in prof_attr(4).</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -qp[<i>time</i>] Similar to -q<i>time</i>, except that instead of periodically forking a child to process the queue, sendmail forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time is given as the argument. The sleep time default is 1 second. The process will always sleep at least 5 seconds if the queue was empty in the previous queue run. -qf Processes saved messages in the queue once and does not fork(), but runs in the foreground. -qG <i>name</i> Processes jobs in the queue group called <i>name</i> only. -q[!]I <i>substr</i> Limits processed jobs to those containing <i>substr</i> as a substring of the queue id, or not when ! is specified. -q[!]R <i>substr</i> Limits processed jobs to those containing <i>substr</i> as a substring of one of the recipients, or not when ! is specified. -q[!]S <i>substr</i> Limits processed jobs to those containing <i>substr</i> as a substring of the sender, or not when ! is specified. -v Prints verbose information. This adds the priority of the message and a single character indicator (+ or blank) indicating whether a warning message has been sent on the first line of the message. Additionally, extra lines may be intermixed with the recipients that indicate the "controlling user" information. This shows who will own any programs that are executed on behalf of this message and the name of the alias this command is expanded from, if any.
EXIT STATUS	0 Successful completion.

mailq(1)

>0 An error occurred.

NAME	mailstats – print statistics collected by sendmail																
SYNOPSIS	mailstats [-o] [-c] [-C <i>configfile</i>] [-f <i>statisticsfile</i>] [-p] [-P]																
DESCRIPTION	<p>The mailstats utility prints out the statistics collected by the sendmail(1M) program on mailer usage. These statistics are collected if the file indicated by the StatusFile configuration option of sendmail (defined in /etc/mail/sendmail.cf) exists. The default statistics file is /etc/mail/statistics.</p> <p>To enable mailstats, you must, as root, touch /etc/mail/statistics. See the StatusFile processing option in sendmail(1M).</p> <p>mailstats first prints the time that the statistics file was created and the last time it was modified. Then, the statistics for each mailer are displayed on a single line, each with the following whitespace-separated fields:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">M</td> <td>The mailer number.</td> </tr> <tr> <td>msgsf</td> <td>Number of messages from the mailer.</td> </tr> <tr> <td>bytes_from</td> <td>Kbytes from the mailer.</td> </tr> <tr> <td>msgsto</td> <td>Number of messages to the mailer.</td> </tr> <tr> <td>bytes_to</td> <td>Kbytes to the mailer.</td> </tr> <tr> <td>msgsj</td> <td>Number of messages rejected by the mailer.</td> </tr> <tr> <td>msgsd</td> <td>Number of messages discarded by the mailer.</td> </tr> <tr> <td>Mailer</td> <td>The name of the mailer.</td> </tr> </table> <p>After this display, a line totaling the values for all of the mailers is displayed, separated from the previous information by a line containing only equal sign (=) characters.</p> <p>To reinitialize the statistics file once a night, add an entry to root's crontab(1):</p> <pre>mailstats -p > /dev/null</pre>	M	The mailer number.	msgsf	Number of messages from the mailer.	bytes_from	Kbytes from the mailer.	msgsto	Number of messages to the mailer.	bytes_to	Kbytes to the mailer.	msgsj	Number of messages rejected by the mailer.	msgsd	Number of messages discarded by the mailer.	Mailer	The name of the mailer.
M	The mailer number.																
msgsf	Number of messages from the mailer.																
bytes_from	Kbytes from the mailer.																
msgsto	Number of messages to the mailer.																
bytes_to	Kbytes to the mailer.																
msgsj	Number of messages rejected by the mailer.																
msgsd	Number of messages discarded by the mailer.																
Mailer	The name of the mailer.																
OPTIONS	<p>The following options are supported:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">-c</td> <td>Tries to use submit.cf instead of the default sendmail configuration file.</td> </tr> <tr> <td>-C <i>configfile</i></td> <td>Specifies a sendmail configuration file.</td> </tr> <tr> <td>-f <i>statisticsfile</i></td> <td>Specifies a sendmail statistics file.</td> </tr> <tr> <td>-o</td> <td>Does not display the name of the mailer in the output.</td> </tr> <tr> <td>-p</td> <td>Outputs information in program-readable mode and clear statistics.</td> </tr> </table>	-c	Tries to use submit.cf instead of the default sendmail configuration file.	-C <i>configfile</i>	Specifies a sendmail configuration file.	-f <i>statisticsfile</i>	Specifies a sendmail statistics file.	-o	Does not display the name of the mailer in the output.	-p	Outputs information in program-readable mode and clear statistics.						
-c	Tries to use submit.cf instead of the default sendmail configuration file.																
-C <i>configfile</i>	Specifies a sendmail configuration file.																
-f <i>statisticsfile</i>	Specifies a sendmail statistics file.																
-o	Does not display the name of the mailer in the output.																
-p	Outputs information in program-readable mode and clear statistics.																

mailstats(1)

-P Outputs information in program-readable mode without clearing statistics.

USAGE See `largefile(5)` for the description of the behavior of `mailstats` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES `/dev/null` zero-lined file
`/etc/mail/statistics` default `sendmail` statistics file
`/etc/mail/sendmail.cf` default `sendmail` configuration file

NAME	mailx, mail – interactive message processing system
SYNOPSIS	<pre>mailx [-BdeHiInNURvV~] [-f [file +folder]] [-T file] [-u user] mailx [-BdFintUv~] [-b bcc] [-c cc] [-h number] [-r address] [-s subject] recipient... /usr/ucb/mail ... /usr/ucb/Mail ...</pre>
DESCRIPTION	<p>The mail utilities listed above provide a comfortable, flexible environment for sending and receiving mail messages electronically.</p> <p>When reading mail, the mail utilities provide commands to facilitate saving, deleting, and responding to messages. When sending mail, the mail utilities allow editing, reviewing and other modification of the message as it is entered.</p> <p>Incoming mail is stored in a standard file for each user, called the <code>mailbox</code> for that user. When the mail utilities are called to read messages, the <code>mailbox</code> is the default place to find them. As messages are read, they are marked to be moved to a secondary file for storage, unless specific action is taken, so that the messages need not be seen again. This secondary file is called the <code>mbox</code> and is normally located in the user's <code>HOME</code> directory (see <code>MBOX</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file). Messages can be saved in other secondary files named by the user. Messages remain in a secondary file until forcibly removed.</p> <p>The user can access a secondary file by using the <code>-f</code> option. Messages in the secondary file can then be read or otherwise processed using the same Commands as in the primary <code>mailbox</code>. This gives rise within these pages to the notion of a current <code>mailbox</code>.</p>
OPTIONS	<p>On the command line options start with a dash (-). Any other arguments are taken to be destinations (recipients). If no recipients are specified, <code>mailx</code> attempts to read messages from the <code>mailbox</code>.</p> <ul style="list-style-type: none"> -B Do not buffer standard input or standard output. -b <i>bcc</i> Set the blind carbon copy list to <i>bcc</i>. <i>bcc</i> should be enclosed in quotes if it contains more than one name. -c <i>cc</i> Set the carbon copy list to <i>cc</i>. <i>cc</i> should be enclosed in quotes if it contains more than one name. -d Turn on debugging output. (Neither particularly interesting nor recommended.) -e Test for the presence of mail. <code>mailx</code> prints nothing and exits with a successful return code if there is mail to read. -F Record the message in a file named after the first recipient. Overrides the <code>record</code> variable, if set (see <code>Internal Variables</code>).

mailx(1)

-f <i>[file]</i>	Read messages from <i>file</i> instead of mailbox. If no <i>file</i> is specified, the mbox is used.
-f [+ <i>folder</i>]	Use the file <i>folder</i> in the folder directory (same as the <i>folder</i> command). The name of this directory is listed in the <i>folder</i> variable.
-H	Print header summary only.
-h <i>number</i>	The number of network “hops” made so far. This is provided for network software to avoid infinite delivery loops. This option and its argument are passed to the delivery program.
-I	Include the newsgroup and article-id header lines when printing mail messages. This option requires the -f option to be specified.
-i	Ignore interrupts. See also <i>ignore</i> in Internal Variables.
-N	Do not print initial header summary.
-n	Do not initialize from the system default <i>mailx.rc</i> or <i>Mail.rc</i> file. See USAGE.
-r <i>address</i>	Use <i>address</i> as the return address when invoking the delivery program. All tilde commands are disabled. This option and its argument is passed to the delivery program.
-s <i>subject</i>	Set the Subject header field to <i>subject</i> . <i>subject</i> should be enclosed in quotes if it contains embedded white space.
-T <i>file</i>	Message-id and article-id header lines are recorded in <i>file</i> after the message is read. This option also sets the -I option.
-t	Scan the input for To:, Cc:, and Bcc: fields. Any recipients on the command line will be ignored.
-U	Convert UUCP-style addresses to internet standards. Overrides the <i>conv</i> environment variable.
-u <i>user</i>	Read <i>user</i> 's mailbox. This is only effective if <i>user</i> 's mailbox is not read protected.
-V	Print the mailx version number and exit.
-v	Pass the -v flag to <i>sendmail(1M)</i> .
--	Interpret tilde escapes in the input even if not reading from a tty.

OPERANDS The following operands are supported:

recipient Addressee of message.

Starting Mail At startup time, mailx executes the system startup file */etc/mail/mailx.rc*. If invoked as *mail* or *Mail*, the system startup file */etc/mail/Mail.rc* is used instead.

The system startup file sets up initial display options and alias lists and assigns values to some internal variables. These variables are flags and valued parameters which are set and cleared using the `set` and `unset` commands. See *Internal Variables*.

With the following exceptions, regular commands are legal inside startup files: `!`, `Copy`, `edit`, `followup`, `Followup`, `hold`, `mail`, `preserve`, `reply`, `Reply`, `shell`, and `visual`. An error in the startup file causes the remaining lines in the file to be ignored.

After executing the system startup file, the mail utilities execute the optional personal startup file `$HOME/.mailrc`, wherein the user can override the values of the internal variables as set by the system startup file.

If the `-n` option is specified, however, the mail utilities do not execute the system startup file.

Many system administrators include the commands

```
set appenddeadletter
unset replyall
unset pipeignore
```

in the system startup files (to be compatible with past Solaris behavior), but this does not meet standards requirements for `mailx`. To get standard behavior for `mailx`, users should use the `-n` option or include the following commands in a personal startup file:

```
unset appenddeadletter
set replyall
set pipeignore
```

When reading mail, the mail utilities are in *command mode*. A header summary of the first several messages is displayed, followed by a prompt indicating the mail utilities can accept regular commands (see *Commands* below). When sending mail, the mail utilities are in *input mode*. If no subject is specified on the command line, and the `asksub` variable is set, a prompt for the subject is printed.

As the message is typed, the mail utilities read the message and store it in a temporary file. Commands may be entered by beginning a line with the tilde (`~`) escape character followed by a single command letter and optional arguments. See *Tilde Escapes* for a summary of these commands.

Reading Mail

Each message is assigned a sequential number, and there is at any time the notion of a current message, marked by a right angle bracket (`>`) in the header summary. Many commands take an optional list of messages (*message-list*) to operate on. In most cases, the current message is set to the highest-numbered message in the list after the command is finished executing.

The default for *message-list* is the current message. A *message-list* is a list of message identifiers separated by spaces, which may include:

n Message number *n*.

mailx(1)

.	The current message.
^	The first undeleted message.
\$	The last message.
*	All messages.
+	The next undeleted message.
-	The previous undeleted message.
<i>n-m</i>	An inclusive range of message numbers.
<i>user</i>	All messages from <i>user</i> .
<i>/string</i>	All messages with <i>string</i> in the Subject line (case ignored).
<i>:c</i>	All messages of type <i>c</i> , where <i>c</i> is one of: d deleted messages n new messages o old messages r read messages u unread messages

Notice that the context of the command determines whether this type of message specification makes sense.

Other arguments are usually arbitrary strings whose usage depends on the command involved. Filenames, where expected, are expanded using the normal shell conventions (see `sh(1)`). Special characters are recognized by certain commands and are documented with the commands below.

Sending Mail

Recipients listed on the command line may be of three types: login names, shell commands, or alias groups. Login names may be any network address, including mixed network addressing. If mail is found to be undeliverable, an attempt is made to return it to the sender's mailbox. If the recipient name begins with a pipe symbol (`|`), the rest of the name is taken to be a shell command to pipe the message through. This provides an automatic interface with any program that reads the standard input, such as `lp(1)` for recording outgoing mail on paper. Alias groups are set by the `alias` command (see `Commands` below) or in a system startup file (for example, `$HOME/.mailrc`). Aliases are lists of recipients of any type.

Forwarding Mail

To forward a specific message, include it in a message to the desired recipients with the `~f` or `~m` tilde escapes. See `Tilde Escapes` below. To forward mail automatically, add a comma-separated list of addresses for additional recipients to the `.forward` file in your home directory. This is different from the format of the `alias` command,

which takes a space-separated list instead. *Note:* Forwarding addresses must be valid, or the messages will “bounce.” You cannot, for instance, reroute your mail to a new host by forwarding it to your new address if it is not yet listed in the NIS aliases domain.

Commands Regular commands are of the form

[*command*] [*message-list*] [*arguments*]

In *input mode*, commands are recognized by the escape character, tilde (~), and lines not treated as commands are taken as input for the message. If no command is specified in *command mode*, next is assumed. The following is a complete list of mailx commands:

!*shell-command*

Escape to the shell. See SHELL in ENVIRONMENT VARIABLES.

comment

NULL command (comment). Useful in mailrc files.

=

Print the current message number.

?

Prints a summary of commands.

alias *alias name* . . .

group *alias name* . . .

Declare an alias for the given names. The names are substituted when alias is used as a recipient. Useful in the mailrc file. With no arguments, the command displays the list of defined aliases.

alternates *name* . . .

Declare a list of alternate names for your login. When responding to a message, these names are removed from the list of recipients for the response. With no arguments, print the current list of alternate names. See also allnet in Internal Variables.

cd [*directory*]

chdir [*directory*]

Change directory. If *directory* is not specified, \$HOME is used.

copy [*file*]

copy [*message-list*] *file*

Copy messages to the file without marking the messages as saved. Otherwise equivalent to the save command.

Copy [*message-list*]

Save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise equivalent to the Save command.

mailx(1)

`delete` [*message-list*]

Delete messages from the mailbox. If `autoprint` is set, the next message after the last one deleted is printed (see `Internal Variables`).

`discard` [*header-field*. . .]

`ignore` [*header-field*. . .]

Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are `Status` and `Received`. The fields are included when the message is saved, unless the `alwaysignore` variable is set. The `More`, `Page`, `Print`, and `Type` commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the `undiscard` and `unignore` commands.

`dp` [*message-list*]

`dt` [*message-list*]

Delete the specified messages from the mailbox and print the next message after the last one deleted. Roughly equivalent to a `delete` command followed by a `print` command.

`echo` *string* . . .

Echo the given strings (like `echo(1)`).

`edit` [*message-list*]

Edit the given messages. Each message is placed in a temporary file and the program named by the `EDITOR` variable is invoked to edit it (see `ENVIRONMENT VARIABLES`). Default editor is `ed(1)`.

`exit`

`xit`

Exit from `mailx`, without changing the mailbox. No messages are saved in the `mbox` (see also `quit`).

`field` [*message-list*] *header-file*

Display the value of the header field in the specified message.

`file` [*file*]

`folder` [*file*]

Quit from the current file of messages and read in the specified file. Several special characters are recognized when used as file names:

`%` the current mailbox.

`%user` the mailbox for *user*.

`#` the previous mail file.

`&` the current `mbox`.

`+file` The named file in the *folder* directory (listed in the `folder` variable).

With no arguments, print the name of the current mail file, and the number of messages and characters it contains.

folders

Print the names of the files in the directory set by the `folder` variable (see `Internal Variables`).

Followup [*message*]

Respond to a message, recording the response in a file whose name is derived from the author of the message. Overrides the `record` variable, if set. If the `replyall` variable is set, the actions of `Followup` and `followup` are reversed. See also the `followup`, `Save`, and `Copy` commands and `outfolder` in `Internal Variables`, and the `Starting Mail` section in `USAGE` above.

followup [*message-list*]

Respond to the first message in the *message-list*, sending the message to the author of each message in the *message-list*. The subject line is taken from the first message and the response is recorded in a file whose name is derived from the author of the first message. If the `replyall` variable is set, the actions of `followup` and `Followup` are reversed. See also the `Followup`, `Save`, and `Copy` commands and `outfolder` in `Internal Variables`, and the `Starting Mail` section in `USAGE` above.

from [*message-list*]

Print the header summary for the specified messages. If no messages are specified, print the header summary for the current message.

group *alias name* . . .**alias** *alias name* . . .

Declare an alias for the given names. The names are substituted when `alias` is used as a recipient. Useful in the `mailrc` file.

headers [*message*]

Print the page of headers which includes the message specified. The `screen` variable sets the number of headers per page (see `Internal Variables`). See also the `z` command.

help

Print a summary of commands.

hold [*message-list*]**preserve** [*message-list*]

Hold the specified messages in the mailbox.

if *s* | *r* | *t**mail-commands***else***mail-commands***endif**

Conditional execution, where *s* executes following *mail-commands*, up to an `else` or `endif`, if the program is in *send* mode, *r* causes the *mail-commands* to be executed only in *receive* mode, and *t* causes the *mail-commands* to be executed only if `mailx` is being run from a terminal. Useful in the `mailrc` file.

mailx(1)

inc

Incorporate messages that arrive while you are reading the system mailbox. The new messages are added to the message list in the current mail session. This command does not commit changes made during the session, and prior messages are not renumbered.

ignore [*header-field* ...]

discard [*header-field* ...]

Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are `Status` and `Cc`. All fields are included when the message is saved. The `More`, `Page`, `Print` and `Type` commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the `undiscard` and `unignore` commands.

list

Print all commands available. No explanation is given.

load

[message] *file* The specified message is replaced by the message in the named file. *file* should contain a single mail message including mail headers (as saved by the `save` command).

mail *recipient* ...

Mail a message to the specified recipients.

Mail *recipient*

Mail a message to the specified recipients, and record it in a file whose name is derived from the author of the message. Overrides the `record` variable, if set. See also the `Save` and `Copy` commands and `outfolder` in `Internal Variables`.

mbox [*message-list*]

Arrange for the given messages to end up in the standard mbox save file when `mailx` terminates normally. See `MBOX` in `ENVIRONMENT VARIABLES` for a description of this file. See also the `exit` and `quit` commands.

more [*message-list*]

page [*message-list*]

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)` or if the `bsdcompat` variable is set, the default is `more(1)`. See `ENVIRONMENT VARIABLES`. Same as the `print` and `type` commands.

More [*message-list*]

Page [*message-list*]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command. Same as the `Print` and `Type` commands.

new [*message-list*]

New [*message-list*]

unread [*message-list*]

Unread

[*message-list*] Take a message list and mark each message as *not* having been read.

next [*message*]

Go to the next message matching *message*. If *message* is not supplied, this command finds the next message that was not deleted or saved. A *message-list* may be specified, but in this case the first valid message in the list is the only one used. This is useful for jumping to the next message from a specific user, since the name would be taken as a command in the absence of a real command. See the discussion of *message-list* above for a description of possible message specifications.

pipe [*message-list*] [*shell-command*]

| [*message-list*] [*shell-command*]

Pipe the message through the given *shell-command*. The message is treated as if it were read. If no arguments are given, the current message is piped through the command specified by the value of the `cmd` variable. If the `page` variable is set, a form feed character is inserted after each message (see Internal Variables).

preserve [*message-list*]hold [*message-list*]

Preserve the specified messages in the mailbox.

print [*message-list*]type [*message-list*]

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)` or if the `bsdcompat` variable is set, the default is `more(1)`. See ENVIRONMENT VARIABLES. Same as the `more` and `page` commands.

Print [*message-list*]Type [*message-list*]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command. Same as the `More` and `Page` commands.

put [*file*]put [*message-list*] *file*

Save the specified message in the given file. Use the same conventions as the `print` command for which header fields are ignored.

Put [*file*]Put [*message-list*] *file*

Save the specified message in the given file. Overrides suppression of fields by the `ignore` command.

quit

Exit from `mailx`, storing messages that were read in `mbox` and unread messages in the mailbox. Messages that have been explicitly saved in a file are deleted unless the `keepsave` variable is set.

mailx(1)

reply [*message-list*]

respond [*message-list*]

replysender [*message-list*]

Send a response to the author of each message in the *message-list*. The subject line is taken from the first message. If *record* is set to a file, a copy of the reply is added to that file. If the *replyall* variable is set, the actions of Reply/Respond and reply/respond are reversed. The *replysender* command is not affected by the *replyall* variable, but sends each reply only to the sender of each message. See the Starting Mail section in USAGE above.

Reply [*message*]

Respond [*message*]

replyall [*message*]

Reply to the specified message, including all other recipients of that message. If the variable *record* is set to a file, a copy of the reply added to that file. If the *replyall* variable is set, the actions of Reply/Respond and reply/respond are reversed. The *replyall* command is not affected by the *replyall* variable, but always sends the reply to all recipients of the message. See the Starting Mail section in USAGE above.

retain

Add the list of header fields named to the *retained list*. Only the header fields in the retain list are shown on your terminal when you print a message. All other header fields are suppressed. The set of retained fields specified by the *retain* command overrides any list of ignored fields specified by the *ignore* command. The *Type* and *Print* commands can be used to print a message in its entirety. If *retain* is executed with no arguments, it lists the current set of retained fields.

Save [*message-list*]

Save the specified messages in a file whose name is derived from the author of the first message. The name of the file is taken to be the author's name with all network addressing stripped off. See also the *Copy*, *followup*, and *Followup* commands and *outfolder* in Internal Variables.

save [*file*]

save [*message-list*] *file*

Save the specified messages in the given file. The file is created if it does not exist. The file defaults to *mbox*. The message is deleted from the mailbox when *mailx* terminates unless *keepsave* is set (see also Internal Variables and the *exit* and *quit* commands).

set

set *variable*

set *variable=string*

set *variable=number*

Define a *variable*. To assign a *value* to *variable*, separate the variable name from the value by an '=' (there must be no space before or after the '='). A variable may be given a null, string, or numeric *value*. To embed SPACE characters within a *value*, enclose it in quotes.

With no arguments, set displays all defined variables and any values they might have. See *Internal Variables* for a description of all predefined mail variables.

shell

Invoke an interactive shell. See also SHELL in ENVIRONMENT VARIABLES.

size [*message-list*]

Print the size in characters of the specified messages.

source *file*

Read commands from the given file and return to command mode.

top [*message-list*]

Print the top few lines of the specified messages. If the *toplines* variable is set, it is taken as the number of lines to print (see *Internal Variables*). The default is 5.

touch [*message-list*]

Touch the specified messages. If any message in *message-list* is not specifically saved in a file, it is placed in the *mbox*, or the file specified in the MBOX environment variable, upon normal termination. See *exit* and *quit*.

Type [*message-list*]**Print** [*message-list*]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the *ignore* command.

type [*message-list*]**print** [*message-list*]

Print the specified messages. If *crt* is set, the messages longer than the number of lines specified by the *crt* variable are paged through the command specified by the *PAGER* variable. The default command is *pg(1)*. See ENVIRONMENT VARIABLES.

unalias [*alias*] ...**ungroup** [*alias*] ...

Remove the definitions of the specified aliases.

undelete [*message-list*]

Restore the specified deleted messages. Will only restore messages deleted in the current mail session. If *autoprint* is set, the last message of those restored is printed (see *Internal Variables*).

undiscard [*header-field* ...]**unignore** [*header-field* ...]

Remove the specified header fields from the list being ignored. If no header fields are specified, all header fields are removed from the list being ignored.

unretain [*header-field* ...]

Remove the specified header fields from the list being retained. If no header fields are specified, all header fields are removed from the list being retained.

unread [*message-list*]

Unread [*message-list*] Same as the *new* command.

mailx(1)

`unset variable . . .`
Erase the specified variables. If the variable was imported from the environment (that is, an environment variable or exported shell variable), it cannot be unset from within mailx.

`version`
Print the current version and release date of the mailx utility.

`visual [message-list]`
Edit the given messages with a screen editor. Each messages is placed in a temporary file and the program named by the VISUAL variable is invoked to edit it (see ENVIRONMENT VARIABLES). Notice that the default visual editor is vi.

`write [message-list] file`
Write the given messages on the specified file, minus the header and trailing blank line. Otherwise equivalent to the save command.

`xit`
`exit`
Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

`z[+ | -]`
Scroll the header display forward or backward one screen-full. The number of headers displayed is set by the screen variable (see Internal Variables).

Tilde Escapes

The following tilde escape commands can be used when composing mail to send. These may be entered only from *input mode*, by beginning a line with the tilde escape character (~). See `escape` in Internal Variables for changing this special character. The escape character can be entered as text by typing it twice.

<code>~ !<i>shell-command</i></code>	Escape to the shell. If present, run <i>shell-command</i> .
<code>~.</code>	Simulate end of file (terminate message input).
<code>~ :<i>mail-command</i></code>	
<code>~_ <i>mail-command</i></code>	Perform the command-level request. Valid only when sending a message while reading mail.
<code>~?</code>	Print a summary of tilde escapes.
<code>~A</code>	Insert the autograph string <code>Sign</code> into the message (see Internal Variables).
<code>~a</code>	Insert the autograph string <code>sign</code> into the message (see Internal Variables).
<code>~b <i>name</i> . . .</code>	Add the <i>names</i> to the blind carbon copy (Bcc) list. This is like the carbon copy (Cc) list, except that the names in the Bcc list are not shown in the header of the mail message.
<code>~c <i>name</i> . . .</code>	Add the <i>names</i> to the carbon copy (Cc) list.

~d	Read in the <code>dead-letter</code> file. See <code>DEAD</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file.
~e	Invoke the editor on the partial message. See also <code>EDITOR</code> in <code>ENVIRONMENT VARIABLES</code> .
~f [<i>message-list</i>]	Forward the specified message, or the current message being read. Valid only when sending a message while reading mail. The messages are inserted into the message without alteration (as opposed to the ~m escape).
~F [<i>message-list</i>]	Forward the specified message, or the current message being read, including all header fields. Overrides the suppression of fields by the <code>ignore</code> command.
~h	Prompt for Subject line and To, Cc, and Bcc lists. If the field is displayed with an initial value, it may be edited as if you had just typed it.
~i <i>variable</i>	Insert the value of the named variable into the text of the message. For example, ~A is equivalent to '~i Sign.' Environment variables set and exported in the shell are also accessible by ~i.
~m [<i>message-list</i>]	Insert the listed messages, or the current message being read into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line.
~M [<i>message-list</i>]	Insert the listed messages, or the current message being read, including the header fields, into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line. Overrides the suppression of fields by the <code>ignore</code> command.
~p	Print the message being entered.
~q	Quit from input mode by simulating an interrupt. If the body of the message is not null, the partial message is saved in <code>dead-letter</code> . See <code>DEAD</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file.
~R	Mark message for return receipt.

mailx(1)

<code>~r file</code>	
<code>~< file</code>	
<code>~< ! shell-command</code>	Read in the specified file. If the argument begins with an exclamation point (!), the rest of the string is taken as an arbitrary shell command and is executed, with the standard output inserted into the message.
<code>~s string ...</code>	Set the subject line to <i>string</i> .
<code>~t name ...</code>	Add the given <i>names</i> to the To list.
<code>~v</code>	Invoke a preferred screen editor on the partial message. The default visual editor is <code>vi(1)</code> . See also <code>VISUAL</code> in ENVIRONMENT VARIABLES.
<code>~w file</code>	Write the message into the given file, without the header.
<code>~x</code>	Exit as with <code>~q</code> except the message is not saved in <code>dead-letter</code> .
<code>~ shell-command</code>	Pipe the body of the message through the given <i>shell-command</i> . If the <i>shell-command</i> returns a successful exit status, the output of the command replaces the message.

Internal Variables

The following variables are internal variables. They may be imported from the execution environment or set using the `set` command at any time. The `unset` command may be used to erase variables.

<code>allnet</code>	All network names whose last component (login name) match are treated as identical. This causes the <i>message-list</i> message specifications to behave similarly. Disabled by default. See also the <code>alternates</code> command and the <code>metoo</code> and <code>fuzzymatch</code> variables.
<code>alwaysignore</code>	Ignore header fields with <code>ignore</code> everywhere, not just during <code>print</code> or <code>type</code> . Affects the <code>save</code> , <code>Save</code> , <code>copy</code> , <code>Copy</code> , <code>top</code> , <code>pipe</code> , and <code>write</code> commands, and the <code>~m</code> and <code>~f</code> tilde escapes. Enabled by default.
<code>append</code>	Upon termination, append messages to the end of the <code>mbox</code> file instead of prepending them. Although disabled by default, <code>append</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).
<code>appenddeadletter</code>	Append to the <code>deadletter</code> file rather than overwrite it. Although disabled by default, <code>appenddeadletter</code> is frequently set in the system startup file. See <i>Starting Mail</i> in <code>USAGE</code> above.

askbcc	Prompt for the Bcc list after the Subject is entered if it is not specified on the command line with the -b option. Disabled by default.				
askcc	Prompt for the Cc list after the Subject is entered if it is not specified on the command line with the -c option. Disabled by default.				
asksub	Prompt for subject if it is not specified on the command line with the -s option. Enabled by default.				
autoinc	Automatically incorporate new messages into the current session as they arrive. This has an affect similar to issuing the inc command every time the command prompt is displayed. Disabled by default, but autoinc is set in the default system startup file for mailx; it is not set for /usr/ucb/mail or /usr/ucb/Mail.				
autoprint	Enable automatic printing of messages after delete and undelete commands. Disabled by default.				
bang	Enable the special-casing of exclamation points (!) in shell escape command lines as in vi(1). Disabled by default.				
bsdcompat	Set automatically if mailx is invoked as mail or Mail. Causes mailx to use /etc/mail/Mail.rc as the system startup file. Changes the default pager to more(1).				
cmd= <i>shell-command</i>	Set the default command for the pipe command. No default value.				
conv= <i>conversion</i>	Convert uucp addresses to the specified address style, which can be either: <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;">internet</td> <td>This requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing.</td> </tr> <tr> <td style="padding-right: 10px;">optimize</td> <td>Remove loops in uucp(1C) address paths (typically generated by the reply command). No rerouting is performed; mail has no knowledge of UUCP routes or connections.</td> </tr> </table> <p>Conversion is disabled by default. See also sendmail(1M) and the -U command-line option.</p>	internet	This requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing.	optimize	Remove loops in uucp(1C) address paths (typically generated by the reply command). No rerouting is performed; mail has no knowledge of UUCP routes or connections.
internet	This requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing.				
optimize	Remove loops in uucp(1C) address paths (typically generated by the reply command). No rerouting is performed; mail has no knowledge of UUCP routes or connections.				
crt[= <i>number</i>]	Pipe messages having more than <i>number</i> lines through the command specified by the value of the PAGER				

mailx(1)

	variable (<code>pg(1)</code> or <code>more(1)</code> by default). If <i>number</i> is not specified, the current window size is used. Disabled by default.
<code>debug</code>	Enable verbose diagnostics for debugging. Messages are not delivered. Disabled by default.
<code>dot</code>	Take a period on a line by itself, or EOF during input from a terminal as end-of-file. Disabled by default, but <code>dot</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).
<code>fcc</code>	By default, <code>mailx</code> will treat any address containing a slash ("/") character as a local "send to file" address. By unsetting this option, this behavior is disabled. Enabled by default.
<code>flipr</code>	Reverse the effect of the <code>followup/Followup</code> and <code>reply/Reply</code> command pairs. If both <code>flipr</code> and <code>replyall</code> are set, the effect is as if neither was set.
<code>from</code>	Extract the author listed in the header summary from the <code>From:</code> header instead of the UNIX <code>From</code> line. Enabled by default.
<code>fuzzymatch</code>	The <code>from</code> command searches for messages from the indicated sender. By default, the full sender address must be specified. By setting this option, only a sub-string of the sender address need be specified. Disabled by default.
<code>escape=c</code>	Substitute <i>c</i> for the <code>~</code> escape character. Takes effect with next message sent.
<code>folder=directory</code>	The directory for saving standard mail files. User-specified file names beginning with a plus (+) are expanded by preceding the file name with this directory name to obtain the real file name. If <i>directory</i> does not start with a slash (/), <code>\$HOME</code> is prepended to it. There is no default for the <code>folder</code> variable. See also <code>outfolder</code> below.
<code>header</code>	Enable printing of the header summary when entering <code>mailx</code> . Enabled by default.
<code>hold</code>	Preserve all messages that are read in the mailbox instead of putting them in the standard <code>mbox</code> save file. Disabled by default.
<code>ignore</code>	Ignore interrupts while entering messages. Handy for noisy dial-up lines. Disabled by default.

<code>ignoreeof</code>	Ignore end-of-file during message input. Input must be terminated by a period (.) on a line by itself or by the <code>~.</code> command. See also <code>dot</code> above. Disabled by default.
<code>indentprefix=string</code>	When <code>indentprefix</code> is set, <i>string</i> is used to mark indented lines from messages included with <code>~m</code> . The default is a TAB character.
<code>keep</code>	When the mailbox is empty, truncate it to zero length instead of removing it. Disabled by default.
<code>iprompt=string</code>	The specified prompt string is displayed before each line on input is requested when sending a message.
<code>keepsave</code>	Keep messages that have been saved in other files in the mailbox instead of deleting them. Disabled by default.
<code>makeremote</code>	When replying to all recipients of a message, if an address does not include a machine name, it is assumed to be relative to the sender of the message. Normally not needed when dealing with hosts that support RFC822.
<code>metoo</code>	If your login appears as a recipient, do not delete it from the list. Disabled by default.
<code>mustbang</code>	Force all mail addresses to be in bang format.
<code>onehop</code>	When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag disables alteration of the recipients' addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). Disabled by default.
<code>outfolder</code>	Locate the files used to record outgoing messages in the directory specified by the <code>folder</code> variable unless the path name is absolute. Disabled by default. See <code>folder</code> above and the <code>Save</code> , <code>Copy</code> , <code>followup</code> , and <code>Followup</code> commands.
<code>page</code>	Used with the <code>pipe</code> command to insert a form feed after each message sent through the pipe. Disabled by default.
<code>pipeignore</code>	Omit ignored header when outputting to the <code>pipe</code> command. Although disabled by default, <code>pipeignore</code> is frequently set in the system startup file. See <code>Starting Mail in USAGE</code> above.

mailx(1)

postmark	Your "real name" to be included in the From line of messages you send. By default this is derived from the comment field in your passwd(4) file entry.
prompt= <i>string</i>	Set the <i>command mode</i> prompt to <i>string</i> . Default is "? ", unless the bsdcompat variable is set, then the default is "&".
quiet	Refrain from printing the opening message and version when entering mailx. Disabled by default.
record= <i>file</i>	Record all outgoing mail in <i>file</i> . Disabled by default. See also outfolder above.
replyall	Reverse the effect of the reply and Reply and followup and Followup commands. Although set by default, replayall is frequently unset in the system startup file. See flipr and Starting Mail in USAGE above.
returnaddr= <i>string</i>	The default sender address is that of the current user. This variable can be used to set the sender address to any arbitrary value. Set with caution.
save	Enable saving of messages in dead-letter on interrupt or delivery error. See DEAD for a description of this file. Enabled by default.
screen= <i>number</i>	Sets the number of lines in a screen-full of headers for the headers command. <i>number</i> must be a positive number. The default is set according to baud rate or window size. With a baud rate less than 1200, <i>number</i> defaults to 5, if baud rate is exactly 1200, it defaults to 10. If you are in a window, <i>number</i> defaults to the default window size minus 4. Otherwise, the default is 20.
sendmail= <i>shell-command</i>	Alternate command for delivering messages. <i>Note:</i> In addition to the expected list of recipients, mail also passes the -i and -m, flags to the command. Since these flags are not appropriate to other commands, you may have to use a shell script that strips them from the arguments list before invoking the desired command. Default is /usr/bin/rmail.
sendwait	Wait for background mailer to finish before returning. Disabled by default.
showname	Causes the message header display to show the sender's real name (if known) rather than their mail

	address. Disabled by default, but <code>showname</code> is set in the <code>/etc/mail/mailx.rc</code> system startup file for <code>mailx</code> .
<code>showto</code>	When displaying the header summary and the message is from you, print the recipient's name instead of the author's name.
<code>sign=string</code>	The variable inserted into the text of a message when the <code>~a</code> (autograph) command is given. No default (see also <code>~i</code> in <i>Tilde Escapes</i>).
<code>Sign=string</code>	The variable inserted into the text of a message when the <code>~A</code> command is given. No default (see also <code>~i</code> in <i>Tilde Escapes</i>).
<code>toplines=number</code>	The number of lines of header to print with the <code>top</code> command. Default is 5.
<code>verbose</code>	Invoke <code>sendmail(1M)</code> with the <code>-v</code> flag.
<code>translate</code>	<p>The name of a program to translate mail addresses. The program receives mail addresses as arguments. The program produces, on the standard output, lines containing the following data, in this order:</p> <ul style="list-style-type: none"> ■ the postmark for the sender (see the <code>postmark</code> variable) ■ translated mail addresses, one per line, corresponding to the program's arguments. Each translated address will replace the corresponding address in the mail message being sent. ■ a line containing only "y" or "n". if the line contains "y" the user will be asked to confirm that the message should be sent. <p>The <code>translate</code> program will be invoked for each mail message to be sent. If the program exits with a non-zero exit status, or fails to produce enough output, the message is not sent.</p>
Large File Behavior	See <code>largefile(5)</code> for the description of the behavior of <code>mailx</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>mailx</code> : <code>HOME</code> , <code>LANG</code> , <code>LC_CTYPE</code> , <code>LC_TIME</code> , <code>LC_MESSAGES</code> , <code>NLSPATH</code> , and <code>TERM</code> .
<code>DEAD</code>	The name of the file in which to save partial letters in case of untimely interrupt. Default is <code>\$HOME/dead.letter</code> .

mailx(1)

EDITOR	The command to run when the edit or ~e command is used. Default is ed(1).
LISTER	The command (and options) to use when listing the contents of the folder directory. The default is ls(1).
MAIL	The name of the initial mailbox file to read (in lieu of the standard system mailbox). The default is /var/mail/username .
MAILRC	The name of the startup file. Default is \$HOME/.mailrc.
MAILX_HEAD	The specified string is included at the beginning of the body of each message that is sent.
MAILX_TAIL	The specified string is included at the end of the body of each message that is sent.
MBOX	The name of the file to save messages which have been read. The exit command overrides this function, as does saving the message explicitly in another file. Default is \$HOME/mbox.
PAGER	The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is pg(1), or if the bsdcompat variable is set, the default is more(1). See Internal Variables.
SHELL	The name of a preferred command interpreter. Default is sh(1).
VISUAL	The name of a preferred screen editor. Default is vi(1).

EXIT STATUS When the -e option is specified, the following exit values are returned:

0	Mail was found.
>0	Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

0	Successful completion. Notice that this status implies that all messages were <i>sent</i> , but it gives no assurances that any of them were actually <i>delivered</i> .
>0	An error occurred

FILES

\$HOME/.mailrc	personal startup file
\$HOME/mbox	secondary storage file
\$HOME/.Maillock	lock file to prevent multiple writers of system mailbox
/etc/mail/mailx.rc	optional system startup file for mailx only

/etc/mail/Mail.rc
 BSD compatibility system-wide startup file for /usr/ucb/mail and /usr/ucb/Mail

/tmp/R[emqsx]*
 temporary files

/usr/share/lib/mailx/mailx.help*
 help message files

/var/mail/*
 post office directory

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

SEE ALSO `biff(1B)`, `echo(1)`, `ed(1)`, `ex(1)`, `fmt(1)`, `lp(1)`, `ls(1)`, `mail(1)`, `mail(1B)`, `mailcompat(1)`, `more(1)`, `pg(1)`, `sh(1)`, `uucp(1C)`, `vacation(1)`, `vi(1)`, `newaliases(1M)`, `sendmail(1M)`, `aliases(4)`, `passwd(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

NOTES Where *shell-command* is shown as valid, arguments are not always allowed. Experimentation is recommended.

Internal variables imported from the execution environment cannot be unset.

The full internet addressing is not fully supported by `mailx`. The new standards need some time to settle down.

Replies do not always generate correct return addresses. Try resending the errant reply with `onehop` set.

`mailx` does not lock your record file. So, if you use a record file and send two or more messages simultaneously, lines from the messages may be interleaved in the record file.

The format for the `alias` command is a space-separated list of recipients, while the format for an alias in either the `.forward` or `/etc/aliases` is a comma-separated list.

To read mail on a workstation running Solaris 1.x when your mail server is running Solaris 2.x, first execute the `mailcompat(1)` program.

make(1S)

NAME	make – maintain, update, and regenerate related programs and files
SYNOPSIS	<pre>/usr/ccs/bin/make [-d] [-dd] [-D] [-DD] [-e] [-i] [-k] [-n] [-p] [-P] [-q] [-r] [-s] [-S] [-t] [-V] [-f <i>makefile</i>]... [-K <i>statefile</i>]... [<i>target</i>...] [<i>macro</i> = <i>value</i>...] /usr/xpg4/bin/make [-d] [-dd] [-D] [-DD] [-e] [-i] [-k] [-n] [-p] [-P] [-q] [-r] [-s] [-S] [-t] [-V] [-f <i>makefile</i>]... [<i>target</i>...] [<i>macro</i> = <i>value</i>...]</pre>
DESCRIPTION	<p>The make utility executes a list of shell commands associated with each <i>target</i>, typically to create or update a file of the same name. <i>makefile</i> contains entries that describe how to bring a target up to date with respect to those on which it depends, which are called <i>dependencies</i>. Since each dependency is a target, it may have dependencies of its own. Targets, dependencies, and sub-dependencies comprise a tree structure that make traces when deciding whether or not to rebuild a <i>target</i>.</p> <p>The make utility recursively checks each <i>target</i> against its dependencies, beginning with the first target entry in <i>makefile</i> if no <i>target</i> argument is supplied on the command line. If, after processing all of its dependencies, a target file is found either to be missing, or to be older than any of its dependencies, make rebuilds it. Optionally with this version of make, a target can be treated as out-of-date when the commands used to generate it have changed since the last time the target was built.</p> <p>To build a given target, make executes the list of commands, called a <i>rule</i>. This rule may be listed explicitly in the target's makefile entry, or it may be supplied implicitly by make.</p> <p>If no <i>target</i> is specified on the command line, make uses the first target defined in <i>makefile</i>.</p> <p>If a <i>target</i> has no makefile entry, or if its entry has no rule, make attempts to derive a rule by each of the following methods, in turn, until a suitable rule is found. Each method is described under USAGE below.</p> <ul style="list-style-type: none">■ Pattern matching rules.■ Implicit rules, read in from a user-supplied makefile.■ Standard implicit rules (also known as suffix rules), typically read in from the file <code>/usr/share/lib/make/make.rules</code>.■ SCCS retrieval. make retrieves the most recent version from the SCCS history file (if any). See the description of the <code>.SCCS_GET</code>: special-function target for details.■ The rule from the <code>.DEFAULT</code>: target entry, if there is such an entry in the makefile. <p>If there is no makefile entry for a <i>target</i>, if no rule can be derived for building it, and if no file by that name is present, make issues an error message and halts.</p>
OPTIONS	The following options are supported:

-d	Displays the reasons why make chooses to rebuild a target; make displays any and all dependencies that are newer. In addition, make displays options read in from the MAKEFLAGS environment variable.
-dd	Displays the dependency check and processing in vast detail.
-D	Displays the text of the makefiles read in.
-DD	Displays the text of the makefiles, make .rules file, the state file, and all hidden-dependency reports.
-e	Environment variables override assignments within makefiles.
-f <i>makefile</i>	<p>Uses the description file <i>makefile</i>. A '-' as the <i>makefile</i> argument denotes the standard input. The contents of <i>makefile</i>, when present, override the standard set of implicit rules and predefined macros. When more than one '-f <i>makefile</i>' argument pair appears, make uses the concatenation of those files, in order of appearance.</p> <p>When no <i>makefile</i> is specified, /usr/ccs/bin/make tries the following in sequence, except when in POSIX mode (see the .POSIX Special-Function Targets in the USAGE section below):</p> <ul style="list-style-type: none"> ■ If there is a file named <i>makefile</i> in the working directory, make uses that file. If, however, there is an SCCS history file (SCCS/s.<i>makefile</i>) which is newer, make attempts to retrieve and use the most recent version. ■ In the absence of the above file(s), if a file named <i>Makefile</i> is present in the working directory, make attempts to use it. If there is an SCCS history file (SCCS/s.<i>Makefile</i>) that is newer, make attempts to retrieve and use the most recent version. <p>When no <i>makefile</i> is specified, /usr/ccs/bin/make in POSIX mode and /usr/xpg4/bin/make try the following files in sequence:</p> <ul style="list-style-type: none"> ■ ./makefile, ./Makefile ■ s.makefile, SCCS/s.makefile ■ s.Makefile, SCCS/s.Makefile
-i	Ignores error codes returned by commands. Equivalent to the special-function target '.IGNORE:'.
-k	When a nonzero error status is returned by a rule, or when make cannot find a rule, abandons work on the current target, but continues with other dependency branches that do not depend on it.
-K <i>statefile</i>	Uses the state file <i>statefile</i> . A '-' as the <i>statefile</i> argument denotes the standard input. The contents of <i>statefile</i> , when present, override the

make(1S)

	<p>standard set of implicit rules and predefined macros. When more than one '-k <i>statefile</i>' argument pair appears, make uses the concatenation of those files, in order of appearance. (See also .KEEP_STATE and .KEEP_STATE_FILE in the Special-Function Targets section).</p>
-n	No execution mode. Prints commands, but does not execute them. Even lines beginning with an @ are printed. However, if a command line contains a reference to the \$(MAKE) macro, that line is always executed (see the discussion of MAKEFLAGS in Reading Makefiles and the Environment). When in POSIX mode, lines beginning with a "+" are executed.
-p	Prints out the complete set of macro definitions and target descriptions.
-P	Merely reports dependencies, rather than building them.
-q	Question mode. make returns a zero or nonzero status code depending on whether or not the target file is up to date. When in POSIX mode, lines beginning with a "+" are executed.
-r	Does not read in the default makefile /usr/share/lib/make/make.rules.
-s	Silent mode. Does not print command lines before executing them. Equivalent to the special-function target .SILENT:.
-S	Undoes the effect of the -k option. Stops processing when a non-zero exit status is returned by a command.
-t	Touches the target files (bringing them up to date) rather than performing their rules. <i>Warning:</i> This can be <i>dangerous</i> when files are maintained by more than one person. When the .KEEP_STATE: target appears in the makefile, this option updates the state file just as if the rules had been performed. When in POSIX mode, lines beginning with a "+" are executed.
-V	Puts make into SysV mode. Refer to sysv-make(1) for respective details.
OPERANDS	The following operands are supported: <i>target</i> Target names, as defined in USAGE. <i>macro=value</i> Macro definition. This definition overrides any regular definition for the specified macro within the makefile itself, or in the environment. However, this definition can still be overridden by conditional macro assignments.
USAGE	The usage of make is described below:

**Reading Makefiles
and the
Environment**

When `make` first starts, it reads the `MAKEFLAGS` environment variable to obtain any of the following options specified present in its value: `-d`, `-D`, `-e`, `-i`, `-k`, `-n`, `-p`, `-q`, `-r`, `-s`, `-S`, or `-t`. Due to the implementation of POSIX.2 (see POSIX.2(5), the `MAKEFLAGS` values will contain a leading `'-` character. The `make` utility then reads the command line for additional options, which also take effect.

Next, `make` reads in a default makefile that typically contains predefined macro definitions, target entries for implicit rules, and additional rules, such as the rule for retrieving SCCS files. If present, `make` uses the file `make.rules` in the current directory; otherwise it reads the file `/usr/share/lib/make/make.rules`, which contains the standard definitions and rules. Use the directive:

```
include /usr/share/lib/make/make.rules
```

in your local `make.rules` file to include them.

Next, `make` imports variables from the environment (unless the `-e` option is in effect), and treats them as defined macros. Because `make` uses the most recent definition it encounters, a macro definition in the makefile normally overrides an environment variable of the same name. When `-e` is in effect, however, environment variables are read in *after* all makefiles have been read. In that case, the environment variables take precedence over definitions in the makefile.

Next, `make` reads any makefiles you specify with `-f`, or one of `makefile` or `Makefile` as described above and then the state file, in the local directory if it exists. If the makefile contains a `.KEEP_STATE_FILE` target, then it reads the state file that follows the target. Refer to special target `.KEEP_STATE_FILE` for details.

Next (after reading the environment if `-e` is in effect), `make` reads in any macro definitions supplied as command line arguments. These override macro definitions in the makefile and the environment both, but only for the `make` command itself.

`make` exports environment variables, using the most recently defined value. Macro definitions supplied on the command line are not normally exported, unless the macro is also an environment variable.

`make` does not export macros defined in the makefile. If an environment variable is set, and a macro with the same name is defined on the command line, `make` exports its value as defined on the command line. Unless `-e` is in effect, macro definitions within the makefile take precedence over those imported from the environment.

The macros `MAKEFLAGS`, `MAKE`, `SHELL`, `HOST_ARCH`, `HOST_MACH`, and `TARGET_MACH` are special cases. See Special-Purpose Macros below for details.

**Makefile Target
Entries**

A target entry has the following format:

```
target [: | ::] [dependency] . . . [; command] . . .
      [command]
      . . .
```

make(1S)

The first line contains the name of a target, or a space-separated list of target names, terminated with a colon or double colon. If a list of targets is given, this is equivalent to having a separate entry of the same form for each target. The colon(s) may be followed by a *dependency*, or a dependency list. `make` checks this list before building the target. The dependency list may be terminated with a semicolon (;), which in turn can be followed by a single Bourne shell command. Subsequent lines in the target entry begin with a TAB and contain Bourne shell commands. These commands comprise the rule for building the target.

Shell commands may be continued across input lines by escaping the NEWLINE with a backslash (\). The continuing line must also start with a TAB.

To rebuild a target, `make` expands macros, strips off initial TAB characters and either executes the command directly (if it contains no shell metacharacters), or passes each command line to a Bourne shell for execution.

The first *non-empty* line that does not begin with a TAB or '#' begins another target or macro definition.

<i>Global</i>	#	Start a comment. The comment ends at the next NEWLINE. If the '#' follows the TAB in a command line, that line is passed to the shell (which also treats '#' as the start of a comment).
	include <i>filename</i>	If the word <code>include</code> appears as the first seven letters of a line and is followed by a SPACE or TAB, the string that follows is taken as a filename to interpolate at that line. <code>include</code> files can be nested to a depth of no more than about 16. If <i>filename</i> is a macro reference, it is expanded.
<i>Targets and Dependencies</i>	:	Target list terminator. Words following the colon are added to the dependency list for the target or targets. If a target is named in more than one colon-terminated target entry, the dependencies for all its entries are added to form that target's complete dependency list.
	::	Target terminator for alternate dependencies. When used in place of a ':' the double-colon allows a target to be checked and updated with respect to alternate dependency lists. When the target is out-of-date with respect to dependencies listed in the first alternate, it is built according to the rule for that entry. When out-of-date with respect to dependencies in another alternate, it is built according the rule in that other entry. Implicit rules do not apply to double-colon targets; you must supply a rule for each entry. If no dependencies are specified, the rule is always performed.

	<i>target</i> [+ <i>target</i> . . .] :	Target group. The rule in the target entry builds all the indicated targets as a group. It is normally performed only once per make run, but is checked for command dependencies every time a target in the group is encountered in the dependency scan.
	%	Pattern matching wild card metacharacter. Like the '*' shell wild card, '%' matches any string of zero or more characters in a target name or dependency, in the target portion of a conditional macro definition, or within a pattern replacement macro reference. Notice that only one '%' can appear in a target, dependency-name, or pattern-replacement macro reference.
	./ <i>pathname</i>	make ignores the leading './' characters from targets with names given as pathnames relative to "dot," the working directory.
Macros	=	Macro definition. The word to the left of this character is the macro name; words to the right comprise its value. Leading and trailing white space characters are stripped from the value. A word break following the = is implied.
	\$	Macro reference. The following character, or the parenthesized or bracketed string, is interpreted as a macro reference: make expands the reference (including the \$) by replacing it with the macro's value.
	() { }	Macro-reference name delimiters. A parenthesized or bracketed word appended to a \$ is taken as the name of the macro being referred to. Without the delimiters, make recognizes only the first character as the macro name.
	\$\$	A reference to the dollar-sign macro, the value of which is the character '\$'. Used to pass variable expressions beginning with \$ to the shell, to refer to environment variables which are expanded by the shell, or to delay processing of dynamic macros within the dependency list of a target, until that target is actually processed.
	\\$	Escaped dollar-sign character. Interpreted as a literal dollar sign within a rule.
	+=	When used in place of '=', appends a string to a macro definition (must be surrounded by white space, unlike '=').
	:=	Conditional macro assignment. When preceded by a list of targets with explicit target entries, the macro definition that follows takes effect when processing only those targets, and their dependencies.
	:sh =	Define the value of a macro to be the output of a command (see Command Substitutions below).

make(1S)

	<code>:sh</code>	In a macro reference, execute the command stored in the macro, and replace the reference with the output of that command (see <code>Command Substitutions</code> below).
<i>Rules</i>	<code>+</code>	<code>make</code> will always execute the commands preceded by a "+", even when <code>-n</code> is specified.
	<code>-</code>	<code>make</code> ignores any nonzero error code returned by a command line for which the first non-TAB character is a '-'. This character is not passed to the shell as part of the command line. <code>make</code> normally terminates when a command returns nonzero status, unless the <code>-i</code> or <code>-k</code> options, or the <code>.IGNORE:</code> special-function target is in effect.
	<code>@</code>	If the first non-TAB character is a @, <code>make</code> does not print the command line before executing it. This character is not passed to the shell.
	<code>?</code>	Escape command-dependency checking. Command lines starting with this character are not subject to command dependency checking.
	<code>!</code>	Force command-dependency checking. Command-dependency checking is applied to command lines for which it would otherwise be suppressed. This checking is normally suppressed for lines that contain references to the '?' dynamic macro (for example, '\$?').
		When any combination of '+', '-', '@', '?', or '!' appear as the first characters after the TAB, all that are present apply. None are passed to the shell.
Special-Function Targets		When incorporated in a makefile, the following target names perform special-functions:
	<code>.DEFAULT:</code>	If it has an entry in the makefile, the rule for this target is used to process a target when there is no other entry for it, no rule for building it, and no SCCS history file from which to retrieve a current version. <code>make</code> ignores any dependencies for this target.
	<code>.DONE:</code>	If defined in the makefile, <code>make</code> processes this target and its dependencies after all other targets are built. This target is also performed when <code>make</code> halts with an error, unless the <code>.FAILED</code> target is defined.
	<code>.FAILED:</code>	This target, along with its dependencies, is performed instead of <code>.DONE</code> when defined in the makefile and <code>make</code> halts with an error.

<code>.GET_POSIX:</code>	This target contains the rule for retrieving the current version of an SCCS file from its history file in the current working directory. <code>make</code> uses this rule when it is running in POSIX mode.
<code>.IGNORE:</code>	Ignore errors. When this target appears in the makefile, <code>make</code> ignores non-zero error codes returned from commands. When used in POSIX mode, <code>.IGNORE</code> could be followed by target names only, for which the errors will be ignored.
<code>.INIT:</code>	If defined in the makefile, this target and its dependencies are built before any other targets are processed.
<code>.KEEP_STATE:</code>	If this target is in effect, <code>make</code> updates the state file, <code>.make.state</code> , in the current directory. This target also activates command dependencies, and hidden dependency checks. If either the <code>.KEEP_STATE:</code> target appears in the makefile, or the environment variable <code>KEEP_STATE</code> is set (" <code>setenv KEEP_STATE</code> "), <code>make</code> will rebuild everything in order to collect dependency information, even if all the targets were up to date due to previous <code>make</code> runs. See also the ENVIRONMENT VARIABLES section. This target has no effect if used in POSIX mode.
<code>.KEEP_STATE_FILE:</code>	This target has no effect if used in POSIX mode. This target implies <code>.KEEP_STATE</code> . If the target is followed by a filename, <code>make</code> uses it as the state file. If the target is followed by a directory name, <code>make</code> looks for a <code>.make.state</code> file in that directory. If the target is not followed by any name, <code>make</code> looks for <code>.make.state</code> file in the current working directory.
<code>.MAKE_VERSION:</code>	A target-entry of the form: <code>.MAKE_VERSION: VERSION-number</code> enables version checking. If the version of <code>make</code> differs from the version indicated by a string like " <code>VERSION-1.0</code> ", <code>make</code> issues a warning message.
<code>.NO_PARALLEL:</code>	Currently, this target has no effect, it is, however, reserved for future use.
<code>.PARALLEL:</code>	Currently of no effect, but reserved for future use.
<code>.POSIX:</code>	This target enables POSIX mode.
<code>.PRECIOUS:</code>	List of files not to delete. <code>make</code> does not remove any of the files listed as dependencies for this target when

make(1S)

	<p>interrupted. <code>make</code> normally removes the current target when it receives an interrupt. When used in POSIX mode, if the target is not followed by a list of files, all the file are assumed precious.</p>
	<p><code>.SCCS_GET</code>: This target contains the rule for retrieving the current version of an SCCS file from its history file. To suppress automatic retrieval, add an entry for this target with an empty rule to your makefile.</p>
	<p><code>.SCCS_GET_POSIX</code>: This target contains the rule for retrieving the current version of an SCCS file from its history file. <code>make</code> uses this rule when it is running in POSIX mode.</p>
	<p><code>.SILENT</code>: Run silently. When this target appears in the makefile, <code>make</code> does not echo commands before executing them. When used in POSIX mode, it could be followed by target names, and only those will be executed silently.</p>
	<p><code>.SUFFIXES</code>: The suffixes list for selecting implicit rules (see The Suffixes List).</p>
	<p><code>.WAIT</code>: Currently of no effect, but reserved for future use.</p>
<i>Clearing Special Targets</i>	<p>In this version of <code>make</code>, you can clear the definition of the following special targets by supplying entries for them with no dependencies and no rule:</p> <p><code>.DEFAULT</code>, <code>.SCCS_GET</code>, and <code>.SUFFIXES</code></p>
Command Dependencies	<p>When the <code>.KEEP_STATE</code>: target is effective, <code>make</code> checks the command for building a target against the state file. If the command has changed since the last <code>make</code> run, <code>make</code> rebuilds the target.</p>
Hidden Dependencies	<p>When the <code>.KEEP_STATE</code>: target is effective, <code>make</code> reads reports from <code>cpp(1)</code> and other compilation processors for any "hidden" files, such as <code>#include</code> files. If the target is out of date with respect to any of these files, <code>make</code> rebuilds it.</p>
Macros	<p>Entries of the form</p> <p><i>macro=value</i></p> <p>define macros. <i>macro</i> is the name of the macro, and <i>value</i>, which consists of all characters up to a comment character or unescaped <code>NEWLINE</code>, is the value. <code>make</code> strips both leading and trailing white space in accepting the value.</p> <p>Subsequent references to the macro, of the forms: <code>\$(name)</code> or <code>\${name}</code> are replaced by <i>value</i>. The parentheses or brackets can be omitted in a reference to a macro with a single-character name.</p> <p>Macro references can contain references to other macros, in which case nested references are expanded first.</p>

*Suffix Replacement
Macro References*

Substitutions within macros can be made as follows:

```
$(name:string1=string2)
```

where *string1* is either a suffix, or a word to be replaced in the macro definition, and *string2* is the replacement suffix or word. Words in a macro value are separated by SPACE, TAB, and escaped NEWLINE characters.

*Pattern Replacement
Macro References*

Pattern matching replacements can also be applied to macros, with a reference of the form:

```
$(name: op%os= np%ns)
```

where *op* is the existing (old) prefix and *os* is the existing (old) suffix, *np* and *ns* are the new prefix and new suffix, respectively, and the pattern matched by % (a string of zero or more characters), is carried forward from the value being replaced. For example:

```
PROGRAM=fabricate
DEBUG= $(PROGRAM:%=tmp/%-g)
```

sets the value of DEBUG to tmp/fabricate-g.

Notice that pattern replacement macro references cannot be used in the dependency list of a pattern matching rule; the % characters are not evaluated independently. Also, any number of % metacharacters can appear after the equal-sign.

*Appending to a
Macro*

Words can be appended to macro values as follows:

```
macro += word...
```

**Special-Purpose
Macros**

When the MAKEFLAGS variable is present in the environment, make takes options from it, in combination with options entered on the command line. make retains this combined value as the MAKEFLAGS macro, and exports it automatically to each command or shell it invokes.

Notice that flags passed by way of MAKEFLAGS are only displayed when the -d, or -dd options are in effect.

The MAKE macro is another special case. It has the value make by default, and temporarily overrides the -n option for any line in which it is referred to. This allows nested invocations of make written as:

```
$(MAKE) . . .
```

to run recursively, with the -n flag in effect for all commands but make. This lets you use 'make -n' to test an entire hierarchy of makefiles.

For compatibility with the 4.2 BSD make, the MFLAGS macro is set from the MAKEFLAGS variable by prepending a '-'. MFLAGS is not exported automatically.

The SHELL macro, when set to a single-word value such as /usr/bin/csh, indicates the name of an alternate shell to use. The default is /bin/sh. Notice that make executes commands that contain no shell metacharacters itself. Built-in commands,

make(1S)

such as `dirs` in the C shell, are not recognized unless the command line includes a metacharacter (for instance, a semicolon). This macro is neither imported from, nor exported to the environment, regardless of `-e`. To be sure it is set properly, you must define this macro within every makefile that requires it.

The syntax of the `VPATH` macro is:

```
VPATH = [ pathname [ : pathname ] ... ]
```

`VPATH` specifies a list of directories to search for the files, which are targets or dependencies, when `make` is executed. `VPATH` is also used in order to search for the include files mentioned in the particular makefile.

When processing a target or a dependency or an include directive, `make` checks the existence of the file with the same name in the current directory. If the file is found to be missing, `make` will search for this file in the list of directories presented in `VPATH` (like the `PATH` variable in the shell). Unlike the `PATH` variable, `VPATH` is used in order to search for the files with relative pathnames. When `make` attempts to apply implicit rules to the target, it also searches for the dependency files using `VPATH`.

When the file is found using `VPATH`, internal macros `$$`, `@<`, `$$?`, `$$*`, and their alternative forms (with `D` or `F` appended) are set in accordance with the name derived from `VPATH`. For instance, if the target `subdir/foo.o` is found in the directory `/aaa/bbb` using `VPATH`, then the value of the internal macro `$$` for this target will be `/aaa/bbb/subdir/foo.o`.

If a target or a dependency file is found using `VPATH`, then any occurrences of the word that is the same as the target name in the subsequent rules will be replaced with the actual name of the target derived from `VPATH`.

For example:

```
VPATH=./subdir
file.o : file.c
        cc -c file.c -o file.o
```

If `file.c` is found in `./subdir`, then the command

```
cc -c ./subdir/file.c -o file.o
```

will be executed.

The following macros are provided for use with cross-compilation:

<code>HOST_ARCH</code>	The machine architecture of the host system. By default, this is the output of the <code>arch(1)</code> command prepended with <code>'-'</code> . Under normal circumstances, this value should never be altered by the user.
<code>HOST_MACH</code>	The machine architecture of the host system. By default, this is the output of the <code>mach(1)</code> , prepended with <code>'-'</code> . Under normal circumstances, this value should never be altered by the user.

Dynamic Macros	<p>TARGET_ARCH The machine architecture of the target system. By default, the output of <code>mach</code>, prepended with <code>'-'</code>.</p> <p>There are several dynamically maintained macros that are useful as abbreviations within rules. They are shown here as references; if you were to define them, <code>make</code> would simply override the definition.</p> <p><code>\$*</code> The basename of the current target, derived as if selected for use with an implicit rule.</p> <p><code>\$<</code> The name of a dependency file, derived as if selected for use with an implicit rule.</p> <p><code>\$@</code> The name of the current target. This is the only dynamic macro whose value is strictly determined when used in a dependency list. (In which case it takes the form <code>'\$\$@'</code>.)</p> <p><code>\$?</code> The list of dependencies that are newer than the target. Command-dependency checking is automatically suppressed for lines that contain this macro, just as if the command had been prefixed with a <code>'?'</code>. See the description of <code>'?'</code>, under <i>Special Character Rules</i> above. You can force this check with the <code>!</code> command-line prefix.</p> <p><code>\$%</code> The name of the library member being processed. (See <i>Library Maintenance</i> below.)</p> <p>To refer to the <code>\$@</code> dynamic macro within a dependency list, precede the reference with an additional <code>'\$'</code> character (as in, <code>'\$\$@'</code>). Because <code>make</code> assigns <code>\$<</code> and <code>\$*</code> as it would for implicit rules (according to the suffixes list and the directory contents), they may be unreliable when used within explicit target entries.</p> <p>These macros can be modified to apply either to the filename part, or the directory part of the strings they stand for, by adding an upper case <code>F</code> or <code>D</code>, respectively (and enclosing the resulting name in parentheses or braces). Thus, <code>'\$ (@D)'</code> refers to the directory part of the string <code>'\$@'</code>; if there is no directory part, <code>'.'</code> is assigned. <code>\$ (@F)</code> refers to the filename part.</p>
Conditional Macro Definitions	<p>A macro definition of the form:</p> <pre>target-list := macro = value</pre> <p>indicates that when processing any of the targets listed <i>and their dependencies</i>, <code>macro</code> is to be set to the <code>value</code> supplied. Notice that if a conditional macro is referred to in a dependency list, the <code>\$</code> must be delayed (use <code>\$\$</code> instead). Also, <code>target-list</code> may contain a <code>%</code> pattern, in which case the macro will be conditionally defined for all targets encountered that match the pattern. A pattern replacement reference can be used within the <code>value</code>.</p> <p>You can temporarily append to a macro's value with a conditional definition of the form:</p> <pre>target-list := macro += value</pre>

make(1S)

Predefined Macros

make supplies the macros shown in the table that follows for compilers and their options, host architectures, and other commands. Unless these macros are read in as environment variables, their values are not exported by make. If you run make with any of these set in the environment, it is a good idea to add commentary to the makefile to indicate what value each is expected to take. If `-r` is in effect, make does not read the default makefile (`./make.rules` or `/usr/share/lib/make/make.rules`) in which these macro definitions are supplied.

Implicit Rules When a target has no entry in the makefile, `make` attempts to determine its class (if any) and apply the rule for that class. An implicit rule describes how to build any target of a given class, from an associated dependency file. The class of a target can be determined either by a pattern, or by a suffix; the corresponding dependency file (with the same basename) from which such a target might be built. In addition to a predefined set of implicit rules, `make` allows you to define your own, either by pattern, or by suffix.

Pattern Matching Rules

A target entry of the form:

```
tp%ts: dp%ds
      rule
```

is a pattern matching rule, in which *tp* is a target prefix, *ts* is a target suffix, *dp* is a dependency prefix, and *ds* is a dependency suffix (any of which may be null). The '%' stands for a basename of zero or more characters that is matched in the target, and is used to construct the name of a dependency. When `make` encounters a match in its search for an implicit rule, it uses the rule in that target entry to build the target from the dependency file. Pattern-matching implicit rules typically make use of the `$$` and `$(` dynamic macros as placeholders for the target and dependency names. Other, regular dependencies may occur in the dependency list; however, none of the regular dependencies may contain '%'. An entry of the form:

```
tp%ts: [dependency... ] dp%ds [dependency... ]
      rule
```

is a valid pattern matching rule.

Suffix Rules

When no pattern matching rule applies, `make` checks the target name to see if it ends with a suffix in the known suffixes list. If so, `make` checks for any suffix rules, as well as a dependency file with same root and another recognized suffix, from which to build it.

The target entry for a suffix rule takes the form:

```
DsTs: rule
```

where *Ts* is the suffix of the target, *Ds* is the suffix of the dependency file, and *rule* is the rule for building a target in the class. Both *Ds* and *Ts* must appear in the suffixes list. (A suffix need not begin with a '.' to be recognized.)

A suffix rule with only one suffix describes how to build a target having a null (or no) suffix from a dependency file with the indicated suffix. For instance, the `.c` rule could be used to build an executable program named `file` from a C source file named `'file.c'`. If a target with a null suffix has an explicit dependency, `make` omits the search for a suffix rule.

make(1S)

Implicit Rule Name	Command Line
	<pre>\$(CC) \$(CFLAGS) -c y.tab.c rm -f y.tab.c mv y.tab.o \$@</pre>

make reads in the standard set of implicit rules from the file `/usr/share/lib/make/make.rules`, unless `-r` is in effect, or there is a `make.rules` file in the local directory that does not include that file.

The Suffixes List

The suffixes list is given as the list of dependencies for the `.SUFFIXES:` special-function target. The default list is contained in the `SUFFIXES` macro (See *Table of Predefined Macros* for the standard list of suffixes). You can define additional `.SUFFIXES: targets`; a `.SUFFIXES` target with no dependencies clears the list of suffixes. Order is significant within the list; make selects a rule that corresponds to the target's suffix and the first dependency-file suffix found in the list. To place suffixes at the head of the list, clear the list and replace it with the new suffixes, followed by the default list:

```
.SUFFIXES:  
.SUFFIXES: suffixes $(SUFFIXES)
```

A tilde (`~`) indicates that if a dependency file with the indicated suffix (minus the `~`) is under SCCS its most recent version should be retrieved, if necessary, before the target is processed.

Library Maintenance

A target name of the form:

```
lib (member ...)
```

refers to a member, or a space-separated list of members, in an `ar(1)` library.

The dependency of the library member on the corresponding file must be given as an explicit entry in the makefile. This can be handled by a pattern matching rule of the form:

```
lib (%.s) : %.s
```

where `.s` is the suffix of the member; this suffix is typically `.o` for object libraries.

A target name of the form:

```
lib ( symbol )
```

refers to the member of a randomized object library that defines the entry point named *symbol*.

Command Execution	<p>Command lines are executed one at a time, <i>each by its own process or shell</i>. Shell commands, notably <code>cd</code>, are ineffectual across an unescaped <code>NEWLINE</code> in the makefile. A line is printed (after macro expansion) just before being executed. This is suppressed if it starts with a <code>'@'</code>, if there is a <code>'SILENT:'</code> entry in the makefile, or if <code>make</code> is run with the <code>-s</code> option. Although the <code>-n</code> option specifies printing without execution, lines containing the macro <code>\$(MAKE)</code> are executed regardless, and lines containing the <code>@</code> special character are printed. The <code>-t</code> (touch) option updates the modification date of a file without executing any rules. This can be dangerous when sources are maintained by more than one person.</p> <p><code>make</code> invokes the shell with the <code>-e</code> (exit-on-errors) argument. Thus, with semicolon-separated command sequences, execution of the later commands depends on the success of the former. This behavior can be overridden by starting the command line with a <code>'-'</code>, or by writing a shell script that returns a non-zero status only as it finds appropriate.</p>
Bourne Shell Constructs	<p>To use the Bourne shell <code>if</code> control structure for branching, use a command line of the form:</p> <pre>if expression ; \ then command ; \ ... ; \ else command ; \ ... ; \ fi</pre> <p>Although composed of several input lines, the escaped <code>NEWLINE</code> characters insure that <code>make</code> treats them all as one (shell) command line.</p> <p>To use the Bourne shell <code>for</code> control structure for loops, use a command line of the form:</p> <pre>for var in list ; \ do command ; \ ... ; \done</pre> <p>To refer to a shell variable, use a double-dollar-sign (<code>\$\$</code>). This prevents expansion of the dollar-sign by <code>make</code>.</p>
Command Substitutions	<p>To incorporate the standard output of a shell command in a macro, use a definition of the form:</p> <pre>MACRO :sh =command</pre> <p>The command is executed only once, standard error output is discarded, and <code>NEWLINE</code> characters are replaced with <code>SPACES</code>. If the command has a non-zero exit status, <code>make</code> halts with an error.</p> <p>To capture the output of a shell command in a macro reference, use a reference of the form:</p> <pre>\$(MACRO :sh)</pre>

make(1S)

where *MACRO* is the name of a macro containing a valid Bourne shell command line. In this case, the command is executed whenever the reference is evaluated. As with shell command substitutions, the reference is replaced with the standard output of the command. If the command has a non-zero exit status, make halts with an error.

In contrast to commands in rules, the command is not subject for macro substitution; therefore, a dollar sign (\$) need not be replaced with a double dollar sign (\$\$).

Signals

INT, SIGTERM, and QUIT signals received from the keyboard halt make and remove the target file being processed unless that target is in the dependency list for .PRECIOUS:.

EXAMPLES

EXAMPLE 1 Defining dependencies

This makefile says that *pgm* depends on two files *a.o* and *b.o*, and that they in turn depend on their corresponding source files (*a.c* and *b.c*) along with a common file *incl.h*:

```
pgm: a.o b.o
    $(LINK.c) -o $@a.o b.o
a.o: incl.h a.c
    cc -c a.c
b.o: incl.h b.c
    cc -c b.c
```

EXAMPLE 2 Using implicit rules

The following makefile uses implicit rules to express the same dependencies:

```
pgm: a.o b.o
    cc a.o b.o -o pgm
a.o b.o: incl.h
```

ENVIRONMENT VARIABLES

See *environ(5)* for descriptions of the following environment variables that affect the execution of make: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

KEEP_STATE This environment variable has the same effect as the .KEEP_STATE: special-function target. It enables command dependencies, hidden dependencies and writing of the state file.

USE_SVR4_MAKE This environment variable causes make to invoke the generic System V version of make (/usr/ccs/lib/svr4.make). See *sysv-make(1)*.

MAKEFLAGS This variable is interpreted as a character string representing a series of option characters to be used as the default options. The implementation will accept both of the following formats (but need not accept them when intermixed):

1. The characters are option letters without the leading hyphens or blank character separation used on a command line.
2. The characters are formatted in a manner similar to a portion of the `make` command line: options are preceded by hyphens and blank-character-separated. The `macro=name` macro definition operands can also be included. The difference between the contents of `MAKEFLAGS` and the command line is that the contents of the variable will not be subjected to the word expansions (see `wordexp(3C)`) associated with parsing the command line values.

When the command-line options `-f` or `-p` are used, they will take effect regardless of whether they also appear in `MAKEFLAGS`. If they otherwise appear in `MAKEFLAGS`, the result is undefined.

The `MAKEFLAGS` variable will be accessed from the environment before the makefile is read. At that time, all of the options (except `-f` and `-p`) and command-line macros not already included in `MAKEFLAGS` are added to the `MAKEFLAGS` macro. The `MAKEFLAGS` macro will be passed into the environment as an environment variable for all child processes. If the `MAKEFLAGS` macro is subsequently set by the makefile, it replaces the `MAKEFLAGS` variable currently found in the environment.

PROJECTDIR

Provides a directory to be used to search for SCCS files not found in the current directory. In all of the following cases, the search for SCCS files is made in the directory `SCCS` in the identified directory. If the value of `PROJECTDIR` begins with a slash, it shall be considered an absolute pathname. Otherwise, the value of `PROJECTDIR` is treated as a user name and that user's initial working directory shall be examined for a subdirectory `src` or `source`. If such a directory is found, it shall be used. Otherwise, the value is used as a relative pathname.

If `PROJECTDIR` is not set or has a null value, the search for SCCS files shall be made in the directory `SCCS` in the current directory. The setting of `PROJECTDIR` affects all files listed in the remainder of this utility description for files with a component named `SCCS`.

make(1S)

EXIT STATUS When the `-q` option is specified, the make utility will exit with one of the following values:

- 0 Successful completion.
- 1 The target was not up-to-date.
- >1 An error occurred.

When the `-q` option is not specified, the make utility will exit with one of the following values:

- 0 Successful completion
- >0 An error occurred

FILES

makefile
 Makefile
 current version(s) of make description file

s.makefile
 s.Makefile
 SCCS history files for the above makefile(s) in the current directory

SCCS/s.makefile
 SCCS/s.Makefile
 SCCS history files for the above makefile(s)

make.rules
 default file for user-defined targets, macros, and implicit rules

/usr/share/lib/make/make.rules
 makefile for standard implicit rules and macros (not read if make.rules is)

.make.state
 state file in the local directory

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

Solaris Advanced User's Guide

DIAGNOSTICS

Don't know how to make target '*target*'

There is no makefile entry for *target*, and none of make's implicit rules apply (there is no dependency file with a suffix in the suffixes list, or the target's suffix is not in the list).

*** *target* removed.

make was interrupted while building *target*. Rather than leaving a partially-completed version that is newer than its dependencies, make removes the file named *target*.

*** *target* not removed.

make was interrupted while building *target* and *target* was not present in the directory.

*** *target* could not be removed, *reason*

make was interrupted while building *target*, which was not removed for the indicated reason.

Read of include file '*file*' failed

The makefile indicated in an include directive was not found, or was inaccessible.

Loop detected when expanding macro value '*macro*'

A reference to the macro being defined was found in the definition.

Could not write state file '*file*'

You used the .KEEP_STATE: target, but do not have write permission on the state file.

*** Error code *n*

The previous shell command returned a nonzero error code.

*** *signal message*

The previous shell command was aborted due to a signal. If '- core dumped' appears after the message, a core file was created.

Conditional macro conflict encountered

Displayed only when -d is in effect, this message indicates that two or more parallel targets currently being processed depend on a target which is built differently for each by virtue of conditional macros. Since the target cannot simultaneously satisfy both dependency relationships, it is conflicted.

BUGS

Some commands return nonzero status inappropriately; to overcome this difficulty, prefix the offending command line in the rule with a '-'

Filenames with the characters '=', ':', or '@', do not work.

You cannot build `file.o` from `lib(file.o)`.

Options supplied by MAKEFLAGS should be reported for nested make commands. Use the -d option to find out what options the nested command picks up from MAKEFLAGS.

make(1S)

This version of make is incompatible in certain respects with previous versions:

- The `-d` option output is much briefer in this version. `-dd` now produces the equivalent voluminous output.
- make attempts to derive values for the dynamic macros `'$*'`, `'$<'`, and `'$?'`, while processing explicit targets. It uses the same method as for implicit rules; in some cases this can lead either to unexpected values, or to an empty value being assigned. (Actually, this was true for earlier versions as well, even though the documentation stated otherwise.)
- make no longer searches for SCCS history "(s)" files.
- Suffix replacement in macro references are now applied after the macro is expanded.

There is no guarantee that makefiles created for this version of make will work with earlier versions.

If there is no `make.rules` file in the current directory, and the file `/usr/share/lib/make/make.rules` is missing, make stops before processing any targets. To force make to run anyway, create an empty `make.rules` file in the current directory.

Once a dependency is made, make assumes the dependency file is present for the remainder of the run. If a rule subsequently removes that file and future targets depend on its existence, unexpected errors may result.

When hidden dependency checking is in effect, the `$?` macro's value includes the names of hidden dependencies. This can lead to improper filename arguments to commands when `$?` is used in a rule.

Pattern replacement macro references cannot be used in the dependency list of a pattern matching rule.

Unlike previous versions, this version of make strips a leading `'./'` from the value of the `'$@'` dynamic macro.

With automatic SCCS retrieval, this version of make does not support tilde suffix rules.

The only dynamic macro whose value is strictly determined when used in a dependency list is `$@` (takes the form `'$$@'`).

make invokes the shell with the `-e` argument. This cannot be inferred from the syntax of the rule alone.

NAME	man – find and display reference manual pages
SYNOPSIS	<pre>man [-] [-adFlrt] [-M path] [-T macro-package] [-s section] name... man [-M path] -k keyword... man [-M path] -f file...</pre>
DESCRIPTION	The man command displays information from the reference manuals. It displays complete manual pages that you select by <i>name</i> , or one-line summaries selected either by <i>keyword</i> (-k), or by the name of an associated file (-f). If no manual page is located, man prints an error message.
Source Format	Reference Manual pages are marked up with either nroff (see nroff(1)) or SGML (Standard Generalized Markup Language) tags (see sgm1(5)). The man command recognizes the type of markup and processes the file accordingly. The various source files are kept in separate directories depending on the type of markup.
Location of Manual Pages	<p>The online Reference Manual page directories are conventionally located in /usr/share/man. The nroff sources are located in the /usr/share/man/man* directories. The SGML sources are located in the /usr/share/man/sman* directories. Each directory corresponds to a section of the manual. Since these directories are optionally installed, they may not reside on your host. You may have to mount /usr/share/man from a host on which they do reside.</p> <p>If there are preformatted, up-to-date versions in the corresponding cat* or fmt* directories, man simply displays or prints those versions. If the preformatted version of interest is out of date or missing, man reformats it prior to display and will store the preformatted version if cat* or fmt* is writable. The windex database is not updated. See catman(1M). If directories for the preformatted versions are not provided, man reformats a page whenever it is requested. man uses a temporary file to store the formatted text during display.</p> <p>If the standard output is not a terminal, or if the '-' flag is given, man pipes its output through cat(1). Otherwise, man pipes its output through more(1) to handle paging and underlining on the screen.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Shows all manual pages matching <i>name</i> within the MANPATH search path. Manual pages are displayed in the order found. -d Debugs. Displays what a section-specifier evaluates to, method used for searching, and paths searched by man. -f <i>file ...</i> man attempts to locate manual pages related to any of the given <i>files</i>. It strips the leading path name components from each <i>file</i>, and then prints one-line summaries containing the resulting basename or names. This option also uses the windex database. -F Forces man to search all directories specified by MANPATH or the man.cf file, rather than using the windex lookup database. This

man(1)

	<p>option is useful if the database is not up to date and it has been made the default behavior of the man command. The option therefore does not have to be invoked and is documented here for reference only.</p>
-k <i>keyword</i> ...	Prints out one-line summaries from the <code>windex</code> database (table of contents) that contain any of the given <i>keywords</i> . The <code>windex</code> database is created using <code>catman(1M)</code> .
-l	Lists all manual pages found matching <i>name</i> within the search path.
-M <i>path</i>	Specifies an alternate search path for manual pages. <i>path</i> is a colon-separated list of directories that contain manual page directory subtrees. For example, if <i>path</i> is <code>/usr/share/man:/usr/local/man</code> , man searches for <i>name</i> in the standard location, and then <code>/usr/local/man</code> . When used with the <code>-k</code> or <code>-f</code> options, the <code>-M</code> option must appear first. Each directory in the <i>path</i> is assumed to contain subdirectories of the form <code>man*</code> or <code>sman*</code> , one for each section. This option overrides the <code>MANPATH</code> environment variable.
-r	Reformats the manual page, but does not display it. This replaces the <code>man - -t name</code> combination.
-s <i>section</i> ...	Specifies sections of the manual for man to search. The directories searched for <i>name</i> are limited to those specified by <i>section</i> . <i>section</i> can be a numerical digit, perhaps followed by one or more letters to match the desired section of the manual, for example, <code>"3libc"</code> . Also, <i>section</i> can be a word, for example, <code>local</code> , <code>new</code> , <code>old</code> , <code>public</code> . <i>section</i> can also be a letter. To specify multiple sections, separate each section with a comma. This option overrides the <code>MANPATH</code> environment variable and the <code>man.cf</code> file. See <code>Search Path</code> below for an explanation of how man conducts its search.
-t	man arranges for the specified manual pages to be <code>troffed</code> to a suitable raster output device (see <code>troff(1)</code>). If both the <code>-</code> and <code>-t</code> flags are given, man updates the <code>troffed</code> versions of each named <i>name</i> (if necessary), but does not display them.
-T <i>macro-package</i>	Formats manual pages using <i>macro-package</i> rather than the standard <code>-man</code> macros defined in <code>/usr/share/lib/tmac/an</code> . See <code>Search Path</code> under <code>USAGE</code> for a complete explanation of the default search path order.
OPERANDS	The following operand is supported: <i>name</i> A keyword or the name of a standard utility.
USAGE	The usage of man is described below:

Manual Page Sections	<p>Entries in the reference manuals are organized into <i>sections</i>. A section name consists of a major section name, typically a single digit, optionally followed by a subsection name, typically one or more letters. An unadorned major section name, for example, "9", does not act as an abbreviation for the subsections of that name, such as "9e", "9f", or "9s". That is, each subsection must be searched separately by <code>man -s</code>. Each section contains descriptions apropos to a particular reference category, with subsections refining these distinctions. See the <code>intro</code> manual pages for an explanation of the classification used in this release.</p>				
Search Path	<p>Before searching for a given <i>name</i>, <code>man</code> constructs a list of candidate directories and sections. <code>man</code> searches for <i>name</i> in the directories specified by the <code>MANPATH</code> environment variable. If this variable is not set, <code>/usr/share/man</code> is searched by default.</p> <p>Within the manual page directories, <code>man</code> confines its search to the sections specified in the following order:</p> <ul style="list-style-type: none"> ■ <i>sections</i> specified on the command line with the <code>-s</code> option ■ <i>sections</i> embedded in the <code>MANPATH</code> environment variable ■ <i>sections</i> specified in the <code>man.cf</code> file for each directory specified in the <code>MANPATH</code> environment variable <p>If none of the above exist, <code>man</code> searches each directory in the manual page path, and displays the first matching manual page found.</p> <p>The <code>man.cf</code> file has the following format:</p> <pre>MANSECTS=section [, section] . . .</pre> <p>Lines beginning with '#' and blank lines are considered comments, and are ignored. Each directory specified in <code>MANPATH</code> can contain a manual page configuration file, specifying the default search order for that directory.</p>				
Formatting Manual Pages	<p>Manual pages are marked up in <code>nroff(1)</code> or <code>sgml(5)</code>. <code>Nroff</code> manual pages are processed by <code>nroff(1)</code> or <code>troff(1)</code> with the <code>-man</code> macro package. Please refer to <code>man(5)</code> for information on macro usage. SGML—tagged manual pages are processed by an SGML parser and passed to the formatter.</p>				
Preprocessing Nroff Manual Pages	<p>When formatting an <code>nroff</code> manual page, <code>man</code> examines the first line to determine whether it requires special processing. If the first line is a string of the form:</p> <pre>'\ " X</pre> <p>where <i>X</i> is separated from the "'" by a single <code>SPACE</code> and consists of any combination of characters in the following list, <code>man</code> pipes its input to <code>troff(1)</code> or <code>nroff(1)</code> through the corresponding preprocessors.</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">e</td> <td><code>eqn(1)</code>, or <code>neqn</code> for <code>nroff</code></td> </tr> <tr> <td>r</td> <td><code>refer(1)</code></td> </tr> </table>	e	<code>eqn(1)</code> , or <code>neqn</code> for <code>nroff</code>	r	<code>refer(1)</code>
e	<code>eqn(1)</code> , or <code>neqn</code> for <code>nroff</code>				
r	<code>refer(1)</code>				

man(1)

	<p>t tbl(1)</p> <p>v vgrind(1)</p>
	<p>If eqn or neqn is invoked, it will automatically read the file /usr/pub/eqnchar (see eqnchar(5)). If nroff(1) is invoked, col(1) is automatically used.</p>
Referring to Other nroff Manual Pages	<p>If the first line of the nroff manual page is a reference to another manual page entry fitting the pattern:</p> <pre>.so man*/sourcefile</pre> <p>man processes the indicated file in place of the current one. The reference must be expressed as a path name relative to the root of the manual page directory subtree.</p> <p>When the second or any subsequent line starts with .so, man ignores it; troff(1) or nroff(1) processes the request in the usual manner.</p>
Processing SGML Manual Pages	<p>Manual pages are identified as being marked up in SGML by the presence of the string <!DOCTYPE. If the file also contains the string SHADOW_PAGE, the file refers to another manual page for the content. The reference is made with a file entity reference to the manual page that contains the text. This is similar to the .so mechanism used in the nroff formatted man pages.</p>
ENVIRONMENT VARIABLES	<p>See environ(5) for descriptions of the following environment variables that affect the execution of man: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.</p> <p>MANPATH A colon-separated list of directories; each directory can be followed by a comma-separated list of sections. If set, its value overrides /usr/share/man as the default directory search path, and the man.cf file as the default section search path. The -M and -s flags, in turn, override these values.)</p> <p>PAGER A program to use for interactively delivering man's output to the screen. If not set, 'more -s' is used. See more(1).</p> <p>TCAT The name of the program to use to display troffed manual pages.</p> <p>TROFF The name of the formatter to use when the -t flag is given. If not set, troff(1) is used.</p>
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>>0 An error occurred.</p>
FILES	<p>/usr/share/man Root of the standard manual page directory subtree</p> <p>/usr/share/man/man?/* Unformatted nroff manual entries</p>

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc
CSI	Enabled (see NOTES)
Interface Stability	Standard

SEE ALSO `apropos(1)`, `cat(1)`, `col(1)`, `eqn(1)`, `more(1)`, `nroff(1)`, `refer(1)`, `tbl(1)`, `troff(1)`, `vgrind(1)`, `whatis(1)`, `catman(1M)`, `attributes(5)`, `environ(5)`, `eqnchar(5)`, `man(5)`, `sgml(5)`, `standards(5)`

NOTES The `-f` and `-k` options use the `windex` database, which is created by `catman(1M)`.

The `man` command is CSI-capable. However, some utilities invoked by the `man` command, namely, `troff`, `eqn`, `neqn`, `refer`, `tbl`, and `vgrind`, are not verified to be CSI-capable. Because of this, the `man` command with the `-t` option may not handle non-EUC data. Also, using the `man` command to display man pages that require special processing through `eqn`, `neqn`, `refer`, `tbl`, or `vgrind` may not be CSI-capable.

man(1)

BUGS | The manual is supposed to be reproducible either on a phototypesetter or on an ASCII terminal. However, on a terminal some information (indicated by font changes, for instance) is lost.

Some dumb terminals cannot process the vertical motions produced by the `e` (see `eqn(1)`) preprocessing flag. To prevent garbled output on these terminals, when you use `e`, also use `t`, to invoke `col(1)` implicitly. This workaround has the disadvantage of eliminating superscripts and subscripts, even on those terminals that can display them. Control-q will clear a terminal that gets confused by `eqn(1)` output.

NAME	mconnect – connect to SMTP mail server socket
SYNOPSIS	mconnect [-p <i>port</i>] [-r] [<i>hostname</i>]
DESCRIPTION	The mconnect utility opens a connection to the mail server on a given host, so that it can be tested independently of all other mail software. If no host is given, the connection is made to the local host. Servers expect to speak the Simple Mail Transfer Protocol (SMTP) on this connection. Exit by typing the quit command. Typing EOF sends an end of file to the server. An interrupt closes the connection immediately and exits.
OPTIONS	The following options are supported: <p>-p <i>port</i> Specify the port number instead of the default SMTP port (number 25) as the next argument.</p> <p>-r "Raw" mode: disable the default line buffering and input handling. This produces an effect similar to telnet(1) to port number 25.</p>
OPERANDS	The following operand is supported: <p><i>hostname</i> The name of a given host.</p>
USAGE	The mconnect command is IPv6-enabled. See ip6(7P).
FILES	/etc/mail/sendmail.hf help file for SMTP commands
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

mcs(1)

NAME	mcs – manipulate the comment section of an object file
SYNOPSIS	<code>/usr/ccs/bin/mcs</code> { <code>-c</code> <code>-d</code> <code>-p</code> <code>-v</code> <code>-a string</code> <code>-n name...</code> } <i>file...</i>
DESCRIPTION	<p>The <code>mcs</code> command is used to manipulate a section, by default the <code>.comment</code> section, in an ELF object file. It is used to add to, delete, print, and compress the contents of a section in an ELF object file, and print only the contents of a section in a COFF object file. <code>mcs</code> cannot add, delete, or compress the contents of a section that is contained within a segment.</p> <p>If the input file is an archive (see <code>ar(3HEAD)</code>), the archive is treated as a set of individual files. For example, if the <code>-a</code> option is specified, the string is appended to the comment section of each ELF object file in the archive; if the archive member is not an ELF object file, then it is left unchanged.</p> <p><code>mcs</code> must be given one or more of the options described below. It applies, in order, each of the specified options to each file.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-a string</code> Appends <i>string</i> to the comment section of the ELF object files. If <i>string</i> contains embedded blanks, it must be enclosed in quotation marks.<code>-c</code> Compresses the contents of the comment section of the ELF object files. All duplicate entries are removed. The ordering of the remaining entries is not disturbed.<code>-d</code> Deletes the contents of the comment section from the ELF object files. The section header for the comment section is also removed.<code>-n name</code> Specifies the name of the comment section to access if other than <code>.comment</code>. By default, <code>mcs</code> deals with the section named <code>.comment</code>. This option can be used to specify another section. <code>mcs</code> can take multiple <code>-n</code> options to allow for specification of multiple section comments.<code>-p</code> Prints the contents of the comment section on the standard output. Each section printed is tagged by the name of the file from which it was extracted, using the format <i>file</i> [<i>member_name</i>] : for archive files and <i>file</i>: for other files.<code>-v</code> Prints on standard error the version number of <code>mcs</code>.
EXAMPLES	<p>EXAMPLE 1 Printing a file's comment section</p> <p>The following entry</p> <pre>example% /usr/ccs/bin/mcs -p elf.fileprints the comment section of the file elf.file.</pre>

EXAMPLE 2 Appending a string to a comment section

The following entry

```
example% /usr/ccs/bin/mcs -a xyz elf.file appends string xyz to elf.file's
comment section.
```

FILES /tmp/mcs* temporary files

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

SEE ALSO `ar(1)`, `as(1)`, `ld(1)`, `elf(3ELF)`, `tmpnam(3C)`, `a.out(4)`, `ar(3HEAD)`, `attributes(5)`

NOTES When `mcs` deletes a section using the `-d` option, it tries to bind together sections of type `SHT_REL` and target sections pointed to by the `sh_info` section header field. If one is to be deleted, `mcs` attempts to delete the other of the pair.

mdb(1)

NAME	mdb – modular debugger
SYNOPSIS	mdb [-fkmwyAFMS] [\pm o <i>option</i>] [-p <i>pid</i>] [-s <i>distance</i>] [-I <i>path</i>] [-L <i>path</i>] [-P <i>prompt</i>] [-R <i>root</i>] [-V <i>dis-version</i>] [object [core] core <i>suffix</i>]
Introduction	<p>The mdb utility is an extensible utility for low-level debugging and editing of the live operating system, operating system crash dumps, user processes, user process core dumps, and object files. For a more detailed description of mdb features, refer to the manual, <i>Solaris Modular Debugger Guide</i>.</p> <p>Debugging is the process of analyzing the execution and state of a software program in order to remove defects. Traditional debugging tools provide facilities for execution control so that programmers can re-execute programs in a controlled environment and display the current state of program data or evaluate expressions in the source language used to develop the program.</p> <p>Unfortunately, these techniques are often inappropriate for debugging complex software systems such as an operating system, where bugs may not be reproducible and program state is massive and distributed, for programs that are highly optimized, have had their debug information removed, or are themselves low-level debugging tools, or for customer situations where the developer can only access post-mortem information.</p> <p>mdb provides a completely customizable environment for debugging these programs and scenarios, including a dynamic module facility that programmers can use to implement their own debugging commands to perform program-specific analysis. Each mdb module can be used to examine the program in several different contexts, including live and post-mortem.</p>
Definitions	<p>The <i>target</i> is the program being inspected by the debugger. mdb currently provides support for the following types of targets: user processes, user process core files, the live operating system (via /dev/kmem and /dev/ksyms), operating system crash dumps, user process images recorded inside an operating system crash dump, ELF object files, and raw binary files. Each target exports a standard set of properties, including one or more address spaces, one or more symbol tables, a set of load objects, and a set of threads that can be examined using the debugger commands described below.</p> <p>A debugger command, or <i>dcmd</i> (pronounced dee-command) in mdb terminology, is a routine in the debugger that can access any of the properties of the current target. mdb parses commands from standard input, and then executes the corresponding dcmds. Each dcmd can also accept a list of string or numerical arguments, as shown in the syntax description below. mdb contains a set of built-in dcmds, described below, that are always available. You can also extend the capabilities of mdb itself by writing your own dcmds, as described in the <i>Solaris Modular Debugger Guide</i>.</p>

A *walker* is a set of routines that describe how to walk, or iterate, through the elements of a particular program data structure. A walker encapsulates the data structure's implementation from dcmds and from mdb itself. You can use walkers interactively, or use them as a primitive to build other dcmds or walkers. As with dcmds, you can extend mdb by implementing your own walkers as part of a debugger module.

A debugger module, or *dmod* (pronounced dee-mod), is a dynamically loaded library containing a set of dcmds and walkers. During initialization, mdb will attempt to load dmods corresponding to the load objects present in the target. You can subsequently load or unload dmods at any time while running mdb. mdb ships with a set of standard dmods for debugging the Solaris kernel. The *Solaris Modular Debugger Guide* contains more information on developing your own debugger modules.

A *macro file* is a text file containing a set of commands to execute. Macro files are typically used to automate the process of displaying a simple data structure. mdb provides complete backward compatibility for the execution of macro files written for adb(1), and the Solaris installation includes a set of macro files for debugging the Solaris kernel that may be used with either tool.

Syntax

The debugger processes commands from standard input. If standard input is a terminal, mdb provides terminal editing capabilities. mdb can also process commands from macro files and from dcmd pipelines, described below. The language syntax is designed around the concept of computing the value of an expression (typically a memory address in the target), and then applying a dcmd to that address. The current address location is referred to as *dot*, and its value is referenced using `."`.

A *metacharacter* is one of the following characters:

```
[ ] | ! / \ ? = > $ : ;
      NEWLINE SPACE TAB
```

A *blank* is a TAB or a SPACE. A *word* is a sequence of characters separated by one or more non-quoted metacharacters. Some of the metacharacters only function as delimiters in certain contexts, as described below. An *identifier* is a sequence of letters, digits, underscores, periods, or backquotes beginning with a letter, underscore, or period. Identifiers are used as the names of symbols, variables, dcmds, and walkers. Commands are delimited by a NEWLINE or semicolon (;).

A dcmd is denoted by one of the following words or metacharacters:

```
/ \ ? = > $character :character ::identifier
```

dcmds named by metacharacters or prefixed by a single \$ or : are provided as built-in operators, and implement complete compatibility with the command set of the legacy adb(1) utility. Once a dcmd has been parsed, the /, \, ?, =, >, \$, and : characters are no longer recognized as metacharacters until the termination of the argument list.

mdb(1)

A *simple-command* is a `dcmd` followed by a sequence of zero or more blank-separated words. The words are passed as arguments to the invoked `dcmd`, except as specified under `Quoting` and `Arithmetic Expansion` below. Each `dcmd` returns an exit status that indicates it was either successful, failed, or was invoked with invalid arguments.

A *pipeline* is a sequence of one or more simple commands separated by `|`. Unlike the shell, `dcmds` in `mdb` pipelines are not executed as separate processes. After the pipeline has been parsed, each `dcmd` is invoked in order from left to right. Each `dcmd`'s output is processed and stored as described under `dcmd Pipelines` below. Once the left-hand `dcmd` is complete, its processed output is used as input for the next `dcmd` in the pipeline. If any `dcmd` does not return a successful exit status, the pipeline is aborted.

An *expression* is a sequence of words that is evaluated to compute a 64-bit unsigned integer value. The words are evaluated using the rules described under `Arithmetic Expansion` below.

Commands

A *command* is one of the following:

pipeline [`!` *word* . . .] [`;`]

A simple-command or pipeline can be optionally suffixed with the `!` character, indicating that the debugger should open a `pipe(2)` and send the standard output of the last `dcmd` in the `mdb` pipeline to an external process created by executing `$SHELL -c` followed by the string formed by concatenating the words after the `!` character. For more details, refer to `Shell Escapes` below.

expression pipeline [`!` *word* . . .] [`;`]

A simple-command or pipeline can be prefixed with an expression. Before execution of the pipeline, the value of `dot` (the variable denoted by `."`) is set to the value of the expression.

expression , expression pipeline [`!` *word* . . .] [`;`]

A simple-command or pipeline can be prefixed with two expressions. The first is evaluated to determine the new value of `dot`, and the second is evaluated to determine a repeat count for the first `dcmd` in the pipeline. This `dcmd` will be executed *count* times before the next `dcmd` in the pipeline is executed. The repeat count only applies to the first `dcmd` in the pipeline.

, expression pipeline [`!` *word* . . .] [`;`]

If the initial expression is omitted, `dot` is not modified but the first `dcmd` in the pipeline will be repeated according to the value of the expression.

expression [`!` *word* . . .] [`;`]

A command can consist only of an arithmetic expression. The expression is evaluated and the `dot` variable is set to its value, and then the previous `dcmd` and arguments are executed using the new value of `dot`.

expression, *expression* [*!* *word* . . .] [;]

A command can consist only of a dot expression and repeat count expression. After dot is set to the value of the first expression, the previous dcmd and arguments are repeatedly executed the number of times specified by the value of the second expression.

, *expression* [*!* *word* . . .] [;]

If the initial expression is omitted, dot is not modified but the previous dcmd and arguments are repeatedly executed the number of times specified by the value of the count expression.

! *word* . . . [;]

If the command begins with the ! character, no dcmds are executed and the debugger simply executes \$SHELL -c followed by the string formed by concatenating the words after the ! character.

Comments A word beginning with // causes that word and all the subsequent characters up to a NEWLINE to be ignored.

Arithmetic Expansion Arithmetic expansion is performed when an mdb command is preceded by an optional expression representing a start address, or a start address and a repeat count. Arithmetic expansion can also be performed to compute a numerical argument for a dcmd. An arithmetic expression can appear in an argument list enclosed in square brackets preceded by a dollar sign (\$ [*expression*]), and will be replaced by the value of the expression.

Expressions may contain any of the following special words:

<i>integer</i>	The specified integer value. Integer values may be prefixed with 0i or 0I to indicate binary values, 0o or 0O to indicate octal values, 0t or 0T to indicate decimal values, and 0x or 0X to indicate hexadecimal values (the default).
0[tT][0-9]+.[0-9]+	The specified decimal floating point value, converted to its IEEE double-precision floating point representation.
'ccccccc'	The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters may be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte.
< <i>identifier</i>	The value of the variable named by <i>identifier</i> .
<i>identifier</i>	The value of the symbol named by <i>identifier</i> .
(<i>expression</i>)	The value of <i>expression</i> .
.	The value of dot.
&	The most recent value of dot used to execute a dcmd.

mdb(1)

+	The value of dot incremented by the current increment.
^	The value of dot decremented by the current increment.

The increment is a global variable that stores the total bytes read by the last formatting dcmd. For more information on the increment, refer to the discussion of `Formatting dcmds` below.

Unary operators are right associative and have higher precedence than binary operators. The unary operators are:

<i>#expression</i>	Logical negation.
<i>~expression</i>	Bitwise complement.
<i>-expression</i>	Integer negation.
<i>%expression</i>	The value of a pointer-sized quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.
<i>%/[csil]/expression</i>	The value of a char, short, int, or long-sized quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.
<i>%/[1248]/expression</i>	The value of a one, two, four, or eight-byte quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.
<i>*expression</i>	The value of a pointer-sized quantity at virtual address <i>expression</i> in the target's virtual address space.
<i>*/[csil]/expression</i>	The value of a char, short, int, or long-sized quantity at virtual address <i>expression</i> in the target's virtual address space.
<i>*/[1248]/expression</i>	The value of a one, two, four, or eight-byte quantity at virtual address <i>expression</i> in the target's virtual address space.

Binary operators are left associative and have lower precedence than unary operators. The binary operators, in order of precedence from highest to lowest, are:

*	Integer multiplication.
%	Integer division.
#	Left-hand side rounded up to next multiple of right-hand side.
+	Integer addition.
-	Integer subtraction.
<<	Bitwise shift left.

```

>>      Bitwise shift right.
==      Logical equality.
!=      Logical inequality.
&       Bitwise AND.
^       Bitwise exclusive OR.
|       Bitwise inclusive OR.

```

Quoting Each metacharacter described above (see `Syntax`) terminates a word unless quoted. Characters can be quoted (forcing `mdb` to interpret each character as itself without any special significance) by enclosing them in a pair of single (') or double (") quote marks. A single quote cannot appear within single quotes. Inside double quotes, `mdb` recognizes the C programming language character escape sequences.

Shell Escapes The `!` character can be used to create a pipeline between an `mdb` command and the user's shell. If the `$SHELL` environment variable is set, `mdb` will fork and exec this program for shell escapes; otherwise `/bin/sh` is used. The shell is invoked with the `-c` option followed by a string formed by concatenating the words after the `!` character. The `!` character takes precedence over all other metacharacters, except semicolon (`;`) and `NEWLINE`. Once a shell escape is detected, the remaining characters up to the next semicolon or `NEWLINE` are passed as is to the shell. The output of shell commands may not be piped to `mdb` `dcmds`. Commands executed by a shell escape have their output sent directly to the terminal, not to `mdb`.

Variables A *variable* is a variable name, a corresponding integer value, and a set of attributes. A variable name is a sequence of letters, digits, underscores, or periods. A variable can be assigned a value using the `> dcmd` or `: : typeset dcmd`, and its attributes can be manipulated using the `: : typeset dcmd`. Each variable's value is represented as a 64-bit unsigned integer. A variable may have one or more of the following attributes: read-only (cannot be modified by the user), persistent (cannot be unset by the user), and tagged (user-defined indicator).

The following variables are defined as persistent:

```

0          The most recent value printed using the /, \, ?, or = dcmd.
9          The most recent count used with the $< dcmd.
b          The virtual address of the base of the data section.
d          The size of the data section in bytes.
e          The virtual address of the entry point.
m          The initial bytes (magic number) of the target's primary object file,
           or zero if no object file has been read yet.
t          The size of the text section in bytes.

```

mdb(1)

hits	The count of the number of times the matched software event specifier has been matched. See <code>Event Callbacks</code> , below.
thread	The thread identifier of the current representative thread. The value of the identifier depends on the threading model used by the current target. See <code>Thread Support</code> , below.

In addition, the `mdb` kernel and process targets will export the current values of the representative thread's register set as named variables. The names of these variables will depend on the target's platform and instruction set architecture.

Symbol Name Resolution

As explained in the `Syntax` description above, a symbol identifier present in an expression context evaluates to the value of this symbol. The value typically denotes the virtual address of the storage associated with the symbol in the target's virtual address space. A target may support multiple symbol tables including, but not limited to, a primary executable symbol table, a primary dynamic symbol table, a run-time link-editor symbol table, and standard and dynamic symbol tables for each of a number of load objects (such as shared libraries in a user process, or kernel modules in the Solaris kernel). The target typically searches the primary executable's symbol tables first, and then one or more of the other symbol tables. Notice that ELF symbol tables only contain entries for external, global, and static symbols; automatic symbols do not appear in the symbol tables processed by `mdb`.

Additionally, `mdb` provides a private user-defined symbol table that is searched prior to any of the target symbol tables. The private symbol table is initially empty, and can be manipulated using the `:nmadd` and `:nmde1` dcmts. The `:nm -P` option can be used to display the contents of the private symbol table. The private symbol table allows the user to create symbol definitions for program functions or data that were either missing from the original program or stripped out. These definitions are then used whenever `mdb` converts a symbolic name to an address, or an address to the nearest symbol.

As targets contain multiple symbol tables, and each symbol table may include symbols from multiple object files, different symbols with the same name may exist. `mdb` uses the backquote (```) character as a symbol name scoping operator to allow the programmer to obtain the value of the desired symbol in this situation. The programmer can specify the scope used to resolve a symbol name as either: *object`name*, or *file`name*, or *object`file`name*. The object identifier refers to the name of a load object. The file identifier refers to the basename of a source file that has a symbol of type `STT_FILE` in the specified object's symbol table. The object identifier's interpretation depends on the target type.

The `mdb` kernel target expects *object* to specify the basename of a loaded kernel module. For example, the symbol name

```
specfs`_init
```

evaluates to the value of the `_init` symbol in the `specfs` kernel module.

The mdb process target expects *object* to specify the name of the executable or of a loaded shared library. It may take any of the following forms:

1. An exact match (that is, a full pathname): `/usr/lib/libc.so.1`
2. An exact basename match: `libc.so.1`
3. An initial basename match up to a `''` suffix: `libc.so` or `libc`
4. The literal string `a.out` is accepted as an alias for the executable.

The process target will also accept any of the four forms described above preceded by an optional link-map id (lmid). The lmid prefix is specified by an initial "LM" followed by the link-map id in hexadecimal followed by an additional backquote. For example, the symbol name

```
LM0`libc.so.1`_init
```

will evaluate to the value of the `_init` symbol in the `libc.so.1` library that is loaded on link-map 0 (LM_ID_BASE). The link-map specifier may be necessary to resolve symbol naming conflicts in the event that the same library is loaded on more than one link map. For more information on link maps, refer to the *Linker and Libraries Guide* and `dlopen(3DL)`. Link-map identifiers will be displayed when symbols are printed according to the setting of the `showlmid` option, as described under OPTIONS, below.

In the case of a naming conflict between symbols and hexadecimal integer values, mdb will attempt to evaluate an ambiguous token as a symbol first, before evaluating it as an integer value. For example, the token `f` may either refer to the decimal integer value 15 specified in hexadecimal (the default base), or to a global variable named `f` in the target's symbol table. If a symbol with an ambiguous name is present, the integer value can be specified by using an explicit `0x` or `0X` prefix.

dcmd and Walker Name Resolution

As described earlier, each mdb dmod provides a set of dcmds and walkers. dcmds and walkers are tracked in two distinct, global namespaces. mdb also keeps track of a dcmd and walker namespace associated with each dmod. Identically named dcmds or walkers within a given dmod are not allowed: a dmod with this type of naming conflict will fail to load. Name conflicts between dcmds or walkers from different dmods are allowed in the global namespace. In the case of a conflict, the first dcmd or walker with that particular name to be loaded is given precedence in the global namespace. Alternate definitions are kept in a list in load order. The backquote character (```) may be used in a dcmd or walker name as a scoping operator to select an alternate definition. For example, if dmods `m1` and `m2` each provide a dcmd `d`, and `m1` is loaded prior to `m2`, then:

```

: : d           Executes m1's definition of d.
: : m1 `d       Executes m1's definition of d.
: : m2 `d       Executes m2's definition of d.
```

mdb(1)

If module `m1` were now unloaded, the next `dcmd` on the global definition list (`m2 `d`) would be promoted to global visibility. The current definition of a `dcmd` or walker can be determined using the `::which dcmd`, described below. The global definition list can be displayed using the `::which -v` option.

dcmd Pipelines

`dcmds` can be composed into a pipeline using the `|` operator. The purpose of a pipeline is to pass a list of values, typically virtual addresses, from one `dcmd` or walker to another. Pipeline stages might be used to map a pointer from one type of data structure to a pointer to a corresponding data structure, to sort a list of addresses, or to select the addresses of structures with certain properties.

`mdb` executes each `dcmd` in the pipeline in order from left to right. The leftmost `dcmd` is executed using the current value of `dot`, or using the value specified by an explicit expression at the start of the command. When a `|` operator is encountered, `mdb` creates a pipe (a shared buffer) between the output of the `dcmd` to its left and the `mdb` parser, and an empty list of values. As the `dcmd` executes, its standard output is placed in the pipe and then consumed and evaluated by the parser, as if `mdb` were reading this data from standard input. Each line must consist of an arithmetic expression terminated by a `NEWLINE` or semicolon (`;`). The value of the expression is appended to the list of values associated with the pipe. If a syntax error is detected, the pipeline is aborted.

When the `dcmd` to the left of a `|` operator completes, the list of values associated with the pipe is then used to invoke the `dcmd` to the right of the `|` operator. For each value in the list, `dot` is set to this value and the right-hand `dcmd` is executed. Only the rightmost `dcmd` in the pipeline has its output printed to standard output. If any `dcmd` in the pipeline produces output to standard error, these messages are printed directly to standard error and are not processed as part of the pipeline.

Signal Handling

The debugger ignores the `PIPE` and `QUIT` signals. The `INT` signal aborts the command that is currently executing. The debugger intercepts and provides special handling for the `ILL`, `TRAP`, `EMT`, `FPE`, `BUS`, and `SEGV` signals. If any of these signals are generated asynchronously (that is, delivered from another process using `kill(2)`), `mdb` will restore the signal to its default disposition and dump core. However, if any of these signals are generated synchronously by the debugger process itself and a `dcmd` from an externally loaded `dmod` is currently executing, and standard input is a terminal, `mdb` will provide a menu of choices allowing the user to force a core dump, quit without producing a core dump, stop for attach by a debugger, or attempt to resume. The resume option will abort all active commands and unload the `dmod` whose `dcmd` was active at the time the fault occurred. It can then be subsequently re-loaded by the user. The resume option provides limited protection against buggy `dcmds`. Refer to `WARNINGS, Use of the Error Recovery Mechanism`, below for information about the risks associated with the resume option.

Command Re-entry

The text of the last `HISTSIZE` (default 128) commands entered from a terminal device are saved in memory. The in-line editing facility, described next, provides key mappings for searching and fetching elements from the history list.

In-line Editing

If standard input is a terminal device, `mdb` provides some simple emacs-style facilities for editing the command line. The `search`, `previous`, and `next` commands in edit mode provide access to the history list. Only strings, not patterns, are matched when searching. In the table below, the notation for control characters is caret (^) followed by a character shown in upper case. The notation for escape sequences is M- followed by a character. For example, M-f (pronounced meta-eff) is entered by depressing ESC followed by 'f', or by depressing Meta followed by 'f' on keyboards that support a Meta key. A command line is committed and executed using RETURN or NEWLINE. The edit commands are:

^F	Move cursor forward (right) one character.
M-f	Move cursor forward one word.
^B	Move cursor backward (left) one character.
M-b	Move cursor backward one word.
^A	Move cursor to start of line.
^E	Move cursor to end of line.
^D	Delete current character, if the current line is not empty. If the current line is empty, ^D denotes EOF and the debugger will exit.
M-^H	(Meta-backspace) Delete previous word.
^K	Delete from the cursor to the end of the line.
^L	Clear the screen and reprint the current line.
^T	Transpose current character with next character.
^N	Fetch the next command from the history. Each time ^N is entered, the next command forward in time is retrieved.
^P	Fetch the previous command from the history. Each time ^P is entered, the next command backward in time is retrieved.
^R[<i>string</i>]	Search backward in the history for a previous command line containing <i>string</i> . The string should be terminated by a RETURN or NEWLINE. If <i>string</i> is omitted, the previous history element containing the most recent string is retrieved.

The editing mode also interprets the following user-defined sequences as editing commands. User defined sequences can be read or modified using the `stty(1)` command.

erase	User defined erase character (usually ^H or ^?). Delete previous character.
intr	User defined interrupt character (usually ^C). Abort the current command and print a new prompt.

mdb(1)

kill	User defined kill character (usually ^U). Kill the entire current command line.
quit	User defined quit character (usually ^\). Quit the debugger.
suspend	User defined suspend character (usually ^Z). Suspend the debugger.
werase	User defined word erase character (usually ^W). Erase the preceding word.

On keyboards that support an extended keypad with arrow keys, mdb will interpret these keystrokes as editing commands:

up-arrow	Fetch the previous command from the history (same as ^P).
down-arrow	Fetch the next command from the history (same as ^N).
left-arrow	Move cursor backward one character (same as ^B).
right-arrow	Move cursor forward one character (same as ^F).

Output Pager

mdb provides a built-in output pager. The output pager is enabled if the debugger's standard output is a terminal device. Each time a command is executed, mdb will pause after one screenful of output is produced and will display a pager prompt:

```
>> More [<space>, <cr>, q, n, c, a] ?
```

The following key sequences are recognized by the pager:

SPACE	Display the next screenful of output.
a, A	Abort the current top-level command and return to the prompt.
c, C	Continue displaying output without pausing at each screenful until the current top-level command is complete.
n, N, NEWLINE, RETURN	Display the next line of output.
q, Q, ^C, ^\	Quit (abort) the current dcmd only.

Formatting dcmds

The /, \, ?, and = metacharacters are used to denote the special output formatting dcmds. Each of these dcmds accepts an argument list consisting of one or more format characters, repeat counts, or quoted strings. A format character is one of the ASCII characters shown in the table below. Format characters are used to read and format data from the target. A repeat count is a positive integer preceding the format character that is always interpreted in base 10 (decimal). A repeat count may also be specified as an expression enclosed in square brackets preceded by a dollar sign (\$ []). A string argument must be enclosed in double-quotes (" "). No blanks are necessary between format arguments.

The formatting dcmds are:

/	Display data from the target's virtual address space starting at the virtual address specified by dot.
\	Display data from the target's physical address space starting at the physical address specified by dot.
?	Display data from the target's primary object file starting at the object file location corresponding to the virtual address specified by dot.
=	Display the value of dot itself in each of the specified data formats. The = dcmd is therefore useful for converting between bases and performing arithmetic.

In addition to dot, mdb keeps track of another global value called the *increment*. The increment represents the distance between dot and the address following all the data read by the last formatting dcmd. For example, if a formatting dcmd is executed with dot equal to address A, and displays a 4-byte integer, then after this dcmd completes, dot is still A, but the increment is set to 4. The + character (described under *Arithmetic Expansion* above) would now evaluate to the value A + 4, and could be used to reset dot to the address of the next data object for a subsequent dcmd.

Most format characters increase the value of the increment by the number of bytes corresponding to the size of the data format, shown in the table. The table of format characters can be displayed from within mdb using the `::formats` dcmd. The format characters are:

+	increment dot by the count (variable size)
-	decrement dot by the count (variable size)
B	hexadecimal int (1 byte)
C	character using C character notation (1 byte)
D	decimal signed int (4 bytes)
E	decimal unsigned long long (8 bytes)
F	double (8 bytes)
G	octal unsigned long long (8 bytes)
H	swap bytes and shorts (4 bytes)
I	address and disassembled instruction (variable size)
J	hexadecimal long long (8 bytes)
K	hexadecimal uintptr_t (4 or 8 bytes)
N	newline
O	octal unsigned int (4 bytes)

mdb(1)

P	symbol (4 or 8 bytes)
Q	octal signed int (4 bytes)
R	binary int (8 bytes)
S	string using C string notation (variable size)
T	horizontal tab
U	decimal unsigned int (4 bytes)
V	decimal unsigned int (1 byte)
W	default radix unsigned int (4 bytes)
X	hexadecimal int (4 bytes)
Y	decoded time32_t (4 bytes)
Z	hexadecimal long long (8 bytes)
^	decrement dot by increment * count (variable size)
a	dot as symbol+offset
b	octal unsigned int (1 byte)
c	character (1 byte)
d	decimal signed short (2 bytes)
e	decimal signed long long (8 bytes)
f	float (4 bytes)
g	octal signed long long (8 bytes)
h	swap bytes (2 bytes)
i	disassembled instruction (variable size)
n	newline
o	octal unsigned short (2 bytes)
p	symbol (4 or 8 bytes)
q	octal signed short (2 bytes)
r	whitespace
s	raw string (variable size)
t	horizontal tab
u	decimal unsigned short (2 bytes)
v	decimal signed int (1 byte)

w	default radix unsigned short (2 bytes)
x	hexadecimal short (2 bytes)
y	decoded time64_t (8 bytes)

The /, \, and ? formatting dcmts can also be used to write to the target's virtual address space, physical address space, or object file by specifying one of the following modifiers as the first format character, and then specifying a list of words that are either immediate values or expressions enclosed in square brackets preceded by a dollar sign (\$ []).

The write modifiers are:

v	Write the lowest byte of the value of each expression to the target beginning at the location specified by dot.
w	Write the lowest two bytes of the value of each expression to the target beginning at the location specified by dot.
W	Write the lowest 4 bytes of the value of each expression to the target beginning at the location specified by dot.
Z	Write the complete 8 bytes of the value of each expression to the target beginning at the location specified by dot.

The /, \, and ? formatting dcmts can also be used to search for a particular integer value in the target's virtual address space, physical address space, and object file, respectively, by specifying one of the following modifiers as the first format character, and then specifying a value and optional mask. The value and mask are each specified as either immediate values or expressions enclosed in square brackets preceded by a dollar sign. If only a value is specified, mdb reads integers of the appropriate size and stops at the address containing the matching value. If a value V and mask M are specified, mdb reads integers of the appropriate size and stops at the address containing a value X where $(X \& M) == V$. At the completion of the dcmtd, dot is updated to the address containing the match. If no match is found, dot is left at the last address that was read.

The search modifiers are:

l	Search for the specified 2-byte value.
L	Search for the specified 4-byte value.
M	Search for the specified 8-byte value.

mdb(1)

Notice that for both user and kernel targets, an address space is typically composed of a set of discontinuous segments. It is not legal to read from an address that does not have a corresponding segment. If a search reaches a segment boundary without finding a match, it will abort when the read past the end of the segment boundary fails.

Execution Control

mdb provides facilities for controlling and tracing the execution of a live running program. Currently, only the user process target provides support for execution control. mdb provides a simple model of execution control: a target process can be started from within the debugger using `::run`, or mdb can attach to an existing process using `::A`, `::attach`, or the `-p` command-line option, as described below. A list of traced software events can be specified by the user. Each time a traced event occurs in the target process, all threads in the target stop, the thread that triggered the event is chosen as the representative thread, and control returns to the debugger. Once the target program is set running, control can be asynchronously returned to the debugger by typing the user-defined interrupt character (typically `^C`).

A *software event* is a state transition in the target program that is observed by the debugger. For example, the debugger may observe the transition of a program counter register to a value of interest (a breakpoint) or the delivery of a particular signal.

A *software event specifier* is a description of a class of software events that is used by the debugger to instrument the target program in order to observe these events. The `::events` dcmd is used to list the software event specifiers. A set of standard properties is associated with each event specifier, as described under `::events`, below.

The debugger can observe a variety of different software events, including breakpoints, watchpoints, signals, machine faults, and system calls. New specifiers can be created using `::bp`, `::fltbp`, `::sigbp`, `::sysbp`, or `::wp`. Each specifier has an associated callback (an mdb command string to execute as if it had been typed at the command prompt) and a set of properties, as described below. Any number of specifiers for the same event may be created, each with different callbacks and properties. The current list of traced events and the properties of the corresponding event specifiers can be displayed using the `::events` dcmd. The event specifier properties are defined as part of the description of the `::events` and `::evset` dcmds, below.

The execution control built-in dcmds, described below, are always available, but will issue an error message indicating they are not supported if applied to a target that does not support execution control. For more information about the interaction of `exec`, `attach`, `release`, and `job` control with debugger execution control, refer to NOTES, below.

Event Callbacks

The `::evset` dcmd and event tracing dcmds allow you to associate an event callback (using the `-c` option) with each event specifier. The event callbacks are strings that represent mdb commands to execute when the corresponding event occurs in the target. These commands are executed as if they had been typed at the command

prompt. Before executing each callback, the dot variable is set to the value of the representative thread's program counter and the "hits" variable is set to the number of times this specifier has been matched, including the current match.

If the event callbacks themselves contain one or more commands to continue the target (for example, `::cont` or `::step`), these commands do not immediately continue the target and wait for it to stop again. Instead, inside of an event callback, the continue dcmds note that a continue operation is now pending, and then return immediately. Therefore, if multiple dcmds are included in an event callback, the step or continue dcmd should be the last command specified. Following the execution of *all* event callbacks, the target will immediately resume execution if *all* matching event callbacks requested a continue. If conflicting continue operations are requested, the operation with the highest precedence determines what type of continue will occur. The order of precedence from highest to lowest is: step, step-over (next), step-out, continue.

Thread Support

`mdb` provides facilities to examine the stacks and registers of each thread associated with the target. The persistent "thread" variable contains the current representative thread identifier. The format of the thread identifier depends on the target. The `::regs` and `::fpregs` dcmds can be used to examine the register set of the representative thread, or of another thread if its register set is currently available. In addition, the register set of the representative thread is exported as a set of named variables. The user can modify the value of one or more registers by applying the `>` dcmd to the corresponding named variable.

The `mdb` kernel target exports the virtual address of the corresponding internal thread structure as the identifier for a given thread. The *Solaris Modular Debugger Guide* provides more information on debugging support for threads in the Solaris kernel. The `mdb` process target provides proper support for examination of multi-threaded user processes that use the native `lwp_*` interfaces, `/usr/lib/libthread.so` or `/usr/lib/lwp/libthread.so`. When debugging a live user process, `mdb` will detect if a single threaded process `dlopens` or closes `libthread` and will automatically adjust its view of the threading model on-the-fly. The process target thread identifiers will correspond to either the `lwpid_t`, `thread_t`, or `pthread_t` of the representative, depending on the threading model used by the application.

If `mdb` is debugging a user process target and the target makes use of compiler-supported thread-local storage, `mdb` will automatically evaluate symbol names referring to thread-local storage to the address of the storage corresponding to the current representative thread. The `::tls` built-in dcmd can be used to display the value of the symbol for threads other than the representative thread.

Built-in dcmds

`mdb` provides a set of built-in dcmds that are always defined. Some of these dcmds are only applicable to certain targets: if a dcmd is not applicable to the current target, it will fail and print a message indicating "command is not supported by current target". In many cases, `mdb` provides a mnemonic equivalent (`::identifier`) for the legacy `adb(1)` dcmd names. For example, `::quit` is provided as the equivalent of `$q`. Programmers who are experienced with `adb(1)` or who appreciate brevity or arcana may prefer the `$` or `:` forms of the built-ins. Programmers who are new to `mdb` may

mdb(1)

prefer the more verbose `::` form. The built-ins are shown in alphabetical order. If a `$` or `:` form has a `::identifier` equivalent, it is shown underneath the `::identifier` form. The built-in dcmds are:

`> variable-name`

`>/modifier/variable-name`

Assign the value of dot to the specified named variable. Some variables are read-only and may not be modified. If the `>` is followed by a modifier character surrounded by `/ /`, then the value is modified as part of the assignment. The modifier characters are:

<code>c</code>	unsigned char quantity (1-byte)
<code>s</code>	unsigned short quantity (2-byte)
<code>i</code>	unsigned int quantity (4-byte)
<code>l</code>	unsigned long quantity (4-byte in 32-bit, 8-byte in 64-bit)

Notice that these operators do not perform a cast. Instead, they fetch the specified number of low-order bytes (on little-endian architectures) or high-order bytes (big-endian architectures). Modifiers are provided for backwards compatibility; the `mdb */modifier/` and `*/modifier/` syntax should be used instead.

`$< macro-name`

Read and execute commands from the specified macro file. The filename may be given as an absolute or relative path. If the filename is a simple name (that is, if it does not contain a `'/'`), `mdb` will search for it in the macro file include path. If another macro file is currently being processed, this file is closed and replaced with the new file.

`$<< macro-name`

Read and execute commands from the specified macro file (as with `$<`), but do not close the current open macro file.

`$?`

Print the process-ID and current signal of the target if it is a user process or core file, and then print the general register set of the representative thread.

`[address] $C [count]`

Print a C stack backtrace, including stack frame pointer information. If the dcmd is preceded by an explicit *address*, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than *count* arguments are displayed for each stack frame in the output.

`[base] $d`

Get or set the default output radix. If the dcmd is preceded by an explicit expression, the default output radix is set to the given *base*; otherwise the current radix is printed in base 10 (decimal). The default radix is base 16 (hexadecimal).

`$e`

Print a list of all known external (global) symbols of type object or function, the value of the symbol, and the first 4 (32-bit mdb) or 8 (64-bit mdb) bytes stored at this location in the target's virtual address space. The `::nm` dcmd provides more flexible options for displaying symbol tables.

`$P` *prompt-string*

Set the prompt to the specified *prompt-string*. The default prompt is `'>'`. The prompt can also be set using `::set -P` or the `-P` command-line option.

distance `$s`

Get or set the symbol matching *distance* for address-to-symbol-name conversions. The symbol matching distance modes are discussed along with the `-s` command-line option under OPTIONS, below. The symbol matching distance may also be modified using the `::set -s` option. If no distance is specified, the current setting is displayed.

`$v`

Print a list of the named variables that have non-zero values. The `::vars` dcmd provides other options for listing variables.

width `$w`

Set the output page *width* to the specified value. Typically, this command is not necessary as mdb queries the terminal for its width and handles resize events.

`$W`

Re-open the target for writing, as if mdb had been executed with the `-w` option on the command line. Write mode can also be enabled with the `::set -w` option.

`[pid] ::attach [core | pid]`

`[pid] :A [core | pid]`

If the user process target is active, attach to and debug the specified process-ID or *core* file. The core file pathname should be specified as a string argument. The process-ID may be specified as the string argument, or as the value of the expression preceding the dcmd. Recall that the default base is hexadecimal, so decimal PIDs obtained using `pgrep(1)` or `ps(1)` should be preceded with `"0t"` when specified as expressions.

`[address] : :bp [+/-dDesT] [-c cmd] [-n count] sym ...`

`address :b [cmd ...]`

Set a breakpoint at the specified locations. The `::bp` dcmd sets a breakpoint at each address or symbol specified, including an optional address specified by an explicit expression preceding the dcmd, and each string or immediate value following the dcmd. The arguments may either be symbol names or immediate values denoting a particular virtual address of interest. If a symbol name is specified, it may refer to a symbol that cannot yet be evaluated in the target process. That is, it may consist of an object name and function name in a load object that has not yet been opened. In this case, the breakpoint is deferred and it will not be active in the target until an object matching the given name is loaded. The breakpoint will be automatically enabled when the load object is opened. Breakpoints on symbols defined in a shared library should always be set using a symbol name and not using an address

mdb(1)

expression, as the address may refer to the corresponding Procedure Linkage Table (PLT) entry instead of the actual symbol definition. Breakpoints set on PLT entries may be overwritten by the run-time link-editor when the PLT entry is subsequently resolved to the actual symbol definition. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset` dcmd, as described below. If the `:b` form of the dcmd is used, a breakpoint is only set at the virtual address specified by the expression preceding the dcmd. The arguments following the `:b` dcmd are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

`::cat filename ...`

Concatenate and display files. Each filename may be specified as a relative or absolute pathname. The file contents will be printed to standard output, but will not be passed to the output pager. This dcmd is intended to be used with the `|` operator; the programmer can initiate a pipeline using a list of addresses stored in an external file.

`::cont [SIG]`

`:c [SIG]`

Suspend the debugger, continue the target program, and wait for it to terminate or stop following a software event of interest. If the target is already running because the debugger was attached to a running program with the `-o nostop` option enabled, this dcmd simply waits for the target to terminate or stop after an event of interest. If an optional signal name or number (see `signal(3HEAD)`) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If the `SIGINT` signal is traced, control may be asynchronously returned to the debugger by typing the user-defined interrupt character (usually `^C`). This `SIGINT` signal will be automatically cleared and will not be observed by the target the next time it is continued. If no target program is currently running, `::cont` will start a new program running as if by `::run`.

`address ::context`

`address $p`

Context switch to the specified process. A context switch operation is only valid when using the kernel target. The process context is specified using the `address` of its `proc` structure in the kernel's virtual address space. The special context address "0" is used to denote the context of the kernel itself. `mdb` can only perform a context switch when examining a crash dump if the dump contains the physical memory pages of the specified user process (as opposed to just kernel pages). The kernel crash dump facility can be configured to dump all pages or the pages of the current user process using `dumpadm(1M)`. The `::status` dcmd can be used to display the contents of the current crash dump.

When the user requests a context switch from the kernel target, `mdb` constructs a new target representing the specified user process. Once the switch occurs, the new target interposes its dcmds at the global level: thus the `/` dcmd will now format and display data from the virtual address space of the user process, the `::mappings` dcmd will display the mappings in the address space of the user process, and so on. The kernel target can be restored by executing `0 ::context`.

```

::dcmds
    List the available dcmds and print a brief description for each one.

[ address ] ::delete [ id | all ]
[ address ] :d [ id | all ]
    Delete the event specifiers with the given id number. The id number argument is interpreted in decimal by default. If an optional address is specified preceding the dcmd, all event specifiers that are associated with the given virtual address are deleted (for example, all breakpoints or watchpoints affecting that address). If the special argument "all" is given, all event specifiers are deleted, except those that are marked sticky (T flag). The ::events dcmd displays the current list of event specifiers.

[ address ] ::dis [ -fw ] [ -n count ] [ address ]
    Disassemble starting at or around the address specified by the final argument, or the current value of dot. If the address matches the start of a known function, the entire function is disassembled. Otherwise, a "window" of instructions before and after the specified address is printed in order to provide context. By default, instructions are read from the target's virtual address space. If the -f option is present, instructions are read from the target's object file instead. The -f option is enabled by default if the debugger is not currently attached to a live process, core file, or crash dump. The -w option can be used to force "window"-mode, even if the address is the start of a known function. The size of the window defaults to ten instructions; the number of instructions can be specified explicitly using the -n option.

::disasms
    List the available disassembler modes. When a target is initialized, mdb will attempt to select the appropriate disassembler mode. The user can change the mode to any of the modes listed using the ::dismode dcmd.

::dismode [ mode ]
$V [ mode ]
    Get or set the disassembler mode. If no argument is specified, print the current disassembler mode. If a mode argument is specified, switch the disassembler to the specified mode. The list of available disassemblers can be displayed using the ::disasms dcmd.

::dmods [ -l ] [ module-name ]
    List the loaded debugger modules. If the -l option is specified, the list of the dcmds and walkers associated with each dmod is printed below its name. The output can be restricted to a particular dmod by specifying its name as an additional argument.

[ address ] ::dump [ -eqrstu ] [ -f | -p ]
[ -g bytes ] [ -w paragraphs ]
    Print a hexadecimal and ASCII memory dump of the 16-byte aligned region of memory containing the address specified by dot. If a repeat count is specified for ::dump, this is interpreted as a number of bytes to dump rather than a number of iterations. The ::dump dcmd also recognizes the following options:

```

mdb(1)

`-e` Adjusts for endian-ness. The `-e` option assumes 4-byte words. The `-g` option can be used to change the default word size.

`-f` Reads data from the object file location corresponding to the given virtual address instead of from the target's virtual address space. The `-f` option is enabled by default if the debugger is not currently attached to a live process, core file, or crash dump.

`-g bytes` Displays bytes in groups of *bytes*. The default group size is 4 bytes. The group size must be a power of two that divides the line width.

`-p` Interprets *address* as a physical address location in the target's address space instead of a virtual address.

`-q` Does not print an ASCII decoding of the data.

`-r` Numbers lines relative to the start address instead of with the explicit address of each line. This option implies the `-u` option.

`-s` Elides repeated lines.

`-t` Only reads from and displays the contents of the specified addresses, instead of reading and printing entire lines.

`-u` Unaligns output instead of aligning the output at a paragraph boundary.

`-w paragraphs` Displays paragraphs at 16-byte paragraphs per line. The default number of *paragraphs* is one. The maximum value accepted for `-w` is 16.

`::echo [string | value ...]`
Print the arguments separated by blanks and terminated by a NEWLINE to standard output. Expressions enclosed in `$ []` will be evaluated to a value and printed in the default base.

`::eval command`
Evaluate and execute the specified string as a command. If the command contains metacharacters or whitespace, it should be enclosed in double or single quotes.

`::events [-av]`
`$b [-av]`
Display the list of software event specifiers. Each event specifier is assigned a unique ID number that can be used to delete or modify it at a later time. The debugger may also have its own internal events enabled for tracing. These events will only be displayed if the `-a` option is present. If the `-v` option is present, a more verbose display, including the reason for any specifier inactivity, will be shown. Here is some sample output:

```
> ::events
  ID S TA HT LM Description Action
-----
```

```

[ 1 ] - T 1 0 stop on SIGINT          -
[ 2 ] - T 0 0 stop on SIGQUIT        -
[ 3 ] - T 0 0 stop on SIGILL         -
...
[ 11] - T 0 0 stop on SIGXCPU        -
[ 12] - T 0 0 stop on SIGXFSZ       -
[ 13] -  2 0 stop at libc`printf    ::echo printf
>

```

The following table explains the meaning of each column. A summary of this information is available using `::help events`.

ID	The event specifier identifier. The identifier will be shown in square brackets [] if the specifier is enabled, in parentheses () if the specifier is disabled, or in angle brackets < > if the target program is currently stopped on an event that matches the given specifier.
S	The event specifier state. The state will be one of the following symbols: <ul style="list-style-type: none"> - The event specifier is idle. When no target program is running, all specifiers are idle. When the target program is running, a specifier may be idle if it cannot be evaluated (for example, a deferred breakpoint in a shared object that is not yet loaded). + The event specifier is active. When the target is continued, events of this type will be detected by the debugger. * The event specifier is armed. This state means that the target is currently running with instrumentation for this type of event. This state is only visible if the debugger is attached to a running program with the <code>-o nostop</code> option. ! The event specifier was not armed due to an operating system error. The <code>::events -v</code> option can be used to display more information about the reason the instrumentation failed.
TA	The Temporary, Sticky, and Automatic event specifier properties. One or more of the following symbols may be shown: <ul style="list-style-type: none"> t The event specifier is temporary, and will be deleted the next time the target stops, regardless of whether it is matched.

mdb(1)

	T	The event specifier is sticky, and will be not be deleted by <code>::delete all</code> or <code>:z</code> . The specifier can be deleted by explicitly specifying its id number to <code>::delete</code> .
	d	The event specifier will be automatically disabled when the hit count is equal to the hit limit.
	D	The event specifier will be automatically deleted when the hit count is equal to the hit limit.
	s	The target will automatically stop when the hit count is equal to the hit limit.
HT		The current hit count. This column displays the number of times the corresponding software event has occurred in the target since the creation of this event specifier.
LM		The current hit limit. This column displays the limit on the hit count at which the auto-disable, auto-delete, or auto-stop behavior will take effect. These behaviors can be configured using the <code>::evset dcmd</code> , described below.
Description		A description of the type of software event that is matched by the given specifier.
Action		The callback string to execute when the corresponding software event occurs. This callback is executed as if it had been typed at the command prompt.

`[id] ::evset [+/-dDestT] [-c cmd] [-n count] id ...`

Modify the properties of one or more software event specifiers. The properties are set for each specifier identified by the optional expression preceding the `dcmd` and an optional list of arguments following the `dcmd`. The argument list is interpreted as a list of decimal integers, unless an explicit radix is specified. The `::evset dcmd` recognizes the following options:

- d Disables the event specifier when the hit count reaches the hit limit. If the `+d` form of the option is given, this behavior is disabled. Once an event specifier is disabled, the debugger will remove any corresponding instrumentation and will ignore the corresponding software events until the specifier is subsequently re-enabled. If the `-n` option is not present, the specifier is disabled immediately.
- D Deletes the event specifier when the hit count reaches the hit limit. If the `+D` form of the option is given, this behavior is disabled. The `-D` option takes precedence over the `-d` option. The hit limit can be configured using the `-n` option.
- e Enables the event specifier. If the `+e` form of the option is given, the specifier is disabled.

- s Stops the target program when the hit count reaches the hit limit. If the +s form of the option is given, this behavior is disabled. The -s behavior tells the debugger to act as if the ::cont were issued following each execution of the specifier's callback, except for the Nth execution, where N is the current value of the specifier's hit limit. The -s option takes precedence over both the -D option and the -d option.
- t Marks the event specifier as temporary. Temporary specifiers are automatically deleted the next time the target stops, regardless of whether it stopped as the result of a software event corresponding to the given specifier. If the +t form of the option is given, the temporary marker is removed. The -t option takes precedence over the -T option.
- T Marks the event specifier as sticky. Sticky specifiers will not be deleted by ::delete all or :z. They can be deleted by specifying the corresponding specifier ID as an explicit argument to ::delete. If the +T form of the option is given, the sticky property is removed. The default set of event specifiers are all initially marked sticky.
- c Executes the specified *cmd* string each time the corresponding software event occurs in the target program. The current callback string can be displayed using ::events.
- n Sets the current value of the hit limit to *count*. If no hit limit is currently set and the -n option does not accompany -s or D, the hit limit will be set to one.

A summary of this information is available using ::help evset.

::files

\$f

Print a list of the known source files (symbols of type STT_FILE present in the various target symbol tables).

[*flt*] ::fltbp [+/-dDestT] [-c *cmd*] [-n *count*] *flt* ...

Trace the specified machine faults. The faults are identified using an optional fault number preceding the dcmd, or a list of fault names or numbers (see <sys/fault.h>) following the dcmd. The -d, -D, -e, -s, -t, -T, -c, and -n options have the same meaning as they do for the ::evset dcmd.

[*thread*] ::fpregs

[*thread*] \$x, \$X, \$y, \$Y

Print the floating-point register set of the representative thread. If a thread is specified, the floating point registers of that thread are displayed. The thread expression should be one of the thread identifiers described under Thread Support, above.

::formats

List the available output format characters for use with the /, \, ?, and = formatting dcmds. The formats and their use is described under Formatting dcmds, above.

mdb(1)

```
::grep command
    Evaluate the specified command string, and then print the old value of dot if the
    new value of dot is non-zero. If the command contains whitespace or
    metacharacters, it must be quoted. The ::grep dcmd can be used in pipelines to
    filter a list of addresses.

::help [ dcmd-name ]
    With no arguments, the ::help dcmd prints a brief overview of the help facilities
    available in mdb. If a dcmd-name is specified, mdb will print a usage summary for
    that dcmd.

signal :i
    If the target is a live user process, ignore the specified signal and allow it to be
    delivered transparently to the target. All event specifiers that are tracing delivery of
    the specified signal will be deleted from the list of traced events. By default, the set
    of ignored signals is initialized to the complement of the set of signals that cause a
    process to dump core by default (see signal(3HEAD)), except for SIGINT, which
    is traced by default.

$!
    Display the list of signals that are ignored by the debugger and that will be handled
    directly by the target. More information on traced signals can be obtained using the
    ::events dcmd.

::kill
:k
    Forcibly terminate the target if it is a live user process. The target will also be
    forcibly terminated when the debugger exits if it was created by the debugger using
    ::run.

$L
    Print the LWPID of the representative thread, if the target is a user process.

$!
    Print the LWPIDs of each LWP in the target, if the target is a user process.

[ address ] ::list type member [ variable-name ]
    Walk through the elements of a linked list data structure and print the address of
    each element in the list. The address of the first element in the list can be specified
    using an optional address. Otherwise, the list is assumed to start at the current
    value of dot. The type parameter must name a C struct or union type and is used to
    describe the type of the list elements so that mdb can read in objects of the
    appropriate size. The member parameter is used to name the member of type that
    contains a pointer to the next list element. The ::list dcmd will continue iterating
    until a NULL pointer is encountered, the first element is reached again (a circular
    list), or an error occurs while reading an element. If the optional variable-name is
    specified, the specified variable will be assigned the value returned at each step of
    the walk when mdb invokes the next stage of a pipeline. The ::list dcmd may
    only be used with objects that contain symbolic debugging information designed
    for use with mdb. Refer to NOTES, Symbolic Debugging Information, below
    for more information.
```

```
::load [ -s ] module-name
```

Load the specified dmod. The module name may be given as an absolute or relative path. If *module-name* is a simple name (that is, does not contain a '/'), mdb will search for it in the module library path. Modules with conflicting names may not be loaded; the existing module must be unloaded first. If the *-s* option is present, mdb will remain silent and not issue any error messages if the module is not found or could not be loaded.

```
::log [ -d | [ -e ] filename ]
```

```
$> [ filename ]
```

Enable or disable the output log. mdb provides an interactive logging facility where both the input commands and standard output can be logged to a file while still interacting with the user. The *-e* option enables logging to the specified file, or re-enables logging to the previous log file if no filename is given. The *-d* option disables logging. If the *\$>* dcmd is used, logging is enabled if a filename argument is specified; otherwise, logging is disabled. If the specified log file already exists, mdb appends any new log output to the file.

```
::map command
```

Map the value of dot to a corresponding value using the *command* specified as a string argument, and then print the new value of dot. If the command contains whitespace or metacharacters, it must be quoted. The *::map* dcmd can be used in pipelines to transform the list of addresses into a new list of addresses.

```
[ address ] ::mappings [ name ]
```

```
[ address ] $m [ name ]
```

Print a list of each mapping in the target's virtual address space, including the address, size, and description of each mapping. If the dcmd is preceded by an *address*, mdb will only show the mapping that contains the given address. If a string *name* argument is given, mdb will only show the mapping matching that description.

```
::next [ SIG ]
```

```
:e [ SIG ]
```

Step the target program one instruction, but step over subroutine calls. If an optional signal name or number (see `signal(3HEAD)`) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If no target program is currently running, *::next* will start a new program running as if by *::run* and stop at the first instruction.

```
[ address ] ::nm [ -DPdghnopuvx ] [ -t types ]
```

```
[ -f format ] [ object ]
```

Print the symbol tables associated with the current target. If an optional address preceding the dcmd is specified, only the symbol table entry for the symbol corresponding to *address* is displayed. If an *object* is specified, only the symbol table for this load object is displayed. The *::nm* dcmd also recognizes the following options:

<i>-D</i>	Prints <code>.dynsym</code> (dynamic symbol table) instead of <code>.syntab</code> .
-----------	--

mdb(1)

-P	Prints the private symbol table instead of <code>.symtab</code> .
-d	Prints value and size fields in decimal.
-g	Prints only global symbols.
-h	Suppresses the header line.
-n	Sorts symbols by name.
-o	Prints value and size fields in octal.
-p	Prints symbols as a series of <code>: :nmadd</code> commands. This option can be used with <code>-P</code> to produce a macro file that can be subsequently read into the debugger with <code>\$<</code> .
-u	Prints only undefined symbols.
-v	Sorts symbols by value.
-x	Prints value and size fields in hexadecimal.
-t <i>type</i> [, <i>type</i> ...]	Prints only symbols of the specified type(s). The valid <i>type</i> argument strings are: noty STT_NOTYPE objt STT_OBJECT func STT_FUNC sect STT_SECTION file STT_FILE comm STT_COMMON tls STT_TLS regi STT_SPARC_REGISTER
-f <i>format</i> [, <i>format</i> ...]	Prints only the specified symbol information. The valid <i>format</i> argument strings are: ndx symbol table index val symbol value size size in bytes type symbol type bind binding oth other shndx section index name symbol name

`ctype` C type for symbol (if known)

`obj` object which defines symbol

`value ::nmadd [-fo] [-e end] [-s size] name`

Add the specified symbol *name* to the private symbol table. `mdb` provides a private, configurable symbol table that can be used to interpose on the target's symbol table, as described under `Symbol Name Resolution` above. The `::nmadd` dcmd also recognizes the following options:

`-e` Sets the size of the symbol to *end - value*.

`-f` Sets the type of the symbol to `STT_FUNC`.

`-o` Sets the type of the symbol to `STT_OBJECT`.

`-s` Sets the size of the symbol to *size*.

`::nmdelete name`

Delete the specified symbol *name* from the private symbol table.

`::objects`

Print a map of the target's virtual address space, showing only those mappings that correspond to the primary mapping (usually the text section) of each of the known load objects.

`::offsetof type member`

Print the offset of the specified *member* of the specified *type*. The *type* should be the name of a C structure. The offset is printed in bytes, unless the member is a bit-field, in which case the offset may be printed in bits. The output is always suffixed with the appropriate units for clarity. The type name may use the backquote (``) scoping operator described under `Symbol Name Resolution`, above. The `::offsetof` dcmd may only be used with objects that contain symbolic debugging information designed for use with `mdb`. Refer to `NOTES, Symbolic Debugging Information`, below for more information.

`address ::print [-aCdLptx] [-c lim]`

`[-l lim] [type [member ...]]`

Print the data structure at the specified virtual *address* using the given *type* information. The *type* parameter may name a C struct, union, enum, fundamental integer type, or a pointer to any of these types. If the type name contains whitespace (for example, "struct foo"), it must be enclosed in single or double quotes. The type name may use the backquote (``) scoping operator described under `Symbol Name Resolution`, above. If the type is a structured type, the `::print` dcmd will recursively print each member of the struct or union. If the *type* argument is not present and a static or global `STT_OBJECT` symbol matches the address, `::print` will infer the appropriate type automatically. If the *type* argument is specified, it may be followed by an optional list of *member* expressions, in which case only those members and submembers of the specified *type* are displayed. If *type* contains other structured types, each member string may refer to a sub-structure element by forming a list of member names separated by period (``.`) delimiters. The `::print` dcmd may only be used with objects that contain symbolic debugging information designed for use with `mdb`. Refer to `NOTES,`

mdb(1)

Symbolic Debugging Information, below for more information. After displaying the data structure, `::print` increments dot by the size of *type* in bytes.

If the `-a` option is present, the address of each member is displayed. If the `-p` option is present, `::print` interprets *address* as a physical memory address instead of a virtual memory address. If the `-t` option is present, the type of each member is displayed. If the `-d` or `-x` options are present, all integers are displayed in decimal (`-d`) or hexadecimal (`-x`). By default, a heuristic is used to determine if the value should be displayed in decimal or hexadecimal. The number of characters in a character array that will be read and displayed as a string can be limited with the `-c` option. If the `-C` option is present, no limit is enforced. The number of elements in a standard array that will be read and displayed can be limited with the `-l` option. If the `-L` option is present, no limit is enforced and all array elements are shown. The default values for `-c` and `-l` can be modified using `::set` or the `-o` command-line option as described under `OPTIONS`, below.

`::quit`

`$q`

Quit the debugger.

`[thread] ::regs`

`[thread] $r`

Print the general purpose register set of the representative thread. If a thread is specified, the general purpose register set of that thread is displayed. The thread expression should be one of the thread identifiers described under `Thread Support`, above.

`::release [-a]`

`:R [-a]`

Release the previously attached process or core file. If the `-a` option is present, the process is released and left stopped and abandoned. It can subsequently be continued by `prun(1)` (see `proc(1)`) or it can be resumed by applying `mdb` or another debugger. By default, a released process is forcibly terminated if it was created by `mdb` using `::run`, or it is released and set running if it was attached to by `mdb` using the `-p` option or using the `::attach` or `:A dcmds`.

`::run [args ...]`

`:r [args ...]`

Start a new target program running with the specified arguments and attach to it. The arguments are not interpreted by the shell. If the debugger is already examining a live running program, it will first detach from this program as if by `::release`.

`::set [-wF] [+/-o option] [-s distance] [-I path]`

`[-L path] [-P prompt]`

Get or set miscellaneous debugger properties. If no options are specified, the current set of debugger properties is displayed. The `::set` dcmd recognizes the following options:

`-F` Forcibly takes over the next user process that `::attach` is applied to, as if `mdb` had been executed with the `-F` option on the command line.

- I Sets the default path for locating macro files. The path argument may contain any of the special tokens described for the -I command-line option under OPTIONS below.
- L Sets the default path for locating debugger modules. The path argument may contain any of the special tokens described for the -I command-line option under OPTIONS below.
- o Enables the specified debugger option. If the +o form is used, the option is disabled. The option strings are described along with the -o command-line option under OPTIONS below.
- P Sets the command prompt to the specified prompt string.
- s Sets the symbol matching distance to the specified distance. Refer to the description of the -s command-line option under OPTIONS below for more information.
- w Re-opens the target for writing, as if mdb had been executed with the -w option on the command line.

`[signal] ::sigbp [+/-dDestT] [-c cmd] [-n count] SIG ...`

`[signal] :t [+/-dDestT] [-c cmd] [-n count] SIG ...`

Trace delivery of the specified signals. The signals are identified using an optional signal number preceding the `dcmd`, or a list of signal names or numbers (see `signal(3HEAD)`) following the `dcmd`. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset dcmd`. Initially, the set of signals that cause the process to dump core by default (see `signal(3HEAD)`) and `SIGINT` are traced.

`::sizeof type`

Print the size of the specified `type` in bytes. The `type` parameter may name a C struct, union, enum, fundamental integer type, or a pointer to any of these types. The type name may use the backquote (``) scoping operator described under Symbol Name Resolution, above. The `::sizeof dcmd` may only be used with objects that contain symbolic debugging information designed for use with `mdb`. Refer to NOTES, Symbolic Debugging Information, below for more information.

`[address] ::stack [count]`

`[address] $c [count]`

Print a C stack backtrace. If the `dcmd` is preceded by an explicit `address`, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than `count` arguments are displayed for each stack frame in the output.

`::status`

Print a summary of information related to the current target.

`::step [over | out] [SIG]`

`:s [SIG]`

`:u [SIG]`

mdb(1)

Step the target program one instruction. If an optional signal name or number (see `signal(3HEAD)`) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If the optional "over" argument is specified, `::step` will step over subroutine calls. The `::step over` argument is the same as the `::next` dcmd. If the optional "out" argument is specified, the target program will continue until the representative thread returns from the current function. If no target program is currently running, `::step out` will start a new program running as if by `::run` and stop at the first instruction. The `::s` dcmd is the same as `::step`. The `::u` dcmd is the same as `::step out`.

`[syscall] ::sysbp [+/-dDestT] [-io] [-c cmd]
[-n count] syscall...`

Trace entry to or exit from the specified system calls. The system calls are identified using an optional system call number preceding the dcmd, or a list of system call names or numbers (see `<sys/syscall.h>`) following the dcmd. If the `-i` option is specified (the default), the event specifiers trigger on entry into the kernel for each system call. If the `-o` option is specified, the event specifiers trigger on exit out from the kernel. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset` dcmd.

`thread ::tls symbol`

Print the address of the storage for the specified thread-local storage (TLS) symbol in the context of the specified thread. The thread expression should be one of the thread identifiers described under `Thread Support`, above. The symbol name may use any of the scoping operators described under `Symbol Name Resolution`, above.

`::typeset [+/-t] variable-name . . .`

Set attributes for named variables. If one or more variable names are specified, they are defined and set to the value of dot. If the `-t` option is present, the user-defined tag associated with each variable is set. If the `+t` option is present, the tag is cleared. If no variable names are specified, the list of variables and their values is printed.

`::unload module-name`

Unload the specified dmod. The list of active dmods may be printed using the `::dmods` dcmd. Built-in modules may not be unloaded. Modules that are busy (that is, provide dcmds that are currently executing) may not be unloaded.

`::unset variable-name . . .`

Unset (remove) the specified variable(s) from the list of defined variables. Some variables exported by `mdb` are marked as persistent, and may not be unset by the user.

`::vars [-npt]`

Print a listing of named variables. If the `-n` option is present, the output is restricted to variables that currently have non-zero values. If the `-p` option is present, the variables are printed in a form suitable for re-processing by the debugger using the `$(` dcmd. This option can be used to record the variables to a

macro file and then restore these values later. If the `-t` option is present, only the tagged variables are printed. Variables can be tagged using the `-t` option of the `::typeset` dcmd.

`::version`

Print the debugger version number.

`address ::vtop [-a as]`

Print the physical address mapping for the specified virtual address, if possible.

The `::vtop` dcmd is only available when examining a kernel target, or when examining a user process inside a kernel crash dump (after a `::context` dcmd has been issued).

When examining a kernel target from the kernel context, the `-a` option can be used to specify the address (*as*) of an alternate address space structure that should be used for the virtual to physical translation. By default, the kernel's address space is used for translation. This option is available for active address spaces even when the dump content only contains kernel pages.

`[address] ::walk walker-name [variable-name]`

Walk through the elements of a data structure using the specified walker. The available walkers can be listed using the `::walkers` dcmd. Some walkers operate on a global data structure and do not require a starting address. For example, walk the list of proc structures in the kernel. Other walkers operate on a specific data structure whose address must be specified explicitly. For example, given a pointer to an address space, walk the list of segments. When used interactively, the `::walk` dcmd will print the address of each element of the data structure in the default base. The dcmd can also be used to provide a list of addresses for a pipeline. The walker name may use the backquote (```) scoping operator described under `dcmd` and `Walker Name Resolution`, above. If the optional *variable-name* is specified, the specified variable will be assigned the value returned at each step of the walk when `mdb` invokes the next stage of the pipeline.

`::walkers`

List the available walkers and print a brief description for each one.

`::whence [-v] name ...`

`::which [-v] name ...`

Print the dmod that exports the specified dcmds and walkers. These dcmds can be used to determine which dmod is currently providing the global definition of the given dcmd or walker. Refer to the section on `dcmd` and `Walker Name Resolution` above for more information on global name resolution. The `-v` option will cause the dcmd to print the alternate definitions of each dcmd and walker in order of precedence.

`addr [,len] ::wp [+/- -dDestT] [-rxw] [-c cmd] [-n count]`

`addr [,len] :a [cmd ...]`

`addr [,len] :p [cmd ...]`

`addr [,len] :w [cmd ...]`

Set a watchpoint at the specified address. The length in bytes of the watched region may be set by specifying an optional repeat count preceding the dcmd. If no length

mdb(1)

is explicitly set, the default is one byte. The `:wp` dcmd allows the watchpoint to be configured to trigger on any combination of read (`-r` option), write (`-w` option), or execute (`-x` option) access. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `:evset` dcmd. The `:a` dcmd sets a read access watchpoint at the specified address. The `:p` dcmd sets an execute access watchpoint at the specified address. The `:w` dcmd sets a write access watchpoint at the specified address. The arguments following the `:a`, `:p`, and `:w` dcmds are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

`:xdata`

List the external data buffers exported by the current target. External data buffers represent information associated with the target that can not be accessed through standard target facilities (that is, an address space, symbol table, or register set). These buffers may be consumed by dcmds; for more information, refer to the *Solaris Modular Debugger Guide*.

`:z`

Delete all event specifiers from the list of traced software events. Event specifiers can also be deleted using `:delete`.

OPTIONS

The following options are supported:

- `-A` Disables automatic loading of `mdb` modules. By default, `mdb` attempts to load debugger modules corresponding to the active shared libraries in a user process or core file, or to the loaded kernel modules in the live operating system or an operating system crash dump.
- `-f` Forces raw file debugging mode. By default, `mdb` attempts to infer whether the object and core file operands refer to a user executable and core dump or to a pair of operating system crash dump files. If the file type cannot be inferred, the debugger will default to examining the files as plain binary data. The `-f` option forces `mdb` to interpret the arguments as a set of raw files to examine.
- `-F` Forcibly takes over the specified user process, if necessary. By default, `mdb` refuses to attach to a user process that is already under the control of another debugging tool, such as `truss(1)`. With the `-F` option, `mdb` attaches to these processes anyway. This may produce unexpected interactions between `mdb` and the other tools attempting to control the process.
- `-I path` Sets default path for locating macro files. Macro files are read using the `$<` or `$<<` dcmds. The path is a sequence of directory names delimited by colon (`:`) characters. The `-I include path` and `-L library path` (see below) may also contain any of the following tokens:
 - `%i` Expands to the current instruction set architecture (ISA) name ('sparc', 'sparcv9', or 'i386').

- `%o` Expands to the old value of the path being modified. This is useful for appending or prepending directories to an existing path.
- `%p` Expands to the current platform string (either `uname -i` or the platform string stored in the process core file or crash dump).
- `%r` Expands to the pathname of the root directory. An alternate root directory may be specified using the `-R` option. If no `-R` option is present, the root directory is derived dynamically from the path to the `mdb` executable itself. For example, if `/bin/mdb` is executed, the root directory will be `/`. If `/net/hostname/bin/mdb` were executed, the root directory would be derived as `/net/hostname`.
- `%t` Expands to the name of the current target. This will either be the literal string `'proc'` (a user process or user process core file), `'kvm'` (a kernel crash dump or the live operating system), or `'raw'` (a raw file).

The default include path for 32-bit `mdb` is:

```
%r/usr/platform/%p/lib/adb:%r/usr/lib/adb
```

The default include path for 64-bit `mdb` is:

```
%r/usr/platform/%p/lib/adb/%i:%r/usr/lib/adb/%i
```

- `-k` Forces kernel debugging mode. By default, `mdb` attempts to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The `-k` option forces `mdb` to assume these files are operating system crash dump files. If no object or core operand is specified, but the `-k` option is specified, `mdb` defaults to an object file of `/dev/ksyms` and a core file of `/dev/kmem`. Access to `/dev/kmem` is restricted to group `sys`.
- `-L path` Sets default path for locating debugger modules. Modules are loaded automatically on startup or using the `::load` cmd. The path is a sequence of directory names delimited by colon (`:`) characters. The `-L` library path may also contain any of the tokens shown for `-I` above.
- `-m` Disables demand-loading of kernel module symbols. By default, `mdb` processes the list of loaded kernel modules and performs demand loading of per-module symbol tables. If the `-m` option is specified, `mdb` will not attempt to process the kernel module list or

mdb(1)

	provide per-module symbol tables. As a result, <code>mdb</code> modules corresponding to active kernel modules will not be loaded on startup.
<code>-M</code>	Preloads all kernel module symbols. By default, <code>mdb</code> performs demand-loading for kernel module symbols: the complete symbol table for a module is read when an address in that module's text or data section is referenced. With the <code>-M</code> option, <code>mdb</code> loads the complete symbol table of all kernel modules during startup.
<code>-o option</code>	Enables the specified debugger option. If the <code>+o</code> form of the option is used, the specified <i>option</i> is disabled. Unless noted below, each option is off by default. <code>mdb</code> recognizes the following <i>option</i> arguments: <code>adb</code> Enables stricter <code>adb(1)</code> compatibility. The prompt will be set to the empty string and many <code>mdb</code> features, such as the output pager, will be disabled. <code>array_mem_limit=limit</code> Sets the default limit on the number of array members that <code>::print</code> will display. If <i>limit</i> is the special token <code>none</code> , all array members will be displayed by default. <code>array_str_limit=limit</code> Sets the default limit on the number of characters that <code>::print</code> will attempt to display as an ASCII string when printing a char array. If <i>limit</i> is the special token <code>none</code> , the entire char array will be displayed as a string by default. <code>follow_exec_mode=mode</code> Sets the debugger behavior for following an <code>exec(2)</code> system call. The <i>mode</i> should be one of the following named constants: <code>ask</code> If <code>stdout</code> is a terminal device, the debugger stops after the <code>exec(2)</code> system call has returned and then prompts the user to decide whether to follow the <code>exec</code> or <code>stop</code> . If <code>stdout</code> is not a terminal device, the <code>ask</code> mode defaults to <code>stop</code> . <code>follow</code> The debugger follows the <code>exec</code> by automatically continuing the target process and resetting all of its mappings and symbol tables based on the new executable. The <code>follow</code> behavior is discussed in more detail under <code>NOTES, Interaction with Exec</code> , below. <code>stop</code> The debugger stops following return from the <code>exec</code> system call. The <code>stop</code> behavior is discussed in more detail under <code>NOTES, Interaction with Exec</code> , below.

follow_fork_mode=mode

Sets the debugger behavior for following a `fork(2)`, `fork1(2)`, or `vfork(2)` system call. The *mode* should be one of the following named constants:

- ask** If stdout is a terminal device, the debugger stops after the `fork(2)` system call has returned and then prompts the user to decide whether to follow the parent or child. If stdout is not a terminal device, the `ask` mode defaults to parent.
- parent** The debugger follows the parent process, and detaches from the child process and sets it running.
- child** The debugger follows the child process, and detaches from the parent process and sets it running.

ignoreeof

The debugger will not exit when an EOF sequence (^D) is entered at the terminal. The `::quit` dcmd must be used to quit.

nostop

Does not stop a user process when attaching to it when the `-p` option is specified or when the `::attach` or `:A` dcmds are applied. The `nostop` behavior is described in more detail under NOTES, Process Attach and Release, below.

pager

Enables the output pager (default).

repeatlast

If a NEWLINE is entered as the complete command at the terminal, `mdb` repeats the previous command with the current value of dot. This option is implied by `-o adb`.

showlmid

`mdb` provides support for symbol naming and identification in user applications that make use of link maps other than `LM_ID_BASE` and `LM_ID_LDSO`, as described in Symbol Name Resolution, above. Symbols on link maps other than `LM_ID_BASE` or `LM_ID_LDSO` will be shown as `LMlmid`library`symbol`, where `lmid` is the link-map ID in the default output radix (16). The user may optionally configure `mdb` to show the link-map ID scope of all symbols and objects, including those associated with `LM_ID_BASE` and `LM_ID_LDSO`, by enabling the `showlmid` option. Built-in dcmds that deal with object file names will display link-map IDs according to the value of `showlmid` above, including `::nm`, `::mappings`, `$m`, and `::objects`.

mdb(1)

-p <i>pid</i>	Attaches to and stops the specified process-id. mdb will use the <code>/proc/<i>pid</i>/object/a.out</code> file as the executable file pathname.
-P <i>prompt</i>	Sets the command prompt. The default prompt is <code>'>'</code> .
-R <i>root</i>	Sets root directory for pathname expansion. By default, the root directory is derived from the pathname of the mdb executable itself. The root directory is substituted in place of the <code>%r</code> token during pathname expansion.
-s <i>distance</i>	Sets the symbol matching distance for address-to-symbol-name conversions to the specified <i>distance</i> . By default, mdb sets the distance to zero, which enables a smart-matching mode. Each ELF symbol table entry includes a value <i>V</i> and size <i>S</i> , representing the size of the function or data object in bytes. In smart mode, mdb matches an address <i>A</i> with the given symbol if <i>A</i> is in the range <code>[V, V + S)</code> . If any non-zero distance is specified, the same algorithm is used, but <i>S</i> in the expression above is always the specified absolute distance and the symbol size is ignored.
-S	Suppresses processing of the user's <code>~/ .mdbContext</code> file. By default, mdb reads and processes the macro file <code>.mdbContext</code> if one is present in the user's home directory, as defined by <code>\$HOME</code> . If the <code>-S</code> option is present, this file will not be read.
-u	Forces user debugging mode. By default, mdb attempts to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The <code>-u</code> option forces mdb to assume these files are not operating system crash dump files.
-V <i>version</i>	Sets disassembler version. By default, mdb attempts to infer the appropriate disassembler version for the debug target. The disassembler can be set explicitly using the <code>-V</code> option. The <code>::disasms dcmd</code> lists the available disassembler versions.
-w	Opens the specified object and core files for writing.
-y	Sends explicit terminal initialization sequences for tty mode. Some terminals, such as <code>cmdt001(1)</code> , require explicit initialization sequences to switch into a tty mode. Without this initialization sequence, terminal features such as standout mode may not be available to mdb.

OPERANDS The following operands are supported:

<i>object</i>	Specifies an ELF format object file to examine. mdb provides the ability to examine and edit ELF format executables (<code>ET_EXEC</code>), ELF dynamic library files (<code>ET_DYN</code>), ELF relocatable object files (<code>ET_REL</code>), and operating system <code>unix.X</code> symbol table files.
---------------	---

	<i>core</i>	Specifies an ELF process core file (ET_CORE), or an operating system crash dump vmcore.X file. If an ELF core file operand is provided without a corresponding object file, mdb will attempt to infer the name of the executable file that produced the core using several different algorithms. If no executable is found, mdb will still execute, but some symbol information may be unavailable.
	<i>suffix</i>	Specifies the numerical suffix representing a pair of operating system crash dump files. For example, if the suffix is '3', mdb infers that it should examine the files 'unix.3' and 'vmcore.3'. The string of digits will not be interpreted as a suffix if an actual file of the same name is present in the current directory.
USAGE		mdb processes all input files (including scripts, object files, core files, and raw data files) in a large file aware fashion. See <code>largefile(5)</code> for more information about the processing of large files, which are files greater than or equal to 2 Gbytes (2 ³¹ bytes).
EXIT STATUS		The following exit values are returned:
	0	Debugger completed execution successfully.
	1	A fatal error occurred.
	2	Invalid command line options were specified.
ENVIRONMENT VARIABLES	<i>HISTSIZE</i>	This variable is used to determine the maximum length of the command history list. If this variable is not present, the default length is 128.
	<i>HOME</i>	This variable is used to determine the pathname of the user's home directory, where a <code>.mdbContext</code> file may reside. If this variable is not present, no <code>.mdbContext</code> processing will occur.
	<i>SHELL</i>	This variable is used to determine the pathname of the shell used to process shell escapes requested using the ! meta-character. If this variable is not present, <code>/bin/sh</code> is used.
FILES	<code>\$HOME/.mdbContext</code>	User mdb initialization file. The <code>.mdbContext</code> file, if present, is processed after the debug target has been initialized, but before module auto-loading is performed or any commands have been read from standard input.
	<code>/dev/kmem</code>	Kernel virtual memory image device. This device special file is used as the core file when examining the live operating system.
	<code>/dev/ksyms</code>	Kernel symbol table device. This device special file is used as the object file when examining the live operating system.
	<code>/proc/pid/*</code>	Process information files that are read when examining and controlling user processes.

mdb(1)

/usr/lib/adb

/usr/platform/*platform-name*/lib/adb

Default directories for macro files that are read with the `$<` and `$<<` dcmds.

platform-name is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see `uname(1)`).

/usr/lib/mdb

/usr/platform/*platform-name*/lib/mdb

Default directories for debugger modules that are loaded using the `::load` dcmd.

platform-name is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see `uname(1)`).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

Linker and Libraries Guide

Solaris Modular Debugger Guide

Use of the Error Recovery Mechanism

The debugger and its dmods execute in the same address space, and thus it is quite possible that a buggy dmod can cause `mdb` to dump core or otherwise misbehave. The `mdb` resume capability, described above under `Signal Handling`, provides a limited recovery mechanism for these situations. However, it is not possible for `mdb` to know definitively whether the dmod in question has corrupted only its own state, or the debugger's global state. Therefore a resume operation cannot be guaranteed to be safe, or to prevent a subsequent crash of the debugger. The safest course of action following a resume is to save any important debug information, and then quit and restart the debugger.

Use of the Debugger to Modify the Live Operating System

The use of the debugger to modify (that is, write to) the address space of live running operating system is extremely dangerous, and may result in a system panic in the event the user damages a kernel data structure.

**Limitations on
Examining Process
Core Files**

mdb does not provide support for examining process core files that were generated by a release of Solaris preceding Solaris 2.6. If a core file from one operating system release is examined on a different operating system release, the run-time link-editor debugging interface (`librtld_db`) may not be able to initialize. In this case, symbol information for shared libraries will not be available. Furthermore, since shared mappings are not present in user core files, the text section and read-only data of shared libraries may not match the data that was present in the process at the time it dumped core. Core files from Solaris Intel systems may not be examined on Solaris SPARC systems, and vice-versa.

**Limitations on
Examining Crash
Dump Files**

Crash dumps from Solaris 7 and earlier releases may only be examined with the aid of the `libkvm` from the corresponding operating system release. If a crash dump from one operating system release is examined using the `dmods` from a different operating system release, changes in the kernel implementation may prevent some `dcmds` or `walkers` from working properly. `mdb` will issue a warning message if it detects this condition. Crash dumps from Solaris Intel systems may not be examined on Solaris SPARC systems, and vice-versa.

**Relationship
Between 32-bit and
64-bit Debugger**

`mdb` provides support for debugging both 32-bit and 64-bit programs. Once it has examined the target and determined its data model, `mdb` automatically re-executes the `mdb` binary that has the same data model as the target, if necessary. This approach simplifies the task of writing debugger modules, because the modules that are loaded will use the same data model as the primary target. Only the 64-bit debugger may be used to debug 64-bit target programs. The 64-bit debugger can only be used on a system that is running the 64-bit operating environment.

The debugger may also need to re-execute itself when debugging a 32-bit process that execs a 64-bit process, or vice-versa. The handling of this situation is discussed in more detail under `Interaction with Exec`, below.

**Interaction with
Exec**

When a controlled process performs a successful `exec(2)`, the behavior of the debugger is controlled by the `::set -o follow_exec_mode` option, as described above. If the debugger and victim process have the same data model, then the `"stop"` and `"follow"` modes determine whether `mdb` automatically continues the target or returns to the debugger prompt following the `exec`. If the debugger and victim process have a different data model, then the `"follow"` behavior causes `mdb` to automatically re-exec the `mdb` binary with the appropriate data model and to re-attach to the process, still stopped on return from the `exec`. Not all debugger state is preserved across this re-exec.

If a 32-bit victim process execs a 64-bit program, then `"stop"` returns to the command prompt, but the debugger is no longer able to examine the process because it is now using the 64-bit data model. To resume debugging, execute the `::release -a dcmd`, quit `mdb`, and then execute `mdb -p pid` to re-attach the 64-bit debugger to the process.

mdb(1)

	<p>If a 64-bit victim process execs a 32-bit program, then "stop" will return to the command prompt, but the debugger will only provide limited capabilities for examining the new process. All built-in dcmds will work as advertised, but loadable dcmds will not since they do not perform data model conversion of structures. The user should release and re-attach the debugger to the process as described above in order to restore full debugging capabilities.</p>
Interaction with Job Control	<p>If the debugger is attached to a process that is stopped by job control (that is, it stopped in response to SIGTSTP, SIGTTIN, or SIGTTOU), the process may not be able to be set running again when it is continued by a continue dcmd. If the victim process is a member of the same session (that is, it shares the same controlling terminal as mdb), mdb attempts to bring the associated process group to the foreground and to continue the process with SIGCONT to resume it from job control stop. When mdb is detached from such a process, it restores the process group to the background before exiting. If the victim process is not a member of the same session, mdb cannot safely bring the process group to the foreground, so it continues the process with respect to the debugger, but the process remains stopped by job control. mdb prints a warning in this case, and the user must issue an "fg" command from the appropriate shell in order to resume the process.</p>
Process Attach and Release	<p>When mdb attaches to a running process, the process is stopped and remains stopped until one of the continue dcmds is applied, or the debugger quits. If the -o nostop option is enabled prior to attaching the debugger to a process with -p, or prior to issuing an ::attach or :A command, mdb attaches to the process but does not stop it. While the process is still running, it may be inspected as usual (albeit with inconsistent results) and breakpoints or other tracing flags may be enabled. If the :c or ::cont dcmds are executed while the process is running, the debugger waits for the process to stop. If no traced software events occur, the user can send an interrupt (^C) after :c or ::cont to force the process to stop and return control to the debugger.</p> <p>mdb releases the current running process (if any) when the :R, ::release, :r, ::run, \$q, or ::quit dcmds are executed, or when the debugger terminates as the result of an EOF or signal. If the process was originally created by the debugger using :r or ::run, it will be forcibly terminated as if by SIGKILL when it is released. If the process was already running prior to attaching mdb to it, it will be set running again when it is released. A process may be released and left stopped and abandoned using the ::release -a option.</p>
Symbolic Debugging Information	<p>The ::list, ::offsetof, ::print, and ::sizeof dcmds require that one or more load objects contain compressed symbolic debugging information suitable for use with mdb. This information is currently only available for certain Solaris kernel modules.</p>
Developer Information	<p>The <i>Solaris Modular Debugger Guide</i> provides a more detailed description of mdb features, as well as information for debugger module developers.</p> <p>The header file <sys/mdb_modapi.h> contains prototypes for the functions in the MDB Module API, and the SUNWmdbdm package provides source code for an example module in the directory /usr/demo/mdb.</p>

NAME	mesg – permit or deny messages						
SYNOPSIS	mesg [-n -y n y]						
DESCRIPTION	The <code>mesg</code> utility will control whether other users are allowed to send messages via <code>write(1)</code> , <code>talk(1)</code> , or other utilities to a terminal device. The terminal device affected is determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, <code>mesg</code> reports the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.						
OPTIONS	The following options are supported: -n n Denies permission to other users to send message to the terminal. See <code>write(1)</code> . -y y Grants permission to other users to send messages to the terminal.						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>mesg</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS	The following exit values are returned: 0 if messages are receivable. 1 if messages are not receivable. 2 on error.						
FILES	/dev/tty* terminal devices /dev/pts/* terminal devices						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>Interface Stability</td> <td>Standard</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	Interface Stability	Standard
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWcsu						
Interface Stability	Standard

message(1F)

NAME	message – puts its arguments on FMLI message line
SYNOPSIS	message [-t] [-b <i>num</i>] [-o] [-w] [<i>string</i>] message [-f] [-b <i>num</i>] [-o] [-w] [<i>string</i>] message [-p] [-b <i>num</i>] [-o] [-w] [<i>string</i>]
DESCRIPTION	<p>The message command puts <i>string</i> out on the FMLI message line. If there is no string, the <i>stdin</i> input to message will be used. The output of message has a duration (length of time it remains on the message line). The default duration is "transient": it or one of two other durations can be requested with the mutually-exclusive options below.</p> <p>Messages displayed with message -p will replace (change the value of) any message currently displayed or stored via use of the permanentmsg descriptor. Likewise, message -f will replace any message currently displayed or stored via use of the framemsg descriptor. If more than one message in a frame definition file is specified with the -p option, the last one specified will be the permanent duration message.</p> <p>The <i>string</i> argument should always be the last argument.</p>
OPTIONS	<p>-t Explicitly defines a message to have transient duration. Transient messages remain on the message line only until the user presses another key or a CHECKWORLD occurs. The descriptors itemmsg , fieldmsg , invalidmsg , choicemsg , the default-if-not-defined value of oninterrupt , and FMLI generated error messages (that is, from syntax errors) also output transient duration messages. Transient messages take precedence over both frame messages and permanent messages.</p> <p>-f Defines a message to have "frame" duration. Frame messages remain on the message line as long as the frame in which they are defined is current. The descriptor framemsg also outputs a frame duration message. Frame messages take precedence over permanent messages.</p> <p>-p Defines a message to have "permanent" duration. Permanent messages remain on the message line for the length of the FMLI session, unless explicitly replaced by another permanent message or temporarily superseded by a transient message or frame message. A permanent message is not affected by navigating away from, or by closing, the frame which generated the permanent message. The descriptor permanentmsg also outputs a permanent duration message.</p> <p>-b<i>num</i> Rings the terminal bell <i>num</i> times, where <i>num</i> is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen will flash <i>num</i> times instead, if possible.</p> <p>-o Forces message to duplicate its message to <i>stdout</i> .</p> <p>-w Turns on the working indicator.</p>

EXAMPLES **EXAMPLE 1** A sample output of message on the message line:

When a value entered in a field is invalid, ring the bell 3 times and then display Invalid Entry: Try again! on the message line:

```
invalidmsg=`message -b 3 "Invalid Entry: Try again!"`
```

Display a message that tells the user what is being done:

```
done=`message EDITOR has been set in your environment` close
```

Display a message on the message line and *stdout* for each field in a form (a pseudo-"field duration" message).

```
fieldmsg=`message -o -f "Enter a filename."`
```

Display a blank transient message (effect is to "remove" a permanent or frame duration message).

```
done=`message ""` nop
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `sleep(1)`, `attributes(5)`

NOTES If `message` is coded more than once on a single line, it may appear that only the right-most instance is interpreted and displayed. Use `sleep(1)` between uses of `message` in this case, to display multiple messages.

`message -f` should not be used in a stand-alone backquoted expression or with the `init` descriptor because the frame is not yet current when these are evaluated.

In cases where ``message -f "string" `` is part of a stand-alone backquoted expression, the context for evaluation of the expression is the previously current frame. The previously current frame can be the frame that issued the `open` command for the frame containing the backquoted expression, or it can be a frame given as an argument when `fml i` was invoked. That is, the previously current frame is the one whose frame `message` will be modified.

Permanent duration messages are displayed when the user navigates to the command line.

mixerctl(1)

NAME	mixerctl – audio mixer control command line application
SYNOPSIS	<code>/usr/sbin/mixerctl [-a -d <i>dev</i>] [-iv] [-e -o]</code>
DESCRIPTION	Some audio devices support the audio mixer functionality. See <code>mixer(7I)</code> for a complete description of the audio mixer. The <code>mixerctl</code> command is used to control the mode of the audio mixer and to get information about the audio mixer and the audio device. See <code>audio(7I)</code> for details.
OPTIONS	<p>The following options are supported. If none are specified, option <code>-i</code> is assumed:</p> <ul style="list-style-type: none"><code>-a</code> The command applies to all audio devices.<code>-d <i>dev</i></code> The <i>dev</i> argument specifies an alternate audio control device for the command to use.<code>-e</code> Enables the audio mixer function if the audio device supports it. If supported, the audio mixer may be enabled at any time. The command silently ignores the enable option if the audio mixer is already enabled.<code>-i</code> Prints the audio device type information for the device and indicates whether the audio device uses the audio mixer. If the device does use the audio mixer, this option displays the audio mixer's mode.<code>-o</code> Turns off the audio mixer function if the audio device supports it. If supported, the audio mixer may be turned off if only one process has the device opened with the <code>O_RDWR</code> flag, or, if two different processes have the device opened, one with the <code>O_RDONLY</code> flag and the other with the <code>O_WRONLY</code> flag. (See <code>open(2)</code>.) The command silently ignores the disable option if the audio mixer function is already disabled.<code>-v</code> Verbose mode. Prints the <code>audio_info_t</code> structure for the device, along with the device type information. This option implies the <code>-i</code> option.
ENVIRONMENT VARIABLES	<p><code>AUDIODEV</code> If the <code>-d</code> and <code>-a</code> options are not specified, the <code>AUDIODEV</code> environment variable is consulted. If set, <code>AUDIODEV</code> will contain the full path name of the user's default audio device. The default audio device will be converted into a control device, and then used. If the <code>AUDIODEV</code> variable is not set, <code>/dev/audioctl</code> is used.</p>
FILES	<p><code>/dev/audioctl</code></p> <p><code>/dev/sound/{0..n}ctl</code></p>

mkdir(1)

NAME	mkdir – make directories
SYNOPSIS	mkdir [-m <i>mode</i>] [-p] <i>dir</i> ...
DESCRIPTION	<p>The mkdir command creates the named directories in mode 777 (possibly altered by the file mode creation mask <code>umask(1)</code>).</p> <p>Standard entries in a directory (for instance, the files “.”, for the directory itself, and “..”, for its parent) are made automatically. mkdir cannot create these entries by name. Creation of a directory requires write permission in the parent directory.</p> <p>The owner-ID and group-ID of the new directories are set to the process’s effective user-ID and group-ID, respectively. mkdir calls the <code>mkdir(2)</code> system call.</p>
setgid and mkdir	<p>To change the <code>setgid</code> bit on a newly created directory, you must use <code>chmod g+s</code> or <code>chmod g-s</code> after executing mkdir.</p> <p>The <code>setgid</code> bit setting is inherited from the parent directory.</p>
OPTIONS	<p>The following options are supported:</p> <p>-m <i>mode</i> This option allows users to specify the mode to be used for new directories. Choices for modes can be found in <code>chmod(1)</code>.</p> <p>-p With this option, mkdir creates <i>dir</i> by creating all the non-existing parent directories first. The mode given to intermediate directories will be the difference between 777 and the bits set in the file mode creation mask. The difference, however, must be at least 300 (write and execute permission for the user).</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>dir</i> A path name of a directory to be created.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of mkdir when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
EXAMPLES	<p>EXAMPLE 1 Using mkdir</p> <p>The following example:</p> <pre>example% mkdir -p ltr/jd/jan</pre> <p>creates the subdirectory structure <code>ltr/jd/jan</code>.</p>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of mkdir : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 All the specified directories were created successfully or the <code>-p</code> option was specified and all the specified directories now exist.</p>

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

mkmsgs(1)

NAME	mkmsgs – create message files for use by gettext
SYNOPSIS	mkmsgs [-o] [-i <i>locale</i>] <i>inputstrings</i> <i>msgfile</i>
DESCRIPTION	<p>The <code>mkmsgs</code> utility is used to create a file of text strings that can be accessed using the text retrieval tools (see <code>gettext(1)</code>, <code>srchtxt(1)</code>, <code>exstr(1)</code>, and <code>gettext(3C)</code>). It will take as input a file of text strings for a particular geographic locale (see <code>setlocale(3C)</code>) and create a file of text strings in a format that can be retrieved by both <code>gettext(1)</code> and <code>gettext(3C)</code>. By using the <code>-i</code> option, you can install the created file under the <code>/usr/lib/locale/locale/LC_MESSAGES</code> directory (<code>locale</code> corresponds to the language in which the text strings are written).</p> <p><i>inputstrings</i> is the name of the file that contains the original text strings. <i>msgfile</i> is the name of the output file where <code>mkmsgs</code> writes the strings in a format that is readable by <code>gettext(1)</code> and <code>gettext(3C)</code>. The name of <i>msgfile</i> can be up to 14 characters in length, but may not contain either <code>\0</code> (null) or the ASCII code for <code>/</code> (slash) or <code>:</code> (colon).</p> <p>The input file contains a set of text strings for the particular geographic locale. Text strings are separated by a newline character. Nongraphic characters must be represented as alphabetic escape sequences. Messages are transformed and copied sequentially from <i>inputstrings</i> to <i>msgfile</i>. To generate an empty message in <i>msgfile</i>, leave an empty line at the correct place in <i>inputstrings</i>.</p> <p>Strings can be changed simply by editing the file <i>inputstrings</i>. New strings must be added only at the end of the file; then a new <i>msgfile</i> file must be created and installed in the correct place. If this procedure is not followed, the retrieval function will retrieve the wrong string and software compatibility will be broken.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-o</code> Overwrite <i>msgfile</i>, if it exists.<code>-i locale</code> Install <i>msgfile</i> in the <code>/usr/lib/locale/locale/LC_MESSAGES</code> directory. Only someone who is super user or a member of group <code>bin</code> can create or overwrite files in this directory. Directories under <code>/usr/lib/locale</code> will be created if they do not exist.
EXAMPLES	<p>EXAMPLE 1 Using the <code>mkmsgs</code> command.</p> <p>The following example shows an input message source file <code>C.str</code>:</p> <pre>File %s:\t cannot be opened\n %s: Bad directory\n . . . write error\n . .</pre>

EXAMPLE 1 Using the `mkmsgs` command. (Continued)

EXAMPLE 2 Using Input Strings From `C.str` to Create Text Strings in a File

The following command uses the input strings from `C.str` to create text strings in the appropriate format in the file `UX` in the current directory:

```
example% mkmsgs C.str UX
```

EXAMPLE 3 Using Input Strings From `FR.str` to Create Text Strings in a File

The following command uses the input strings from `FR.str` to create text strings in the appropriate format in the file `UX` in the directory

```
/usr/lib/locale/fr/LC_MESSAGES:
```

```
example% mkmsgs -i fr FR.str UX
```

These text strings would be accessed if you had set the environment variable `LC_MESSAGES=fr` and then invoked one of the text retrieval tools listed at the beginning of the `DESCRIPTION` section.

FILES `/usr/lib/locale/locale/LC_MESSAGES/*`
message files created by `mkmsgs`

mkstr(1B)

NAME	mkstr – create an error message file by massaging C source files
SYNOPSIS	<code>/usr/ucb/mkstr [-] messagefile prefix filename...</code>
DESCRIPTION	<p>The <code>mkstr</code> utility creates files of error messages. You can use <code>mkstr</code> to make programs with large numbers of error diagnostics much smaller, and to reduce system overhead in running the program — as the error messages do not have to be constantly swapped in and out.</p> <p><code>mkstr</code> processes each of the specified <i>filenames</i>, placing a massaged version of the input file in a file with a name consisting of the specified <i>prefix</i> and the original source file name. A typical example of using <code>mkstr</code> would be:</p> <pre>mkstr pistrings processed *.c</pre> <p>This command would cause all the error messages from the C source files in the current directory to be placed in the file <code>pistrings</code> and processed copies of the source for these files to be placed in files whose names are prefixed with <i>processed</i>.</p> <p>To process the error messages in the source to the message file, <code>mkstr</code> keys on the string <code>'error ('</code> in the input stream. Each time it occurs, the C string starting at the <code>'</code> is placed in the message file followed by a null character and a NEWLINE character; the null character terminates the message so it can be easily used when retrieved, the NEWLINE character makes it possible to sensibly <code>cat</code> the error message file to see its contents. The massaged copy of the input file then contains a <code>lseek</code> pointer into the file which can be used to retrieve the message, that is:</p> <pre>char efilename[] = "/usr/lib/pi_strings"; int efil = -1; error(a1, a2, a3, a4) { char buf[256]; if (efil < 0) { efil = open(efilename, 0); if (efil < 0) { oops: perror (efilename); exit (1); } } if (lseek(efil, (long) a1, 0) read(efil, buf, 256) <= 0) goto oops; printf(buf, a2, a3, a4); } </pre>
OPTIONS	– Place error messages at the end of the specified message file for recompiling part of a large <code>mkstr</code> red program.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

more(1)

NAME	more, page – browse or page through a text file
SYNOPSIS	<pre>/usr/bin/more [-cdfllrsuw] [-lines] [+ <i>linenumber</i>] [+/<i> pattern</i>] [<i>file...</i>] /usr/bin/page [-cdfllrsuw] [-lines] [+ <i>linenumber</i>] [+/<i> pattern</i>] [<i>file...</i>] /usr/xpg4/bin/more [-cdeisu] [-n <i>number</i>] [-p <i>command</i>] [-t <i>tagstring</i>] [<i>file...</i>] /usr/xpg4/bin/more [-cdeisu] [-n <i>number</i>] [+ <i>command</i>] [-t <i>tagstring</i>] [<i>file...</i>]</pre>
DESCRIPTION	<p>The more utility is a filter that displays the contents of a text file on the terminal, one screenful at a time. It normally pauses after each screenful. <code>/usr/bin/more</code> then prints <code>--More--</code> and <code>/usr/xpg4/bin/more</code> then prints <i>file</i> at the bottom of the screen. If more is reading from a file rather than a pipe, the percentage of characters displayed so far is also shown.</p> <p>The more utility scrolls up to display one more line in response to a RETURN character. more displays another screenful in response to a SPACE character. Other commands are listed below.</p> <p>The page utility clears the screen before displaying the next screenful of text. page only provides a one-line overlap between screens.</p> <p>The more utility sets the terminal to NOECHO mode, so that the output can be continuous. Commands that you type do not normally show up on your terminal, except for the / and ! commands.</p> <p>The <code>/usr/bin/more</code> utility exits after displaying the last specified file. <code>/usr/xpg4/bin/more</code> prompts for a command at the last line of the last specified file.</p> <p>If the standard output is not a terminal, more acts just like <code>cat(1)</code>, except that a header is printed before each file in a series.</p>
OPTIONS	<p>The following options are supported for both <code>/usr/bin/more</code> and <code>/usr/xpg4/bin/more</code>:</p> <ul style="list-style-type: none">-c Clears before displaying. Redraws the screen instead of scrolling for faster displays. This option is ignored if the terminal does not have the ability to clear to the end of a line.-d Displays error messages rather than ringing the terminal bell if an unrecognized command is used. This is helpful for inexperienced users.-s Squeeze. Replaces multiple blank lines with a single blank line. This is helpful when viewing <code>nroff(1)</code> output on the screen.
/usr/bin/more	The following options are supported for <code>/usr/bin/more</code> only:

-f	Does not fold long lines. This is useful when lines contain nonprinting characters or escape sequences, such as those generated when <code>nroff(1)</code> output is piped through <code>ul(1)</code> .
-l	Does not treat FORMFEED characters (Control-I) as page breaks. If <code>-l</code> is not used, <code>more</code> pauses to accept commands after any line containing a ^L character (Control-I). Also, if a file begins with a FORMFEED, the screen is cleared before the file is printed.
-r	Normally, <code>more</code> ignores control characters that it does not interpret in some way. The <code>-r</code> option causes these to be displayed as ^C where C stands for any such control character.
-u	Suppresses generation of underlining escape sequences. Normally, <code>more</code> handles underlining, such as that produced by <code>nroff(1)</code> , in a manner appropriate to the terminal. If the terminal can perform underlining or has a stand-out mode, <code>more</code> supplies appropriate escape sequences as called for in the text file.
-w	Normally, <code>more</code> exits when it comes to the end of its input. With <code>-w</code> , however, <code>more</code> prompts and waits for any key to be struck before exiting.
-lines	Displays the indicated number of <i>lines</i> in each screenful, rather than the default (the number of lines in the terminal screen less two).
+linenumber	Start up at <i>linenumber</i> .
+ /pattern	Start up two lines above the line containing the regular expression <i>pattern</i> . <i>Note</i> : Unlike editors, this construct should <i>not</i> end with a <i>'/'</i> . If it does, then the trailing slash is taken as a character in the search pattern.

/usr/xpg4/bin/more

The following options are supported for `/usr/xpg4/bin/more` only:

-e	Exits immediately after writing the last line of the last file in the argument list.
-i	Performs pattern matching in searches without regard to case.
-n <i>number</i>	Specifies the number of lines per screenful. The <i>number</i> argument is a positive decimal integer. The <code>-n</code> option overrides any values obtained from the environment.
-p <i>command</i> + <i>command</i>	For each file examined, initially executes the <code>more</code> command in the <i>command</i> argument. If the command is a positioning command, such as a line number or a regular expression search, set the current position to represent the final results of the command, without writing any intermediate lines of the file. For example, the two commands:

more(1)

```
more -p 1000j file
more -p 1000G file
```

are equivalent and start the display with the current position at line 1000, bypassing the lines that *j* would write and scroll off the screen if it had been issued during the file examination. If the positioning command is unsuccessful, the first line in the file will be the current position.

-t tagstring Writes the screenful of the file containing the tag named by the *tagstring* argument. See the `ctags(1)` utility.

-u Treats a backspace character as a printable control character, displayed as a `^H` (Control-h), suppressing backspacing and the special handling that produces underlined or standout-mode text on some terminal types. Also, does not ignore a carriage-return character at the end of a line.

If both the *-t tagstring* and *-p command* (or the obsolescent *+command*) options are given, the *-t tagstring* is processed first.

Environment `more` uses the terminal's `terminfo(4)` entry to determine its display characteristics.

`more` looks in the environment variable `MORE` for any preset options. For instance, to page through files using the *-c* mode by default, set the value of this variable to *-c*. (Normally, the command sequence to set up this environment variable is placed in the `.login` or `.profile` file).

Commands The commands take effect immediately. It is not necessary to type a carriage return unless the command requires a *file*, *command*, *tagstring*, or *pattern*. Up to the time when the command character itself is given, the user may type the line kill character to cancel the numerical argument being formed. In addition, the user may type the erase character to redisplay the `'--More-- (xx%)'` or *file* message.

In the following commands, *i* is a numerical argument (1 by default).

*i*SPACE Display another screenful, or *i* more lines if *i* is specified.

*i*RETURN Display another line, or *i* more lines, if specified.

*i*b
i^B (Control-b) Skip back *i* screenfuls and then print a screenful.

*i*d
i^D (Control-d) Scroll forward one half screenful or *i* more lines. If *i* is specified, the count becomes the default for subsequent *d* and *u* commands.

*i*f Skip *i* screens full and then print a screenful.

h Help. Give a description of all the `more` commands.

^L (Control-l) Refresh.

<i>in</i>	Search for the <i>i</i> th occurrence of the last <i>pattern</i> entered.
<i>q</i> <i>Q</i>	Exit from <i>more</i> .
<i>is</i>	Skip <i>i</i> lines and then print a screenful.
<i>v</i>	Drop into the <i>vi</i> editor at the current line of the current file.
<i>iz</i>	Same as <i>SPACE</i> , except that <i>i</i> , if present, becomes the new default number of lines per screenful.
<i>=</i>	Display the current line number.
<i>i/pattern</i>	Search forward for the <i>i</i> th occurrence of the regular expression <i>pattern</i> . Display the screenful starting two lines before the line that contains the <i>i</i> th match for the regular expression <i>pattern</i> , or the end of a pipe, whichever comes first. If <i>more</i> is displaying a file and there is no match, its position in the file remains unchanged. Regular expressions can be edited using erase and kill characters. Erasing back past the first column cancels the search command.
<i>!command</i>	Invoke a shell to execute <i>command</i> . The characters <i>%</i> and <i>!</i> , when used within <i>command</i> are replaced with the current filename and the previous shell command, respectively. If there is no current filename, <i>%</i> is not expanded. Prepend a backslash to these characters to escape expansion.
<i>:f</i>	Display the current filename and line number.
<i>i:n</i>	Skip to the <i>i</i> th next filename given in the command line, or to the last filename in the list if <i>i</i> is out of range.
<i>i:p</i>	Skip to the <i>i</i> th previous filename given in the command line, or to the first filename if <i>i</i> is out of range. If given while <i>more</i> is positioned within a file, go to the beginning of the file. If <i>more</i> is reading from a pipe, <i>more</i> simply rings the terminal bell.
<i>:q</i> <i>:Q</i>	Exit from <i>more</i> (same as <i>q</i> or <i>Q</i>).
/usr/bin/more	The following commands are available only in <i>/usr/bin/more</i> :
<i>'</i>	Single quote. Go to the point from which the last search started. If no search has been performed in the current file, go to the beginning of the file.
<i>.</i>	Dot. Repeat the previous command.
<i>^ \</i>	Halt a partial display of text. <i>more</i> stops sending output, and displays the usual <i>--More--</i> prompt. Some output is lost as a result.
/usr/xpg4/bin/more	The following commands are available only in <i>/usr/xpg4/bin/more</i> :
<i>i^F</i>	(Control-f) Skip <i>i</i> screens full and print a screenful. (Same as <i>if</i> .)

more(1)

^G	(Control-g) Display the current line number (same as =).
iG	Go to line number <i>i</i> with the default of the first line in the file.
iG	Go to line number <i>i</i> with the default of the Last line in the file.
ij	Display another line, or <i>i</i> more lines, if specified. (Same as <i>i</i> RETURN.)
ik	Scroll backwards one or <i>i</i> lines, if specified.
mletter	Mark the current position with the name <i>letter</i> .
N	Reverse direction of search.
r	Refresh the screen.
R	Refresh the screen, discarding any buffered input.
iü	
i^U	(Control-u) Scroll backwards one half a screen of <i>i</i> lines, if specified. If <i>i</i> is specified, the count becomes the new default for subsequent <i>d</i> and <i>u</i> commands.
ZZ	Exit from more (same as <i>q</i>).
:e file	Examine (display) a new file. If no <i>file</i> is specified, the current file is redisplayed.
:t tagstring	Go to the tag named by the <i>tagstring</i> argument and scroll/rewrite the screen with the tagged line in the current position. See the <i>ctags</i> utility.
' letter	Return to the position that was previously marked with the name <i>letter</i> .
''	Return to the position from which the last move of more than a screenful was made. Defaults to the beginning of the file.
i?[!]pattern	Search backward in the file for the <i>i</i> th line containing the <i>pattern</i> . The <i>!</i> specifies to search backward for the <i>i</i> th line that does not contain the <i>pattern</i> .
i/ !pattern	Search forward in the file for the <i>i</i> th line that does not contain the <i>pattern</i> .
![command]	Invoke a shell or the specified command.

Large File Behavior

See `largefile(5)` for the description of the behavior of more and page when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of more: `LANG`, `LC_ALL`, `LC_COLLATE` (`/usr/xpg4/bin/more` only), `LC_CTYPE`, `LC_MESSAGES`, `NLSPATH`, and `TERM`.

/usr/xpg4/bin/more The following environment variables also affect the execution of `/usr/xpg4/bin/more`:

COLUMNS Overrides the system selected horizontal screen size.

EDITOR Used by the `v` command to select an editor.

LINES Overrides the system selected vertical screen size. The `-n` option has precedence over **LINES** in determining the number of lines in a screen.

MORE A string specifying options as described in the **OPTIONS** section, above. As in a command line, The options must be separated by blank characters and each option specification must start with a `-`. Any command line options are processed after those specified in **MORE** as though the command line were: `more $MORE options operands`

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES `/usr/lib/more.help` help file for `/usr/bin/more` and `/usr/bin/page` only.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

This utility will not behave correctly if the terminal is not set up properly.

NAME	mp – text to PDL (Page Description Language) pretty print filter
SYNOPSIS	<pre>mp [-A4] [-C] [-D target_printer_name] [-F] [-L locale_name] [-P target_spool_printer] [-PS] [-US] [-a] [-c chars] [-d] [-e] [-ff] [-fp] [-l] [-ll] [-m] [-M] [-n] [-o] [-p prologue] [-s subject] [-tm] [-ts] [-u config_file_path] [-v] [-w words] [-z point_size] [-?] [filename...]</pre>
DESCRIPTION	<p>The mp program, when called without the -D or -P option, reads each <i>filename</i> in sequence and generates a prettified version of the contents in PostScript™ format, sent to standard output. If no filename argument is provided, mp reads the standard input. If the standard input is a terminal, input is terminated by an EOF signal, usually Control-d.</p> <p>The -D and -P options require the target printer name as an argument and produce the Page Description Language (PDL) of the target printer. The -D option causes the PDL to output to stdout and the -P option causes the PDL to be directly spooled to the printer. In the absence of these options, mp will product default PostScript™ output.</p> <p>The mp program accepts international text files of various Solaris locales and produces output which is proper for the specified locale. The output will also contain proper text layout. For instance, the output will contain bidirectional text rendering, and also shaping, since the complex text layout (CTL) is supported in mp.</p> <p>Mail items, news articles, ordinary ASCII files, complete mail folders, and digests are all acceptable input formats for mp. The output format includes grayscale lozenges, or the outline of the same dimensions as the lozenges, containing banner information at the top and bottom of every page.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Formats the file as a news article. The top banner contains the text: "Article from <i>newsgroup</i>", where <i>newsgroup</i> is the first news group found on the "Newsgroups:" line. -A4 Uses A4 paper size (8.26 x 11.69 inches). -c <i>chars</i> The maximum number of characters to extract from the <i>gecos</i> field of the user's <i>/etc/passwd</i> entry. The default is 18. -C Instead of using "\nFrom" to denote the start of new mail messages, mp will look for (and use) the value of the Content-Length: mail header. If the Content-Length doesn't take you to the next "\nFrom", then it is wrong, and mp falls back to looking for the next "\nFrom" in the mail folder. -d Formats the file as a digest.

mp(1)

-D <i>target_printer_name</i>	Produces the PDL for the target printer. Requires X Print Server connection.
-e	Assumes the ELM mail frontend intermediate file format. Used when printing messages from within ELM (using the "p" command), especially for printing tagged messages. This option must be specified in your ELM option setup.
-ff	Formats the file for use with a Filofax personal organizer.
-fp	Formats the file for use with a Franklin Planner personal organizer.
-F	Instead of printing who the mail article is <i>for</i> , the top header will contain who the mail article is <i>from</i> . A useful option for people with their own personal printer.
-l	Formats output in landscape mode. Two pages of text will be printed per sheet of paper.
-ll	Formats output in landscape mode. One page of text will be printed per sheet of paper. This is useful for printing files with longer than normal lines.
-L <i>localename</i>	Provides the locale of the file to be printed. If this command line option is not present, then mp looks for the MP_LANG environment variable. If that is not present, then the LANG environment variable is used. If none of these options are present, then mp tries to determine the locale it is running in, and if it cannot, then it assumes it is running in the C locale.
-m	Formats the file as a mail folder, printing multiple messages.
-M	Forces mp to use the mp.conf file for printing output even if a prolog.ps file exists for that locale. Useful when printing to non-native PostScript™ printers.
-n	Turns off the gray bars and associated information from header and footer. Used to get output similar to output of 'lp filename'.
-o	Formats the file as an ordinary ASCII file.
-p <i>prologue</i>	Employs the file <i>prologue</i> as the PostScript/Xprt prologue file, overriding any previously defined file names. This file specifies the format of the print output. For PostScript output, the <i>prologue</i> file will have a .ps extension. For Xprt clients (when the -D option is

	specified), this file will have an <code>.xpr</code> extension. These files are defined in the SUPPLIED PROLOGUE FILES section below.
<code>-P target_spool_printer</code>	Spools the PDL to the target printer. No output is sent to stdout. Requires X Print Server connection.
<code>-PS</code>	If the mail or digest message just has PostScript as the text of the message, this is normally just passed straight through. Specifying this option causes PostScript to be printed as text.
<code>-s subject</code>	Uses <i>subject</i> as the new subject for the printout. If you are printing ordinary ASCII files that have been specified on the command line, the subject will default to the name of each of these files.
<code>-tm</code>	Formats the file for use with the Time Manager personal organizer.
<code>-ts</code>	Formats the file for use with the Time/System International personal organizer.
<code>-US</code>	Uses US paper size (8.5 x 11 inches). This is the default paper size.
<code>-u config_file_path</code>	Specifies an alternate configuration file to the default file <code>/usr/lib/lp/locale/locale_name/mp/mp.conf</code> . The absolute file path name must be used.
<code>-v</code>	Prints the version number of this release of mp.
<code>-w words</code>	The maximum number of words to extract from the <code>gecos</code> field of the user's <code>/etc/passwd</code> entry. The default is 3.
<code>-z point_size</code>	Prints the output text in the point size specified by <i>point_size</i> . The internal default is 12 points for portrait printing and 9 points for landscape printing.
<code>-?</code>	Prints the usage line for mp (notice that the <code>?</code> character must be escaped if using <code>cs(1)</code>).

OPERANDS The following operand is supported:

filename The name of the file to be read.

EXAMPLES The `mp` print filter can be used to print files in any locale which is installed in the user's machine.

mp(1)

EXAMPLE 1 Printing Japanese text files

Japanese text files encoded in the `euC` codeset can be printed in any non-Japanese PostScript™ printers by entering:

```
example% mp -L ja_JP.eucJP -M ja_JP_eucJP.txt | lp
```

Here, the `-L` option specifies the locale and the `-M` option invokes the `mp.conf` configuration file instead of the default `prolog.ps` file. In the case of `ja_JP.eucJP`, both `/usr/lib/lp/locale/ja_JP.eucJP/mp/mp.conf` and `/usr/openwin/lib/locale/ja_JP.eucJP/print/prolog.ps` files are present. Therefore, the `-M` option is used to override the precedence of the default `prolog.ps` file. Using `mp.conf` as the configuration file makes it possible to print to any PostScript printer.

The encoding of the locale specified by the `-L` option and that of the text file to be printed have to be the same. In the above Japanese file example, if the text file is encoded in `Shift-JIS`, use the following command, since the locale `ja_JP.PCK` is encoded in `SJIS`:

```
example% mp -L ja_JP.PCK -M SJIS.txt | lp
```

EXAMPLE 2 Running in `Xprt` mode

If an X Print Server daemon (`/usr/openwin/bin/Xprt`) is running in any system in the network, then `mp` can be invoked as follows, enabling it to output in any Page Description Language supported by `Xprt` (the default value of `display_number` is 2100):

```
example% setenv XPDISPLAY machine_name:display_number
```

To pipe the data to the target printer, enter:

```
example% mp -D printer_name -L ja_JP.eucJP -M ja_JP_eucJP.txt | lp  
-D printer_name
```

For direct spooling when working in `Xprt` client mode, use the `-P` option:

```
example% mp -P printer_name -L ja_JP.eucJP -M ja_JP_eucJP.txt
```

EXAMPLE 3 Turning off the header and footer

Use the `-n` option to turn off the `mp` header and footer:

```
example% mp -n mytext.txt | lp
```

EXAMPLE 4 Printing long text lines

Use the `-ll` option to print text files with longer than 80 column lines in landscape mode:

EXAMPLE 4 Printing long text lines (Continued)

```
example% mp -ll mytext.txt | lp
```

EXAMPLE 5 Specifying print point size

Use the `-z` option to specify any point size, in this case, 20 points:

```
example% mp -z 20 mytext.txt | lp
```

**ENVIRONMENT
VARIABLES**

XPDISPLAY If either the `-D` or `-P` option is specified in the command line and there is no `XPDISPLAY` variable set in the environment, the print server startup script will start an Xprt server at port 2100 in the machine in which the client is running. The script will terminate the print server once the job is over. If `XPDISPLAY` is set, the mp client will try to contact the print server running at `XPDISPLAY`. In this case, no attempt will be made to start the server if it is not running.

MP_PROLOGUE Used to determine the directory where the page formatting files (`.xpr` or `.ps`) are kept. These files determine page decorations, number of logical pages per physical page, landscape or portrait format, and so forth. In the absence of `MP_PROLOGUE`, the default location of the directory is `/usr/lib/lp/locale/C/mp`.

MP_LANG
LANG

If neither of the `-D` or `-P` options is specified, a prologue file is prepended to the output to be printed. The prologue file is called `/usr/openwin/lib/locale/localename/print/prolog.ps` or `/usr/lib/lp/locale/localename/mp/prolog.ps`, where *localename* is the value of the `MP_LANG` or `LANG` environment variable, if present. If both variables are present, the file `/usr/openwin/lib/locale/localename/print/prolog.ps` is given preference due to backward compatibility reasons. If either of these files are not present, and the `-D` option is not specified, a configuration file of the locale called `/usr/lib/lp/locale/localename/mp/mp.conf` is used as the source of the configuration information that substitutes the prologue information for printing. The presence of `prolog.ps` disables `mp.conf` for backward compatibility.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	An error occurred.

mp(1)

**SUPPLIED
PROLOGUE
FILES**

The following prologue files are provided. Files with `.ps` extensions are for the PostScript output. Files with `.xpr` extensions are for the Print Server client. `.xpr` files are created for 300dpi printers and will scale to other resolution values.

<code>mp.common.ps</code>	Common prologue file for all other <code>.ps</code> files in this directory.
<code>mp.pro.ps</code> <code>mp.pro.xpr</code>	Used by default.
<code>mp.pro.ff.ps</code> <code>mp.pro.ff.xpr</code>	Used if the <code>-ff</code> option is in effect.
<code>mp.pro.fp.ps</code> <code>mp.pro.fp.xpr</code>	Used if the <code>-fp</code> option is in effect.
<code>mp.pro.tm.ps</code> <code>mp.pro.tm.xpr</code>	Used if the <code>-tm</code> option is in effect.
<code>mp.pro.ts.ps</code> <code>mp.pro.ts.xpr</code>	Used if the <code>-ts</code> option is in effect.
<code>mp.pro.alt.ps</code> <code>mp.pro.alt.xpr</code>	An alternative modification of the default prologue file which outputs the page number in the right corner of the bottom banner.
<code>mp.pro.l.ps</code> <code>mp.pro.l.xpr</code>	Prologue file used for landscape outputs.
<code>mp.pro.ll.ps</code> <code>mp.pro.ll.xpr</code>	Prologue file used for landscape outputs, when printing files with longer than normal lines.
<code>mp.pro.altl.ps</code> <code>mp.pro.altl.xpr</code>	Alternate prologue file used for landscape outputs.

FILES

<code>.cshrc</code>	Initialization file for <code>csh(1)</code> .
<code>.mailrc</code>	Initialization file for <code>mail(1)</code> .
<code>/usr/bin/mp</code>	Executable.
<code>/usr/lib/lp/locale/C/mp/mp.conf</code>	Default configuration file.
<code>/usr/lib/lp/locale/C/mp/mp.common.ps</code>	Common prologue file for all other <code>.ps</code> files in this directory. Not for <code>.xpr</code> files.
<code>/usr/lib/lp/locale/C/mp/mp.pro.ps</code> <code>/usr/lib/lp/locale/C/mp/mp.pro.xpr</code>	Default prologue files for mail printing.

/usr/lib/lp/locale/C/mp/mp.pro.l.ps

/usr/lib/lp/locale/C/mp/mp.pro.l.xpr

Default prologue files for landscape format.

/usr/lib/lp/locale/C/mp/mp.pro.ll.ps

/usr/lib/lp/locale/C/mp/mp.pro.ll.xpr

Default prologue files for landscape format with one column per page. Useful when printing files with long lines.

/usr/lib/lp/locale/C/mp/mp.pro.altl.ps

/usr/lib/lp/locale/C/mp/mp.pro.altl.xpr

Alternate prologue files for landscape format.

/usr/lib/lp/locale/C/mp/mp.pro.alt.ps

/usr/lib/lp/locale/C/mp/mp.pro.alt.xpr

Alternative "default" prologue files. Insert page numbers in the bottom right corner of each page.

/usr/lib/lp/locale/C/mp/mp.pro.ff.ps

/usr/lib/lp/locale/C/mp/mp.pro.ff.xpr

Default prologue files for Filofax format.

/usr/lib/lp/locale/C/mp/mp.pro.fp.ps

/usr/lib/lp/locale/C/mp/mp.pro.fp.xpr

Default prologue files for Franklin Planner format.

/usr/lib/lp/locale/C/mp/mp.pro.tm.ps

/usr/lib/lp/locale/C/mp/mp.pro.tm.xpr

Default prologue files for Time Manager format.

/usr/lib/lp/locale/C/mp/mp.pro.ts.ps

/usr/lib/lp/locale/C/mp/mp.pro.ts.xpr

Default prologue files for Time/System International format.

/usr/openwin/lib/locale/localename/print/prolog.ps

/usr/lib/lp/locale/localename/mp/prolog.ps

Default locale-specific prologued file as an alternative to the mp.conf file. See ENVIRONMENT VARIABLES for more detail on the relationship.

The structure and format for mp.conf and .xpr files are documented in the *International Language Environments Guide*. Refer to this document if you need to use alternate fonts, including Printer Resident Fonts, or if you want to make changes to output format.

mp(1)

International Language Environments Guide

NAME	mpss.so.1 – shared object for setting preferred page size
SYNOPSIS	mpss.so.1
DESCRIPTION	<p>The <code>mpss.so.1</code> shared object provides a means by which the preferred stack and/or heap page size can be selectively configured for launched processes and their descendants. To enable <code>mpss.so.1</code>, the following string needs to be present in the environment (see <code>ld.so.1(1)</code>) along with one or more MPSS (Multiple Page Size Support) environment variables:</p> <pre>LD_PRELOAD=\$LD_PRELOAD:mpss.so.1</pre>
ENVIRONMENT VARIABLES	<p>Once preloaded, the <code>mpss.so.1</code> shared object reads the following environment variables to determine any preferred page size requirements and any processes these may be specific to.</p> <p><code>MPSSHEAP=size</code> <code>MPSSSTACK=size</code></p> <p><code>MPSSHEAP</code> and <code>MPSSSTACK</code> specify the preferred page sizes for the heap and stack, respectively. The specified page size(s) are applied to all created processes.</p> <p><i>size</i> must be a supported page size (see <code>pagesize(1)</code>) or 0, in which case the system will select an appropriate page size (see <code>memcntl(2)</code>).</p> <p><i>size</i> can be qualified with <code>K</code>, <code>M</code>, <code>G</code>, or <code>T</code> to specify Kilobytes, Megabytes, Gigabytes, or Terabytes respectively.</p> <p><code>MPSSCFGFILE=config-file</code></p> <p><i>config-file</i> is a text file which contains one or more <code>mpss</code> configuration entries of the form:</p> <pre>exec-name exec-args :heap-size :stack-size</pre> <p><i>exec-name</i> specifies the name of an application or executable. The corresponding preferred page size(s) are set for newly created processes (see <code>getexecname(3C)</code>) that match the first <i>exec-name</i> found in the file.</p> <p><i>exec-name</i> can be a full pathname, a base name or a pattern string. See <code>File Name Generation in sh(1)</code> for a discussion of pattern matching.</p> <p><i>exec-args</i> is an optionally specified pattern string to match against arguments. Preferred page size(s) are set only if <i>exec-args</i> is not specified or occurs within the arguments to <i>exec-name</i>.</p> <p>If <i>heap-size</i> and/or <i>stack-size</i> are not specified, the corresponding preferred page size(s) will not be set.</p>

MPSSCFGFILE takes precedence over MPSSHEAP and MPSSSTACK. When MPSSCFGFILE is not set, preferred page size settings are taken from file `/etc/mpss.conf` if it exists.

`MPSSERRFILE=pathname` By default, error messages are logged via `syslog(3C)` using level `LOG_ERR` and facility `LOG_USER`. If `MPSSERRFILE` contains a valid *pathname* (such as `/dev/stderr`), error messages will be logged there instead.

EXAMPLES **EXAMPLE 1** Configuring preferred page sizes using MPSSCFGFILE

The following Bourne shell commands (see `sh(1)`) configure the preferred page sizes to a select set of applications with exec names that begin with `foo`, using the `MPSSCFGFILE` environment variable. The MPSS configuration file, `mpsscfcg`, is assumed to have been previously created via a text editor like `vi(1)`. The `cat(1)` command is only dumping out the contents.

```
example$ LD_PRELOAD=$LD_PRELOAD:mpss.so.1
example$ MPSSCFGFILE=mpsscfcg
example$ export LD_PRELOAD MPSSCFGFILE
example$ cat $MPSSCFGFILE
foo*:512K:64K
```

Once the application has been started, `pmap` (see `proc(1)`) can be used to view the actual page sizes configured:

```
example$ foobar &
example$ pmap -s `pgrep foobar`
```

If the desired page size is not configured (shown in the `pmap` output), it may be due to errors in the MPSS configuration file or environment variables. Check the error log (by default: `/var/adm/messages`) for errors.

If no errors can be found, resource or alignment constraints may be responsible. See the NOTES section.

EXAMPLE 2 Configuring preferred page sizes using MPSSHEAP and MPSSSTACK

The following Bourne shell commands configure 512K heap and 64K stack preferred page sizes for all applications using the `MPSSHEAP` and `MPSSSTACK` environment variables.

```
example$ LD_PRELOAD=$LD_PRELOAD:mpss.so.1
example$ MPSSHEAP=512K
example$ MPSSSTACK=64K
example$ export LD_PRELOAD MPSSHEAP MPSSSTACK
```

EXAMPLE 3 Precedence rules (continuation from Example 2)

The preferred page size configuration in `MPSSCFGFILE` overrides `MPSSHEAP` and `MPSSSTACK`. Appending the following commands to those in Example 2 would mean that all applications will be configured with 512K heap and 64K stack preferred page sizes with the exception of those applications, the `ls` command, and all applications beginning with `ora` that have `ora1` as an argument, in the configuration file.

```
example$ MPSSCFGFILE=mpsscfig2
example$ export MPSSCFGFILE
example$ cat $MPSSCFGFILE
ls::
ora* ora1:4m:4m
```

FILES `/usr/lib/ld/map.bssalign` A template link-editor `mapfile` for aligning bss (see NOTES).
`/etc/mpss.conf` Configuration file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu (32-bit)
	SUNWesxu (64-bit)
Interface Stability	Evolving

SEE ALSO `cat(1)`, `ld(1)`, `ld.so.1(1)`, `pagesize(1)`, `ppgsz(1)`, `proc(1)`, `sh(1)`, `vi(1)`, `exec(2)`, `fork(2)`, `memcntl(2)`, `getexecname(3C)`, `getpagesize(3C)`, `syslog(3C)`, `proc(4)`, `attributes(5)`

NOTES The heap and stack preferred page sizes are inherited. A child process has the same preferred page sizes as its parent. On `exec(2)`, the preferred page sizes are set back to the default system page size unless a preferred page size has been configured via the `mpss` shared object.

`ppgsz(1)`, a `proc` tool, can also be used to set the preferred stack and/or heap page sizes. It cannot selectively configure the page size for descendents based on name matches.

See also NOTES under `ppgsz(1)`.

msgfmt(1)

NAME	msgfmt – create a message object from a message file																						
SYNOPSIS	msgfmt [-D <i>dir</i> --directory= <i>dir</i>] [-f --use-fuzzy] [-g] [-o <i>output-file</i> --output-file= <i>output-file</i>] [-s] [--strict] [-v] [--verbose] <i>filename</i> .po...																						
DESCRIPTION	<p>The msgfmt utility creates message object files from portable object files (<i>filename</i> .po), without changing the portable object files.</p> <p>The .po file contains messages displayed to users by system commands or by application programs. .po files can be edited. The messages in these files can be rewritten in any language supported by the system.</p> <p>The xgettext(1) command can be used to create .po files from script or programs.</p> <p>msgfmt interprets data as characters according to the current setting of the LC_CTYPE locale category or according to the codeset specified in the .po file.</p>																						
OPTIONS	<p>The following options are supported:</p> <table><tr><td>-D <i>dir</i></td><td></td></tr><tr><td>--directory=<i>dir</i></td><td>Adds <i>dir</i> to the list for input files search.</td></tr><tr><td>-f</td><td></td></tr><tr><td>--use-fuzzy</td><td>Uses fuzzy entries in output. If this option is not specified, fuzzy entries are not included into the output. These options are ignored if Solaris message catalogs are processed.</td></tr><tr><td>-g</td><td>Directs the utility to generate the GNU-compatible message catalog file. This option cannot be specified with the -s option.</td></tr><tr><td>-o <i>output-file</i></td><td></td></tr><tr><td>--output=<i>output-file</i></td><td>Specifies the output file name as <i>output-file</i>. All domain directives and duplicate msgids in the .po file are ignored.</td></tr><tr><td>-s</td><td>Directs the utility to generate the Solaris message catalog file. This option cannot be specified with the -g option.</td></tr><tr><td>--strict</td><td>Directs the utility to append the suffix .mo to the generating message object file name if it doesn't have this suffix. This option is ignored if Solaris message catalogs are processed.</td></tr><tr><td>-v</td><td></td></tr><tr><td>--verbose</td><td>Verbose. Lists duplicate message identifiers if Solaris message catalog files are processed. Message strings are not redefined.</td></tr></table>	-D <i>dir</i>		--directory= <i>dir</i>	Adds <i>dir</i> to the list for input files search.	-f		--use-fuzzy	Uses fuzzy entries in output. If this option is not specified, fuzzy entries are not included into the output. These options are ignored if Solaris message catalogs are processed.	-g	Directs the utility to generate the GNU-compatible message catalog file. This option cannot be specified with the -s option.	-o <i>output-file</i>		--output= <i>output-file</i>	Specifies the output file name as <i>output-file</i> . All domain directives and duplicate msgids in the .po file are ignored.	-s	Directs the utility to generate the Solaris message catalog file. This option cannot be specified with the -g option.	--strict	Directs the utility to append the suffix .mo to the generating message object file name if it doesn't have this suffix. This option is ignored if Solaris message catalogs are processed.	-v		--verbose	Verbose. Lists duplicate message identifiers if Solaris message catalog files are processed. Message strings are not redefined.
-D <i>dir</i>																							
--directory= <i>dir</i>	Adds <i>dir</i> to the list for input files search.																						
-f																							
--use-fuzzy	Uses fuzzy entries in output. If this option is not specified, fuzzy entries are not included into the output. These options are ignored if Solaris message catalogs are processed.																						
-g	Directs the utility to generate the GNU-compatible message catalog file. This option cannot be specified with the -s option.																						
-o <i>output-file</i>																							
--output= <i>output-file</i>	Specifies the output file name as <i>output-file</i> . All domain directives and duplicate msgids in the .po file are ignored.																						
-s	Directs the utility to generate the Solaris message catalog file. This option cannot be specified with the -g option.																						
--strict	Directs the utility to append the suffix .mo to the generating message object file name if it doesn't have this suffix. This option is ignored if Solaris message catalogs are processed.																						
-v																							
--verbose	Verbose. Lists duplicate message identifiers if Solaris message catalog files are processed. Message strings are not redefined.																						

If GNU-compatible message files are processed, this option detects and diagnoses input file anomalies which might represent translation errors. The `msgid` and `msgstr` strings are studied and compared. It is considered abnormal if one string starts or ends with a newline while the other does not. Also, if the string represents a format string used in a `printf`-like function, both strings should have the same number of `%` format specifiers, with matching types. If the flag `c-format` appears in the special comment `'#'` for this entry, a check is performed.

USAGE The format of portable object files (`.po` files) is defined as follows. Each `.po` file contains one or more lines, with each line containing either a comment or a statement. Comments start the line with a pound sign (`#`) and end with the newline character. All comments (except special comments described later) and empty lines are ignored. The format of a statement is:

directive value

Each *directive* starts at the beginning of the line and is separated from *value* by white space (such as one or more space or tab characters). *value* consists of one or more quoted strings separated by white space. Use any of the following types of directives for the Solaris message file:

`domain domainname`
`msgid message_identifier`
`msgstr message_string`

For a GNU-compatible message file, use any of the following types of directives:

`domain domainname`
`msgid message_identifier`
`msgid_plural untranslated_string_plural`
`msgstr message_string`
`msgstr[n] message_string`

The behavior of the `domain` directive is affected by the options used. See **OPTIONS** for the behavior when the `-o` or `--output-file` options are specified. If the `-o` or `--output-file` options are not specified, the behavior of the `domain` directive is as follows:

- All `msgid`s from the beginning of each `.po` file to the first `domain` directive are put into a default message object file. The default message object file is named `messages.mo`, if the Solaris message catalog file format is used to generate the message object file or if the `--strict` option is specified. Otherwise, the default message object file is named `messages`.

msgfmt(1)

- When `msgfmt` encounters a `domain` *domainname* directive in the `.po` file, all following `msgid`s until the next `domain` directive are put into the message object file, named `domainname.mo`, if the Solaris message catalog file format is used to generate the message object file or if the `--strict` option is specified. Otherwise, the `msgid`s are put into the message object file named `domainname`.
- Duplicate `msgid`s are defined in the scope of each domain. That is, a `msgid` is considered a duplicate only if the identical `msgid` exists in the same domain.
- All duplicate `msgid`s are ignored.

The `msgid` directive specifies the value of a message identifier associated with the directive that follows it. The `msgid_plural` directive specifies the plural form message specified to the plural message handling functions `ngettext()`, `dngettext()`, or `dcngettext()`. The *message_identifier* string identifies a target string to be used at retrieval time. Each statement containing a `msgid` directive must be followed by a statement containing a `msgstr` directive or `msgstr[n]` directives.

The `msgstr` directive specifies the target string associated with the *message_identifier* string declared in the immediately preceding `msgid` directive.

The directive `msgstr[n]` (where $n = 0, 1, 2, \dots$) specifies the target string to be used with plural form handling functions `ngettext()`, `dngettext()`, and `dcngettext()`.

Message strings can contain the escape sequences `\n` for newline, `\t` for tab, `\v` for vertical tab, `\b` for backspace, `\r` for carriage return, `\f` for formfeed, `\\` for backslash, `\"` for double quote, `\a` for alarm, `\ddd` for octal bit pattern, and `\xDD` for hexadecimal bit pattern.

Comments for a GNU-compatible message file should be in one of the following formats (the `msgfmt` utility will ignore these comments when processing Solaris message files):

```
# translator-comments
# . automatic-comments
# : reference..
# , flag
```

The `'#:'` comments indicate the location of the `msgid` string in the source files in *filename:line* format. The `'#'`, `'#.'`, and `'#:'` comments are informative only and are silently ignored by the `msgfmt` utility. The `'#,'` comments require one or more flags separated by the comma character. The following *flags* can be specified:

<code>fuzzy</code>	This flag can be inserted by the translator. It shows that the <code>msgstr</code> string might not be a correct translation (anymore). Only the translator can judge if the translation requires further modification or is acceptable as is. Once satisfied with the translation, the translator removes this <code>fuzzy</code> flag. If this flag is
--------------------	--

specified, the `msgfmt` utility will not generate the entry for the immediately following `msgid` in the output message catalog.

`c-format`

`no-c-format`

The `c-format` flag indicates that the `msgid` string is used as a format string by `printf`-like functions. In case the `c-format` flag is given for a string, the `msgfmt` utility does some more tests to check the validity of the translation.

In the GNU-compatible message file, the `msgid` entry with empty string ("") is called the header entry and treated specially. If the message string for the header entry contains `nplurals=value`, the value indicates the number of plural forms. For example, if `nplurals=4`, there are four plural forms. If `nplurals` is defined, the same line should contain `plural=expression`, separated by a semicolon character. The *expression* is a C language expression to determine which version of `msgstr[n]` is to be used based on the value of *n*, the last argument of `ngettext()`, `dngettext()`, or `dcngettext()`. For example,

```
nplurals=2; plural= n == 1 ? 0 : 1
```

indicates that there are two plural forms in the language. `msgstr[0]` is used if `n == 1`, otherwise `msgstr[1]` is used. For another example:

```
nplurals=3; plural= n == 1 ? 0 : n == 2 ? 1 : 2
```

indicates that there are three plural forms in the language. `msgstr[0]` is used if `n == 1`, `msgstr[1]` is used if `n == 2`, otherwise `msgstr[2]` is used.

If the header entry contains a `charset=codeset` string, the *codeset* is used to indicate the codeset to be used to encode the message strings. If the output string's codeset is different from the message string's codeset, codeset conversion from the message string's codeset to the output string's codeset will be performed upon the call of `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, and `dcngettext()` for the GNU-compatible message catalogs. The output string's codeset is determined by the current locale's codeset (the return value of `nl_langinfo(CODESET)`) by default, and can be changed by the call of `bind_textdomain_codeset()`.

Message catalog file format

The `msgfmt` utility can generate the message object both in Solaris message catalog file format and in GNU-compatible message catalog file format. If the `-s` option is specified and the input file is a Solaris `.po` file, the `msgfmt` utility generates the message object in Solaris message catalog file format. If the `-g` option is specified and the input file is a GNU `.po` file, the `msgfmt` utility generates the message object in GNU-compatible message catalog file format. If neither the `-s` nor `-g` option is specified, the `msgfmt` utility determines the message catalog file format as follows:

- If the `.po` file contains a valid GNU header entry (having an empty string for `msgid`), the `msgfmt` utility uses the GNU-compatible message catalog file format.
- Otherwise, the `msgfmt` utility uses the Solaris message catalog file format.

msgfmt(1)

If the `msgfmt` utility determined that the Solaris message catalog file format is used, as above, but found the `.po` file contains directives that are specific to the GNU-compatible message catalog file format, such as `msgid_plural` and `msgstr[n]`, the `msgfmt` utility handles those directives as invalid specifications.

EXAMPLES

EXAMPLE 1 Creating message objects from message files

In this example, `module1.po` and `module2.po` are portable message objects files.

```
example% cat module1.po
# default domain "messages.mo"
msgid "msg 1"
msgstr "msg 1 translation"
#
domain "help_domain"
msgid "help 2"
msgstr "help 2 translation"
#
domain "error_domain"
msgid "error 3"
msgstr "error 3 translation"
example% cat module2.po
# default domain "messages.mo"

```

The following command will produce the output files `messages.mo`, `help_domain.mo`, and `error_domain.mo` in Solaris message catalog file format:

```
example% msgfmt module1.po
```

The following command will produce the output files `messages.mo`, `help_domain.mo`, `error_domain.mo`, and `window_domain.mo` in Solaris message catalog file format:

```
example% msgfmt module1.po module2.po
```

The following command will produce the output file `hello.mo` in Solaris message catalog file format:

```
example% msgfmt -o hello.mo module1.po module2.po
```

ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environmental variables that affect the execution of `msgfmt`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc
CSI	Enabled

NOTES Installing message catalogs under the C locale is pointless, since they are ignored for the sake of efficiency.

mt(1)

NAME	mt – magnetic tape control
SYNOPSIS	mt [-f <i>tapename</i>] <i>command</i> ... [<i>count</i>]
DESCRIPTION	The mt utility sends commands to a magnetic tape drive. If -f <i>tapename</i> is not specified, the environment variable TAPE is used. If TAPE does not exist, mt uses the device <code>/dev/rmt/0n</code> .
OPTIONS	The following option is supported: -f <i>tapename</i> Specifies the raw tape device.
OPERANDS	The following operands are supported: <i>count</i> The number of times that the requested operation is to be performed. By default, mt performs <i>command</i> once. Multiple operations of <i>command</i> may be performed by specifying <i>count</i> . <i>command</i> Available commands that can be sent to a magnetic tape drive. Only as many characters as are required to uniquely identify a <i>command</i> need be specified. eof, weof Write <i>count</i> EOF marks at the current position on the tape. fsf Forward space over <i>count</i> EOF marks. The tape is positioned on the first block of the file. fsr Forward space <i>count</i> records. bsf Back space over <i>count</i> EOF marks. The tape is positioned on the beginning-of-tape side of the EOF mark. bsr Back space <i>count</i> records. nbsf Back space <i>count</i> files. The tape is positioned on the first block of the file. This is equivalent to <i>count</i> +1 bsf's followed by one fsf. asf Absolute space to <i>count</i> file number. This is equivalent to a rewind followed by a fsf <i>count</i> . If <i>count</i> is specified with any of the following commands, the <i>count</i> is ignored and the command is performed only once. eom Space to the end of recorded media on the tape. This is useful for appending files onto previously written tapes. rewind Rewind the tape.

offline, rewoffl	Rewind the tape and, if appropriate, take the drive unit off-line by unloading the tape. It cycles through all four tapes.
status	Print status information about the tape unit.
retension	Rewind the cartridge tape completely, then wind it forward to the end of the reel and back to beginning-of-tape to smooth out tape tension.
reserve	Allow the tape drive to remain reserved after closing the device. The drive must then be explicitly released.
release	Re-establish the default behavior of releasing at close.
forcereserve	Break the reservation of the tape drive held by another host and then reserve the tape drive. This command can be executed only with super-user privileges.
erase	Erase the entire tape. Erasing a tape may take a long time depending on the device and/or tape. Refer to the device specific manual for time details.

EXIT STATUS	0	All operations were successful.
	1	Command was unrecognized or mt was unable to open the specified tape drive.
	2	An operation failed.

FILES /dev/rmt/* magnetic tape interface

mt(1)

BUGS | Not all devices support all options. Some options are hardware-dependent. Refer to the corresponding device manual page.

mt is architecture sensitive. Heterogeneous operation (that is, SPARC to IA or the reverse) is not supported.

NAME	mv – move files
SYNOPSIS	<pre> /usr/bin/mv [-fi] source target_file /usr/bin/mv [-fi] source... target_dir /usr/xpg4/bin/mv [-fi] source target_file /usr/xpg4/bin/mv [-fi] source... target_dir </pre>
DESCRIPTION	<p>In the first synopsis form, the mv utility moves the file named by the <i>source</i> operand to the destination specified by the <i>target_file</i>. <i>source</i> and <i>target_file</i> may not have the same name. If <i>target_file</i> does not exist, mv creates a file named <i>target_file</i>. If <i>target_file</i> exists, its contents are overwritten. This first synopsis form is assumed when the final operand does not name an existing directory.</p> <p>In the second synopsis form, mv moves each file named by a <i>source</i> operand to a destination file in the existing directory named by the <i>target_dir</i> operand. The destination path for each <i>source</i> is the concatenation of the target directory, a single slash character (/), and the last path name component of the <i>source</i>. This second form is assumed when the final operand names an existing directory.</p> <p>If mv determines that the mode of <i>target_file</i> forbids writing, it will print the mode (see <code>chmod(2)</code>), ask for a response, and read the standard input for one line. If the response is affirmative, the mv occurs, if permissible; otherwise, the command exits. Notice that the mode displayed may not fully represent the access permission if <i>target</i> is associated with an ACL. When the parent directory of <i>source</i> is writable and has the sticky bit set, one or more of the following conditions must be true:</p> <ul style="list-style-type: none"> ■ the user must own the file ■ the user must own the directory ■ the file must be writable by the user ■ the user must be a privileged user <p>If <i>source</i> is a file and <i>target_file</i> is a link to another file with links, the other links remain and <i>target_file</i> becomes a new file.</p> <p>If <i>source</i> and <i>target_file/target_dir</i> are on different file systems, mv copies the source and deletes the original. Any hard links to other files are lost. mv will attempt to duplicate the source file characteristics to the target, that is, the owner and group id, permission modes, modification and access times, ACLs, and extended attributes, if applicable. For symbolic links, mv will preserve only the owner and group of the link itself.</p> <p>If unable to preserve owner and group id, mv will clear <code>S_ISUID</code> and <code>S_ISGID</code> bits in the target. mv will print a diagnostic message to stderr if unable to clear these bits, though the exit code will not be affected. mv may be unable to preserve extended attributes if the target file system does not have extended attribute support. <code>/usr/xpg4/bin/mv</code> will print a diagnostic message to stderr for all other failed attempts to duplicate file characteristics. The exit code will not be affected.</p>

mv(1)

In order to preserve the source file characteristics, users must have the appropriate file access permissions. This includes being super-user or having the same owner id as the destination file.

OPTIONS The following options are supported:

- f mv will move the file(s) without prompting even if it is writing over an existing *target*. Note that this is the default if the standard input is not a terminal.
- i mv will prompt for confirmation whenever the move would overwrite an existing *target*. An affirmative answer means that the move should proceed. Any other answer prevents mv from overwriting the *target*.

/usr/bin/mv Specifying both the -f and the -i options is not considered an error. The -f option will override the -i option.

/usr/xpg4/bin/mv Specifying both the -f and the -i options is not considered an error. The last option specified will determine the behavior of mv.

OPERANDS The following operands are supported:

- source* A path name of a file or directory to be moved.
- target_file* A new path name for the file or directory being moved.
- target_dir* A path name of an existing directory into which to move the input files.

USAGE See *largefile(5)* for the description of the behavior of mv when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES See *environ(5)* for descriptions of the following environment variables that affect the execution of mv: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLS_PATH.

EXIT STATUS The following exit values are returned:

- 0 All input files were moved successfully.
- >0 An error occurred.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

/usr/bin/mv

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

`/usr/xpg4/bin/mv`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled
Interface Stability	Standard

SEE ALSO `cp(1)`, `cpio(1)`, `ln(1)`, `rm(1)`, `setfacl(1)`, `chmod(2)`, `attributes(5)`, `environ(5)`, `fsattr(5)`, `largefile(5)`, `standards(5)`

NOTES A `--` permits the user to mark explicitly the end of any command line options, allowing `mv` to recognize filename arguments that begin with a `-`. As an aid to BSD migration, `mv` will accept `-` as a synonym for `--`. This migration aid may disappear in a future release.

nawk(1)

NAME	nawk – pattern scanning and processing language
SYNOPSIS	<pre> /usr/bin/nawk [-F ERE] [-v assignment] 'program' -f progfile... [argument...] /usr/xpg4/bin/awk [-F ERE] [-v assignment...] 'program' -f progfile... [argument...] </pre>
DESCRIPTION	<p>The <code>/usr/bin/nawk</code> and <code>/usr/xpg4/bin/awk</code> utilities execute <i>programs</i> written in the <code>nawk</code> programming language, which is specialized for textual data manipulation. A <code>nawk program</code> is a sequence of patterns and corresponding actions. The string specifying <i>program</i> must be enclosed in single quotes (') to protect it from interpretation by the shell. The sequence of pattern - action statements can be specified in the command line as <i>program</i> or in one, or more, file(s) specified by the <code>-f progfile</code> option. When input is read that matches a pattern, the action associated with the pattern is performed.</p> <p>Input is interpreted as a sequence of records. By default, a record is a line, but this can be changed by using the <code>RS</code> built-in variable. Each record of input is matched to each pattern in the <i>program</i>. For each pattern matched, the associated action is executed.</p> <p>The <code>nawk</code> utility interprets each input record as a sequence of fields where, by default, a field is a string of non-blank characters. This default white-space field delimiter (blanks and/or tabs) can be changed by using the <code>FS</code> built-in variable or the <code>-F ERE</code> option. The <code>nawk</code> utility denotes the first field in a record <code>\$1</code>, the second <code>\$2</code>, and so forth. The symbol <code>\$0</code> refers to the entire record; setting any other field causes the reevaluation of <code>\$0</code>. Assigning to <code>\$0</code> resets the values of all fields and the <code>NF</code> built-in variable.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-F ERE</code> Define the input field separator to be the extended regular expression <i>ERE</i>, before any input is read (can be a character). <code>-f progfile</code> Specifies the pathname of the file <i>progfile</i> containing a <code>nawk</code> program. If multiple instances of this option are specified, the concatenation of the files specified as <i>progfile</i> in the order specified is the <code>nawk</code> program. The <code>nawk</code> program can alternatively be specified in the command line as a single argument. <code>-v assignment</code> The <i>assignment</i> argument must be in the same form as an <i>assignment</i> operand. The assignment is of the form <i>var=value</i>, where <i>var</i> is the name of one of the variables described below. The specified assignment occurs before executing the <code>nawk</code> program, including the actions associated with <code>BEGIN</code> patterns (if any). Multiple occurrences of this option can be specified.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"> <i>program</i> If no <code>-f</code> option is specified, the first operand to <code>nawk</code> is the text of the <code>nawk</code> program. The application supplies the <i>program</i> operand

as a single argument to `nawk`. If the text does not end in a newline character, `nawk` interprets the text as if it did.

argument

Either of the following two types of *argument* can be intermixed:

file

A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no *file* operands are specified, or if a *file* operand is `-`, the standard input is used.

assignment

An operand that begins with an underscore or alphabetic character from the portable character set, followed by a sequence of underscores, digits and alphabetic characters from the portable character set, followed by the `=` character specifies a variable assignment rather than a pathname. The characters before the `=` represent the name of a `nawk` variable; if that name is a `nawk` reserved word the behavior is undefined. The characters following the equal sign is interpreted as if they appeared in the `nawk` program preceded and followed by a double-quote (`"`) character, as a `STRING` token, except that if the last character is an unescaped backslash, it is interpreted as a literal backslash rather than as the first character of the sequence `"\"`. The variable is assigned the value of that `STRING` token. If the value is considered a *numericstring*, the variable is assigned its numeric value. Each such variable assignment is performed just before the processing of the following *file*, if any. Thus, an assignment before the first *file* argument is executed after the `BEGIN` actions (if any), while an assignment after the last *file* argument is executed before the `END` actions (if any). If there are no *file* arguments, assignments are executed before processing the standard input.

INPUT FILES

Input files to the `nawk` program from any of the following sources:

- any *file* operands or their equivalents, achieved by modifying the `nawk` variables `ARGV` and `ARGC`
- standard input in the absence of any *file* operands
- arguments to the `getline` function

nawk(1)

**EXTENDED
DESCRIPTION**

must be text files. Whether the variable `RS` is set to a value other than a newline character or not, for these files, implementations support records terminated with the specified separator up to `{LINE_MAX}` bytes and may support longer records.

If `-f progfile` is specified, the files named by each of the `progfile` option-arguments must be text files containing an `nawk` program.

The standard input are used only if no `file` operands are specified, or if a `file` operand is `-`.

A `nawk` program is composed of pairs of the form:

```
pattern { action }
```

Either the pattern or the action (including the enclosing brace characters) can be omitted. Pattern-action statements are separated by a semicolon or by a newline.

A missing pattern matches any record of input, and a missing action is equivalent to an action that writes the matched record of input to standard output.

Execution of the `nawk` program starts by first executing the actions associated with all `BEGIN` patterns in the order they occur in the program. Then each `file` operand (or standard input if no files were specified) is processed by reading data from the file until a record separator is seen (a newline character by default), splitting the current record into fields using the current value of `FS`, evaluating each pattern in the program in the order of occurrence, and executing the action associated with each pattern that matches the current record. The action for a matching pattern is executed before evaluating subsequent patterns. Last, the actions associated with all `END` patterns is executed in the order they occur in the program.

**Expressions in
nawk**

Expressions describe computations used in *patterns* and *actions*. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators are evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent any expression, while *lvalue* represents any entity that can be assigned to (that is, on the left side of an assignment operator).

Syntax	Name	Type of Result	Associativity
<code>(expr)</code>	Grouping	type of <i>expr</i>	n/a
<code>\$expr</code>	Field reference	string	n/a
<code>++ lvalue</code>	Pre-increment	numeric	n/a
<code>-- lvalue</code>	Pre-decrement	numeric	n/a
<code>lvalue ++</code>	Post-increment	numeric	n/a

Syntax	Name	Type of Result	Associativity
<i>lvalue</i> —	Post-decrement	numeric	n/a
<i>expr</i> ^ <i>expr</i>	Exponentiation	numeric	right
! <i>expr</i>	Logical not	numeric	n/a
+ <i>expr</i>	Unary plus	numeric	n/a
– <i>expr</i>	Unary minus	numeric	n/a
<i>expr</i> * <i>expr</i>	Multiplication	numeric	left
<i>expr</i> / <i>expr</i>	Division	numeric	left
<i>expr</i> % <i>expr</i>	Modulus	numeric	left
<i>expr</i> + <i>expr</i>	Addition	numeric	left
<i>expr</i> – <i>expr</i>	Subtraction	numeric	left
<i>expr</i> <i>expr</i>	String concatenation	string	left
<i>expr</i> < <i>expr</i>	Less than	numeric	none
<i>expr</i> <= <i>expr</i>	Less than or equal to	numeric	none
<i>expr</i> != <i>expr</i>	Not equal to	numeric	none
<i>expr</i> == <i>expr</i>	Equal to	numeric	none
<i>expr</i> > <i>expr</i>	Greater than	numeric	none
<i>expr</i> >= <i>expr</i>	Greater than or equal to	numeric	none
<i>expr</i> ~ <i>expr</i>	ERE match	numeric	none
<i>expr</i> !~ <i>expr</i>	ERE non-match	numeric	none
<i>expr</i> in <i>array</i>	Array membership	numeric	left
(<i>index</i>) in <i>array</i>	Multi-dimension array membership	numeric	left
<i>expr</i> && <i>expr</i>	Logical AND	numeric	left
<i>expr</i> <i>expr</i>	Logical OR	numeric	left
<i>expr1</i> ? <i>expr2</i> : <i>expr3</i>	Conditional expression	type of selected <i>expr2</i> or <i>expr3</i>	right
<i>lvalue</i> ^= <i>expr</i>	Exponentiation	numeric	right

nawk(1)

Syntax	Name	Type of Result	Associativity
	assignment		
<i>lvalue</i> %= <i>expr</i>	Modulus assignment	numeric	right
<i>lvalue</i> *= <i>expr</i>	Multiplication	numeric	right
	assignment		
<i>lvalue</i> /= <i>expr</i>	Division assignment	numeric	right
<i>lvalue</i> += <i>expr</i>	Addition assignment	numeric	right
<i>lvalue</i> -= <i>expr</i>	Subtraction assignment	numeric	right
<i>lvalue</i> = <i>expr</i>	Assignment	type of <i>expr</i>	right

Each expression has either a string value, a numeric value or both. Except as stated for specific contexts, the value of an expression is implicitly converted to the type needed for the context in which it is used. A string value is converted to a numeric value by the equivalent of the following calls:

```
setlocale(LC_NUMERIC, "");  
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer is converted to a string by the equivalent of a call to the `sprintf` function with the string `%d` as the `fmt` argument and the numeric value being converted as the first and only *expr* argument. Any other numeric value is converted to a string by the equivalent of a call to the `sprintf` function with the value of the variable `CONVFMT` as the `fmt` argument and the numeric value being converted as the first and only *expr* argument.

A string value is considered to be a *numeric string* in the following case:

1. Any leading and trailing blank characters is ignored.
2. If the first unignored character is a + or -, it is ignored.
3. If the remaining unignored characters would be lexically recognized as a `NUMBER` token, the string is considered a *numeric string*.

If a - character is ignored in the above steps, the numeric value of the *numeric string* is the negation of the numeric value of the recognized `NUMBER` token. Otherwise the numeric value of the *numeric string* is the numeric value of the recognized `NUMBER` token. Whether or not a string is a *numeric string* is relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero is treated as false and any other value is treated as true. Otherwise, a string value of the null string is treated as false and any other value is treated as true. A Boolean context is one of the following:

- the first subexpression of a conditional expression.
- an expression operated on by logical NOT, logical AND, or logical OR.
- the second expression of a `for` statement.
- the expression of an `if` statement.
- the expression of the `while` clause in either a `while` or `do . . . while` statement.
- an expression used as a pattern (as in Overall Program Structure).

The `nawk` language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They are initially empty, and their sizes changes dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an *lvalue* and as an expression, as described in the grammar. Unsubscripted array names are used in only the following contexts:

- a parameter in a function definition or function call.
- the `NAME` token following any use of the keyword `in`.

A valid array *index* consists of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because `nawk` arrays are really one-dimensional, such a comma-separated list is converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the `SUBSEP` variable.

Thus, the following two index operations are equivalent:

```
var[expr1, expr2, ... exprn]
var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]
```

A multi-dimensioned *index* used with the `in` operator must be put in parentheses. The `in` operator, which tests for the existence of a particular array element, does not create the element if it does not exist. Any other reference to a non-existent array element automatically creates it.

Variables and Special Variables

Variables can be used in an `nawk` program by referencing them. With the exception of function parameters, they are not explicitly declared. Uninitialized scalar variables and array elements have both a numeric value of zero and a string value of the empty string.

Field variables are designated by a `$` followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables are created by assigning a value to them. References to non-existent fields (that is, fields after `$NF`) produce the null string. However, assigning to a non-existent field (for example, `$(NF+2) = 5`) increases the value of `NF`, create any intervening fields with the null string as their values and cause the value of `$0` to be recomputed, with the fields being separated by the value of `OFS`. Each field variable has a string value when created. If

nawk(1)

the string, with any occurrence of the decimal-point character from the current locale changed to a period character, is considered a *numeric string* (see Expressions in nawk above), the field variable also has the numeric value of the *numeric string*.

nawk sets the following special variables:

ARGC The number of elements in the ARGV array.

ARGV An array of command line arguments, excluding options and the *program* argument, numbered from zero to ARGC-1.

The arguments in ARGV can be modified or added to; ARGC can be altered. As each input file ends, nawk treats the next non-null element of ARGV, up to the current value of ARGC-1, inclusive, as the name of the next input file. Setting an element of ARGV to null means that it is not treated as an input file. The name - indicates the standard input. If an argument matches the format of an *assignment* operand, this argument is treated as an assignment rather than a *file* argument.

/usr/xpg4/bin/awk

CONVFMT The printf format for converting numbers to strings (except for output statements, where OFMT is used); % . 6g by default.

ENVIRON The variable ENVIRON is an array representing the value of the environment. The indices of the array are strings consisting of the names of the environment variables, and the value of each array element is a string consisting of the value of that variable. If the value of an environment variable is considered a *numeric string*, the array element also has its numeric value.

In all cases where nawk behavior is affected by environment variables (including the environment of any commands that nawk executes via the system function or via pipeline redirections with the print statement, the printf statement, or the getline function), the environment used is the environment at the time nawk began executing.

FILENAME A pathname of the current input file. Inside a BEGIN action the value is undefined. Inside an END action the value is the name of the last input file processed.

FNR The ordinal number of the current record in the current file. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed in the last file processed.

FS Input field separator regular expression; a space character by default.

NF The number of fields in the current record. Inside a BEGIN action, the use of NF is undefined unless a getline function without a var argument is executed previously. Inside an END action, NF retains the value it had for the last record read, unless a

	subsequent, redirected, <code>getline</code> function without a <code>var</code> argument is performed prior to entering the <code>END</code> action.
NR	The ordinal number of the current record from the start of input. Inside a <code>BEGIN</code> action the value is zero. Inside an <code>END</code> action the value is the number of the last record processed.
OFMT	The <code>printf</code> format for converting numbers to strings in output statements <code>"%.6g"</code> by default. The result of the conversion is unspecified if the value of <code>OFMT</code> is not a floating-point format specification.
OFS	The <code>print</code> statement output field separator; a space character by default.
ORS	The <code>print</code> output record separator; a newline character by default.
LENGTH	The length of the string matched by the <code>match</code> function.
RS	The first character of the string value of <code>RS</code> is the input record separator; a newline character by default. If <code>RS</code> contains more than one character, the results are unspecified. If <code>RS</code> is null, then records are separated by sequences of one or more blank lines: leading or trailing blank lines do not produce empty records at the beginning or end of input, and the field separator is always newline, no matter what the value of <code>FS</code> .
RSTART	The starting position of the string matched by the <code>match</code> function, numbering from 1. This is always equivalent to the return value of the <code>match</code> function.
SUBSEP	The subscript separator string for multi-dimensional arrays; the default value is 1

Regular Expressions

The `nawk` utility makes use of the extended regular expression notation (see `regex(5)`) except that it allows the use of C-language conventions to escape special characters within the EREs, namely `\\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, and those specified in the following table. These escape sequences are recognized both inside and outside bracket expressions. Note that records need not be separated by newline characters and string constants can contain newline characters, so even the `\n` sequence is valid in `nawk` EREs. Using a slash character within the regular expression requires escaping as shown in the table below:

Escape Sequence	Description	Meaning
<code>\"</code>	Backslash quotation-mark	Quotation-mark character
<code>\/</code>	Backslash slash	Slash character

nawk(1)

<code>\ddd</code>	A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NULL character), the behavior is undefined.	The character encoded by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences, including the leading <code>\</code> for each byte.
<code>\c</code>	A backslash character followed by any character not described in this table or special characters (<code>\\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code>).	Undefined

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, `~` and `! ~`. These operators interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the `~` expression evaluates to the value 1, and the `! ~` expression evaluates to the value 0. If the regular expression does not match the string, the `~` expression evaluates to the value 0, and the `! ~` expression evaluates to the value 1. If the right-hand operand is any expression other than the lexical token `ERE`, the string value of the expression is interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions also are applied in the determining the value of a string literal (the lexical token `STRING`), and is applied a second time when a string literal is used in this context.

When an `ERE` token appears as an expression in any context other than as the right-hand of the `~` or `! ~` operator or as one of the built-in function arguments described below, the value of the resulting expression is the equivalent of:

```
$0 ~ /ere/
```

The `ere` argument to the `gsub`, `match`, `sub` functions, and the `fs` argument to the `split` function (see `String Functions`) is interpreted as extended regular expressions. These can be either `ERE` tokens or arbitrary expressions, and are interpreted in the same manner as the right-hand side of the `~` or `! ~` operator.

An extended regular expression can be used to separate fields by using the `-F ERE` option or by assigning a string containing the expression to the built-in variable `FS`. The default value of the `FS` variable is a single space character. The following describes `FS` behavior:

1. If `FS` is a single character:
 - If `FS` is the space character, skip leading and trailing blank characters; fields are delimited by sets of one or more blank characters.
 - Otherwise, if `FS` is any other character `c`, fields are delimited by each single occurrence of `c`.

2. Otherwise, the string value of `FS` is considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression delimits fields.

Except in the `gsub`, `match`, `split`, and `sub` built-in functions, regular expression matching is based on input records; that is, record separator characters (the first character of the value of the variable `RS`, a newline character by default) cannot be embedded in the expression, and no expression matches the record separator character. If the record separator is not a newline character, newline characters embedded in the expression can be matched. In those four built-in functions, regular expression matching are based on text strings. So, any character (including the newline character and the record separator) can be embedded in the pattern and an appropriate pattern will match any character. However, in all `nawk` regular expression matching, the use of one or more NUL characters in the pattern, input record or text string produces undefined results.

Patterns	<i>A pattern</i> is any valid <i>expression</i> , a range specified by two expressions separated by comma, or one of the two special patterns <code>BEGIN</code> or <code>END</code> .
Special Patterns	The <code>nawk</code> utility recognizes two special patterns, <code>BEGIN</code> and <code>END</code> . Each <code>BEGIN</code> pattern is matched once and its associated action executed before the first record of input is read (except possibly by use of the <code>getline</code> function in a prior <code>BEGIN</code> action) and before command line assignment is done. Each <code>END</code> pattern is matched once and its associated action executed after the last record of input has been read. These two patterns have associated actions. <code>BEGIN</code> and <code>END</code> do not combine with other patterns. Multiple <code>BEGIN</code> and <code>END</code> patterns are allowed. The actions associated with the <code>BEGIN</code> patterns are executed in the order specified in the program, as are the <code>END</code> actions. An <code>END</code> pattern can precede a <code>BEGIN</code> pattern in a program. If an <code>nawk</code> program consists of only actions with the pattern <code>BEGIN</code> , and the <code>BEGIN</code> action contains no <code>getline</code> function, <code>nawk</code> exits without reading its input when the last statement in the last <code>BEGIN</code> action is executed. If an <code>nawk</code> program consists of only actions with the pattern <code>END</code> or only actions with the patterns <code>BEGIN</code> and <code>END</code> , the input is read before the statements in the <code>END</code> actions are executed.
Expression Patterns	An expression pattern is evaluated as if it were an expression in a Boolean context. If the result is true, the pattern is considered to match, and the associated action (if any) is executed. If the result is false, the action is not executed.
Pattern Ranges	A pattern range consists of two expressions separated by a comma. In this case, the action is performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.
Actions	An action is a sequence of statements. A statement may be one of the following: <pre>if (expression) statement [else statement] while (expression) statement</pre>

nawk(1)

```
do statement while ( expression )
for ( expression ; expression ; expression ) statement
for ( var in array ) statement
delete array[subscript] #delete an array element
break
continue
{ [ statement ] . . . }
expression          # commonly variable = expression
print [ expression-list ] [ >expression ]
printf format [ ,expression-list ] [ >expression ]
next                # skip remaining patterns on this input line
exit [expr] # skip the rest of the input; exit status is expr
return [expr]
```

Any single statement can be replaced by a statement list enclosed in braces. The statements are terminated by newline characters or semicolons, and are executed sequentially in the order that they appear.

The `next` statement causes all further processing of the current input record to be abandoned. The behavior is undefined if a `next` statement appears or is invoked in a `BEGIN` or `END` action.

The `exit` statement invokes all `END` actions in the order in which they occur in the program source and then terminate the program without reading further input. An `exit` statement inside an `END` action terminates the program without further execution of `END` actions. If an expression is specified in an `exit` statement, its numeric value is the exit status of `nawk`, unless subsequent errors are encountered or a subsequent `exit` statement with an expression is executed.

Output Statements

Both `print` and `printf` statements write to standard output by default. The output is written to the location specified by *output_redirection* if one is supplied, as follows:

```
> expression>> expression | expression
```

In all cases, the *expression* is evaluated to produce a string that is used as a full pathname to write into (for `>` or `>>`) or as a command to be executed (for `|`). Using the first two forms, if the file of that name is not currently open, it is opened, creating it if necessary and using the first form, truncating the file. The output then is appended to the file. As long as the file remains open, subsequent calls in which *expression* evaluates to the same string value simply appends output to the file. The file remains open until the `close` function, which is called with an expression that evaluates to the same string value.

The third form writes output onto a stream piped to the input of a command. The stream is created if no stream is currently open with the value of *expression* as its command name. The stream created is equivalent to one created by a call to the `popen(3C)` function with the value of *expression* as the *command* argument and a value of `w` as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value writes output to the existing stream. The stream will remain open until the `close` function is called with an expression that evaluates to the same string value. At that time, the stream is closed as if by a call to the `pclose` function.

These output statements take a comma-separated list of *expression s* referred in the grammar by the non-terminal symbols `expr_list`, `print_expr_list` or `print_expr_list_opt`. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The `print` statement writes the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable `OFS` above), and terminated by the output record separator (see variable `ORS` above). All expression arguments is taken as strings, being converted if necessary; with the exception that the `printf` format in `OFMT` is used instead of the value in `CONVFMT`. An empty expression list stands for the whole input record (`$0`).

The `printf` statement produces output based on a notation similar to the File Format Notation used to describe file formats in this document. Output is produced as specified with the first expression argument as the string *format* and subsequent expression arguments as the strings *arg1* to *argn*, inclusive, with the following exceptions:

1. The *format* is an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The space character in the *format* string, in any context other than a *flag* of a conversion specification, is treated as an ordinary character that is copied to the output.
2. If the character set contains a Delta character and that character appears in the *format* string, it is treated as an ordinary character that is copied to the output.
3. The *escape sequences* beginning with a backslash character is treated as sequences of ordinary characters that are copied to the output. Note that these same sequences is interpreted lexically by `nawk` when they appear in literal strings, but they is not treated specially by the `printf` statement.
4. A *field width* or *precision* can be specified as the `*` character instead of a digit string. In this case the next argument from the expression list is fetched and its numeric value taken as the field width or precision.
5. The implementation does not precede or follow output from the `d` or `u` conversion specifications with blank characters not specified by the *format* string.
6. The implementation does not precede output from the `o` conversion specification with leading zeros not specified by the *format* string.
7. For the `c` conversion specification: if the argument has a numeric value, the character whose encoding is that value is output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value will be output; if the string does not contain any characters the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument will be evaluated. With the exception of the `c` conversion, the value will be converted to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.

nawk(1)

10. If any character sequence in the *format* string begins with a % character, but does not form a valid conversion specification, the behavior is unspecified.

Both `print` and `printf` can output at least `{LINE_MAX}` bytes.

Functions The nawk language has a variety of built-in functions: arithmetic, string, input/output and general.

Arithmetic Functions The arithmetic functions, except for `int`, are based on the ISO C standard. The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `[]` brackets), such use is undefined.

`atan2(y,x)` Return arctangent of y/x .

`cos(x)` Return cosine of x , where x is in radians.

`sin(x)` Return sine of x , where x is in radians.

`exp(x)` Return the exponential function of x .

`log(x)` Return the natural logarithm of x .

`sqrt(x)` Return the square root of x .

`int(x)` Truncate its argument to an integer. It will be truncated toward 0 when $x > 0$.

`rand()` Return a random number n , such that $0 \leq n < 1$.

`srand([expr])` Set the seed value for `rand` to *expr* or use the time of day if *expr* is omitted. The previous seed value will be returned.

String Functions The string functions in the following list shall be supported. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `[]` brackets), such use is undefined.

`gsub(ere,repl[,in])` Behave like `sub` (see below), except that it will replace all occurrences of the regular expression (like the `ed` utility global substitute) in `$0` or in the *in* argument, when specified.

`index(s,t)` Return the position, in characters, numbering from 1, in string *s* where string *t* first occurs, or zero if it does not occur at all.

`length([s])` Return the length, in characters, of its argument taken as a string, or of the whole record, `$0`, if there is no argument.

match(<i>s,ere</i>)	Return the position, in characters, numbering from 1, in string <i>s</i> where the extended regular expression <i>ere</i> occurs, or zero if it does not occur at all. RSTART will be set to the starting position (which is the same as the returned value), zero if no match is found; RLENGTH will be set to the length of the matched string, -1 if no match is found.
split(<i>s,a[,fs]</i>)	Split the string <i>s</i> into array elements <i>a</i> [1], <i>a</i> [2], . . . , <i>a</i> [<i>n</i>], and return <i>n</i> . The separation will be done with the extended regular expression <i>fs</i> or with the field separator FS if <i>fs</i> is not given. Each array element will have a string value when created. If the string assigned to any array element, with any occurrence of the decimal-point character from the current locale changed to a period character, would be considered a <i>numeric string</i> ; the array element will also have the numeric value of the <i>numeric string</i> . The effect of a null string as the value of <i>fs</i> is unspecified.
sprintf(<i>fmt,expr,expr,...</i>)	Format the expressions according to the printf format given by <i>fmt</i> and return the resulting string.
sub(<i>ere,repl[,in]</i>)	Substitute the string <i>repl</i> in place of the first instance of the extended regular expression <i>ERE</i> in string <i>in</i> and return the number of substitutions. An ampersand (&) appearing in the string <i>repl</i> will be replaced by the string from <i>in</i> that matches the regular expression. For each occurrence of backslash (\) encountered when scanning the string <i>repl</i> from beginning to end, the next character is taken literally and loses its special meaning (for example, \& will be interpreted as a literal ampersand character). Except for & and \, it is unspecified what the special meaning of any such character is. If <i>in</i> is specified and it is not an <i>lvalue</i> the behavior is undefined. If <i>in</i> is omitted, nawk will substitute in the current record (\$0) .

nawk(1)

<code>substr(s,m[, n])</code>	Return the at most <i>n</i> -character substring of <i>s</i> that begins at position <i>m</i> , numbering from 1. If <i>n</i> is missing, the length of the substring will be limited by the length of the string <i>s</i> .
<code>tolower(s)</code>	Return a string based on the string <i>s</i> . Each character in <i>s</i> that is an upper-case letter specified to have a <code>tolower</code> mapping by the <code>LC_CTYPE</code> category of the current locale will be replaced in the returned string by the lower-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string.
<code>toupper(s)</code>	Return a string based on the string <i>s</i> . Each character in <i>s</i> that is a lower-case letter specified to have a <code>toupper</code> mapping by the <code>LC_CTYPE</code> category of the current locale will be replaced in the returned string by the upper-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string.

All of the preceding functions that take *ERE* as a parameter expect a pattern or a string valued expression that is a regular expression as defined below.

Input/Output and General Functions

The input/output and general functions are:

<code>close (expression)</code>	Close the file or pipe opened by a <code>print</code> or <code>printf</code> statement or a call to <code>getline</code> with the same string-valued <i>expression</i> . If the close was successful, the function will return 0; otherwise, it will return non-zero.
<code>expression getline[var]</code>	Read a record of input from a stream piped from the output of a command. The stream will be created if no stream is currently open with the value of <i>expression</i> as its command name. The stream created will be equivalent to one created by a call to the <code>popen</code> function with the value of <i>expression</i> as the <i>command</i> argument and a value of <code>r</code> as the <i>mode</i> argument. As long as the stream remains open, subsequent calls in which <i>expression</i> evaluates to the same string value will read subsequent records from the file. The stream will remain open until the <code>close</code> function is called with an expression that evaluates to the same string value. At

that time, the stream will be closed as if by a call to the `pclose` function. If *var* is missing, `$0` and `NF` will be set; otherwise, *var* will be set.

The `getline` operator can form ambiguous constructs when there are operators that are not in parentheses (including concatenate) to the left of the `|` (to the beginning of the expression containing `getline`). In the context of the `$` operator, `|` behaves as if it had a lower precedence than `$`. The result of evaluating other operators is unspecified, and all such uses of portable applications must be put in parentheses properly.

`getline`

Set `$0` to the next input record from the current input file. This form of `getline` will set the `NF`, `NR`, and `FNR` variables.

`getline var`

Set variable *var* to the next input record from the current input file. This form of `getline` will set the `FNR` and `NR` variables.

`getline [var] < expression`

Read the next record of input from a named file. The *expression* will be evaluated to produce a string that is used as a full pathname. If the file of that name is not currently open, it will be opened. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value will read subsequent records from the file. The file will remain open until the `close` function is called with an expression that evaluates to the same string value. If *var* is missing, `$0` and `NF` will be set; otherwise, *var* will be set.

The `getline` operator can form ambiguous constructs when there are binary operators that are not in parentheses (including concatenate) to the right of the `<` (up to the end of the expression containing the `getline`). The result of evaluating such a construct is unspecified, and all such uses of portable applications must be put in parentheses properly.

nawk(1)

`system(expression)`

Execute the command given by *expression* in a manner equivalent to the `system(3C)` function and return the exit status of the command.

All forms of `getline` will return 1 for successful input, 0 for end of file, and -1 for an error.

Where strings are used as the name of a file or pipeline, the strings must be textually identical. The terminology "same string value" implies that "equivalent strings", even those that differ only by space characters, represent different files.

User-defined Functions

The nawk language also provides user-defined functions. Such functions can be defined as:

`function name(args, . . .) { statements }` A function can be referred to anywhere in an nawk program; in particular, its use can precede its definition. The scope of a function will be global.

Function arguments can be either scalars or arrays; the behavior is undefined if an array name is passed as an argument that the function uses as a scalar, or if a scalar expression is passed as an argument that the function uses as an array. Function arguments will be passed by value if scalar and by reference if array name. Argument names will be local to the function; all other variable names will be global. The same name will not be used as both an argument name and as the name of a function or a special nawk variable. The same name must not be used both as a variable name with global scope and as the name of a function. The same name must not be used within the same scope both as a scalar variable and as an array.

The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars will be initialized with a string value of the null string and a numeric value of zero, and the extra parameters that are used in the function body as arrays will be initialized as empty arrays. If more arguments are supplied in a function call than are in the function definition, the behavior is undefined.

When invoking a function, no white space can be placed between the function name and the opening parenthesis. Function calls can be nested and recursive calls can be made upon functions. Upon return from any nested or recursive function call, the values of all of the calling function's parameters will be unchanged, except for array parameters passed by reference. The `return` statement can be used to return a value. If a `return` statement appears outside of a function definition, the behavior is undefined.

In the function definition, newline characters are optional before the opening brace and after the closing brace. Function definitions can appear anywhere in the program where a *pattern-action* pair is allowed.

USAGE The `index`, `length`, `match`, and `substr` functions should not be confused with similar functions in the ISO C standard; the `nawk` versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

See `largefile(5)` for the description of the behavior of `nawk` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES The `nawk` program specified in the command line is most easily specified within single-quotes (for example, `'program'`) for applications using `sh`, because `nawk` programs commonly contain characters that are special to the shell, including double-quotes. In the cases where a `nawk` program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
awk '/'\''/ { print "quote:", $0 }'
```

prints all lines from the standard input containing a single-quote character, prefixed with `quote :`.

The following are examples of simple `nawk` programs:

EXAMPLE 1 Write to the standard output all input lines for which field 3 is greater than 5:

```
$3 > 5
```

EXAMPLE 2 Write every tenth line:

```
(NR % 10) == 0
```

EXAMPLE 3 Write any line with a substring matching the regular expression:

```
/(G|D)(2[0-9][[:alpha:]]*)/
```

EXAMPLE 4 Print any line with a substring containing a G or D, followed by a sequence of digits and characters:

This example uses character classes `digit` and `alpha` to match language-independent digit and alphabetic characters, respectively.

```
/(G|D)([[:digit:]][[:alpha:]]*)/
```

nawk(1)

EXAMPLE 4 Print any line with a substring containing a G or D, followed by a sequence of digits and characters: *(Continued)*

EXAMPLE 5 Write any line in which the second field matches the regular expression and the fourth field does not:

```
$2 ~ /xyz/ && $4 !~ /xyz/
```

EXAMPLE 6 Write any line in which the second field contains a backslash:

```
$2 ~ /\
```

EXAMPLE 7 Write any line in which the second field contains a backslash (alternate method):

Note that backslash escapes are interpreted twice, once in lexical processing of the string and once in processing the regular expression.

```
$2 ~ "\\
```

EXAMPLE 8 Write the second to the last and the last field in each line, separating the fields by a colon:

```
{OFS=":";print $(NF-1), $NF}
```

EXAMPLE 9 Write the line number and number of fields in each line:

The three strings representing the line number, the colon and the number of fields are concatenated and that string is written to standard output.

```
{print NR ":" NF}
```

EXAMPLE 10 Write lines longer than 72 characters:

```
{length($0) > 72}
```

EXAMPLE 11 Write first two fields in opposite order separated by the OFS:

```
{ print $2, $1 }
```

EXAMPLE 12 Same, with input fields separated by comma or space and tab characters, or both:

```
BEGIN { FS = ", [\t]*| [\t]+" }  
{ print $2, $1 }
```

EXAMPLE 13 Add up first column, print sum and average:

```
{s += $1 }  
END {print "sum is ", s, " average is", s/NR}
```

EXAMPLE 13 Add up first column, print sum and average: *(Continued)*

EXAMPLE 14 Write fields in reverse order, one per line (many lines out for each line in):

```
{ for (i = NF; i > 0; --i) print $i }
```

EXAMPLE 15 Write all lines between occurrences of the strings “start” and “stop”:

```
/start/, /stop/
```

EXAMPLE 16 Write all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

EXAMPLE 17 Simulate the echo command:

```
BEGIN {
    for (i = 1; i < ARGV; ++i)
        printf "%s%s", ARGV[i], i==ARGV-1?"\n":""
}
```

EXAMPLE 18 Write the path prefixes contained in the PATH environment variable, one per line:

```
BEGIN {
    n = split (ENVIRON["PATH"], path, ":")
    for (i = 1; i <= n; ++i)
        print path[i]
}
```

EXAMPLE 19 Print the file “input”, filling in page numbers starting at 5:

If there is a file named `input` containing page headers of the form

```
Page#
```

and a file named `program` that contains

```
/Page/{ $2 = n++; }
{ print }
```

then the command line

```
nawk -f program n=5 input
```

will print the file `input`, filling in page numbers starting at 5.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect execution: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`LC_NUMERIC` Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values and formatting numeric output. Regardless of locale, the period

nawk(1)

character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing `awk` programs (including assignments in command-line arguments).

EXIT STATUS The following exit values are returned:

0 All input files were processed successfully.
>0 An error occurred.

The exit status can be altered within the program by using an `exit` expression.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

/usr/bin/nawk

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

/usr/xpg4/bin/awk

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Aho, A. V., B. W. Kernighan, and P. J. Weinberger, *The AWK Programming Language*, Addison-Wesley, 1988.

DIAGNOSTICS If any *file* operand is specified and the named file cannot be accessed, `nawk` will write a diagnostic message to standard error and terminate without any further action.

If the program specified by either the *program* operand or a *profile* operand is not a valid `nawk` program (as specified in `EXTENDED DESCRIPTION`), the behavior is undefined.

NOTES Input white space is not preserved on output if fields are involved.

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate the null string (" ") to it.

NAME	nca, snca – the Solaris Network Cache and Accelerator (NCA)	
DESCRIPTION	<p>The Solaris Network Cache and Accelerator (“NCA”) is a kernel module designed to provide improved web server performance. The kernel module, <code>ncakmod</code>, services HTTP requests. To improve the performance of servicing HTTP requests, the NCA kernel module maintains an in-kernel cache of web pages. If the NCA kernel module cannot service the request itself, it passes the request to the <code>http</code> daemon (<code>httpd</code>). It uses either a sockets interface, with family type designated <code>PF_NCA</code>, or a private Solaris doors interface that is based on the Solaris doors RPC mechanism, to pass the request.</p> <p>To use the sockets interface, the web server must open a socket of family type <code>PF_NCA</code>. The <code>PF_NCA</code> family supports only <code>SOCK_STREAM</code> and protocol 0, otherwise an error occurs.</p> <p>The following features are not presently supported:</p> <ul style="list-style-type: none"> ■ You cannot initiate a connection from a <code>PF_NCA</code> type socket. The <code>connect(3SOCKET)</code> interface on <code>PF_NCA</code> will fail. ■ System calls that are associated with type <code>SO_DGRAM</code>, such as <code>send()</code>, <code>sendto()</code>, <code>sendmsg()</code>, <code>recv()</code>, <code>recvfrom()</code>, and <code>recvmsg()</code>, will fail. ■ You cannot set TCP or IP options on a <code>PF_NCA</code> type socket through <code>setsockopt(3SOCKET)</code>. <p>The NCA cache consistency is maintained by honoring HTTP headers that deal with a given content type and expiration date, much the same way as a proxy cache.</p> <p>For configuration information, see <i>System Administration Guide, Volume 3</i></p> <p>When native <code>PF_NCA</code> socket support does not exist in the web server, the <code>ncad_addr(4)</code> interface must be used to provide NCA support in that web server.</p> <p>NCA is intended to be run on a dedicated web server. Running other large processes while running NCA might cause undesirable behavior.</p> <p>NCA supports the logging of in-kernel cache hits. See <code>ncalogd.conf(4)</code>. NCA stores logs in a binary format. Use the <code>ncab2clf(1)</code> utility to convert the log from a binary format to the Common Log File format.</p>	
FILES	<code>/etc/nca/ncakmod.conf</code>	Lists configuration parameters for NCA.
	<code>/etc/nca/ncalogd.conf</code>	Lists configuration parameters for NCA logging.
	<code>/etc/nca/nca.if</code>	Lists the physical interfaces on which NCA will run.
	<code>/etc/hostname.{}{0-9}</code>	Lists all physical interfaces configured on the server.

nca(1)

/etc/hosts

Lists all host names associated with the server. Entries in this file must match with entries in /etc/hostname. { } {0-9} for NCA to function.

System Administration Guide, Volume 3

NAME	ncab2clf – convert binary log file to Common Log File format
SYNOPSIS	<code>/usr/bin/ncab2clf [-Dhv] [-i <i>input-file</i>] [-o <i>output-file</i>] [-b <i>size</i>] [-n <i>number</i>] [-s <i>datetime</i>]</code>
DESCRIPTION	The <code>ncab2clf</code> command is used to convert the log file generated by the Solaris Network Cache and Accelerator (“NCA”) from binary format, to Common Log File (“CLF”) format. If no <i>input-file</i> is specified, <code>ncab2clf</code> uses <code>stdin</code> . If no <i>output-file</i> is specified, the output goes to <code>stdout</code> .
OPTIONS	<p><code>-b</code> Specifies the binary-log-file blocking in kilobytes; the default is 64 Kbyte.</p> <p><code>-D</code> Specifies that direct I/O be disabled.</p> <p><code>-h</code> Prints usage message.</p> <p><code>-i <i>input-file</i></code> Specifies the input file.</p> <p><code>-n <i>number</i></code> Output <i>number</i> CLF records.</p> <p><code>-o <i>output-file</i></code> Specifies the output file.</p> <p><code>-s <i>datetime</i></code> Skip any records before the date and time specified in <i>datetime</i>. You can specify the date and time in CLF format or in the format specified by the <code>touch(1)</code> utility. CLF format is the dominant format, so <code>ncab2clf</code> first analyzes <i>datetime</i> assuming CLF.</p> <p><code>-v</code> Provides verbose output.</p>
EXAMPLES	<p>EXAMPLE 1 Converting a Binary File to a Common Log File Format</p> <p>The following example converts the binary file <code>/var/nca/logs/nca.blf</code> to a file <code>/var/nca/logs/nca.clf</code>, which is in Common Log File format.</p> <pre>example% ncab2clf -D -i /var/nca/logs/nca.blf -o /var/nca/logs/nca.clf</pre> <p>EXAMPLE 2 Converting Multiple Log Files</p> <p>The following script may be used to convert multiple log files. The directory designated by “*” must only contain log files.</p> <pre>#!/bin/ksh for filename in * do ncab2clf -D < \$filename > \$filename.clf done</pre> <p>EXAMPLE 3 Using <code>-s</code> and <code>-n</code> on a Raw Device</p> <p>The following example shows how <code>ncab2clf</code> can be used on a raw device. If not using the <code>-n</code> option, the default is to convert all records from the starting location to the end of the file. The date and time specified with <code>-s</code>, below, is in CLF format.</p>

ncab2clf(1)

EXAMPLE 3 Using `-s` and `-n` on a Raw Device (Continued)

```
example% ncab2clf -s '10/Apr/2001:09:23:13' -n 100 < /dev/dsk/c2t1d0s6
```

EXIT STATUS The following exit values are returned:

0 The file converted successfully
>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWncau
Interface Stability	Evolving

SEE ALSO `nca(1)`, `ncakmod(1)`, `nca.if(4)`, `ncakmod.conf(4)`, `ncalogd.conf(4)`, `attributes(5)`

System Administration Guide, Volume 3

NOTES The binary log files generated by NCA can become very large. When converting these large binary files, use the `-b` option to the `ncab2clf` command to help performance.

Direct I/O is a benefit to the user if the data being written does not come in as large chunks. However, if the user wishes to convert the log file in large chunks using the `-b` option, then direct I/O should be disabled by using the `-D` option.

NAME	ncakmod – start or stop the NCA kernel module						
SYNOPSIS	<code>/etc/init.d/ncakmod start stop</code>						
DESCRIPTION	<p>ncakmod is used to start or stop the Solaris Network Cache and Accelerator (“NCA”) kernel module.</p> <p>When the <code>start</code> option is specified at the command-line, the NCA kernel module will be activated for all physical interfaces listed in the <code>nca.if</code> file. When the <code>ncakmod</code> command is invoked with the <code>stop</code> option, the NCA kernel module will print the following message:</p> <pre>To stop NCA, please set the status configuration parameter to disable in ncakmod.conf and then reboot your system. See the ncakmod.conf(4) manual page for more information.</pre> <p>Note that in order to properly stop NCA on your system, you must first edit the <code>ncakmod.conf(4)</code> file and set the status field to “disable,” then reboot your system.</p>						
OPTIONS	<p><code>start</code> Starts the NCA kernel module.</p> <p><code>stop</code> Describes the current method for stopping the NCA feature.</p>						
EXAMPLES	<p>EXAMPLE 1 Starting and Stopping the NCA Feature</p> <p>The following command is used to start the NCA feature:</p> <pre>example% /etc/init.d/ncakmod start</pre>						
FILES	<p><code>/etc/init.d/ncakmod</code> The NCA kernel module startup script.</p> <p><code>/etc/nca/ncakmod.conf</code> Specifies configuration options for the NCA kernel module.</p>

netscape(1)

NAME	netscape – start Netscape Communicator for Solaris
SYNOPSIS	<code>/usr/dt/bin/netscape</code> [options] [arguments]
DESCRIPTION	Netscape Communicator for Solaris is comprised of a comprehensive set of components that integrates browsing, email, web-based word processing, chat, and group scheduling to allow users to easily communicate, share, and access information.
OPTIONS	<p>Any argument that is not a switch is interpreted as either a file or URL. The following options are supported:</p> <ul style="list-style-type: none">-component-bar Shows only the Component Bar.-composer Opens all command line URLs in Composer.-discussions Shows Collabra Discussions.-display <i>dpy</i> Specifies the X server to use for display.-dont-force-window-stacking Ignores the alwaysraised, alwayslowered, and z-lock JavaScript <code>window.open()</code> attributes.-dont-save-geometry-prefs Does not save window geometry preferences for the session.-edit See -composer.-geometry =<i>WxH+X+Y</i> Positions and sizes the Netscape window.-help Shows the command line options for Netscape.-iconic Minimizes Netscape after start up.-id <i>window-id</i> Identifies an X window to receive -remote commands. If you do not specify a window, the first window found is used.-ignore-geometry-prefs Ignores saved window geometry preferences for the current session.-install Installs private colormap.

- `-irix-session-management`
Enables IRIX session management. On SGI systems, IRIX session management is enabled by default. IRIX session management is available on other platforms and may work with session managers other than the IRIX desktop. See `-no-irix-session-management`.
- `-mail`
Same as `-messenger`.
- `-messenger`
Shows the Messenger Mailbox (Inbox).
- `-mono`
Forces a one-bit deep image display.
- `-ncols N`
Sets the maximum number of colors to allocate for images when not using `-install`.
- `-nethelp`
Starts NetHelp, Netscape's online help system.
- `-news`
Same as `-discussions`.
- `-no-about-splash`
Bypasses the startup license page.
- `-no-install`
Uses the default colormap.
- `-no-irix-session-management`
Disables IRIX session management. See `-irix-session-management`.
- `-no-session-management`
Disables session management. Session management is enabled by default. See `-session-management`.
- `-noraise`
Does not display the remote window on top when using `-remote` commands. See `-raise` and `-remote`.
- `-raise`
Displays the remote window on top when using `-remote` commands. See `-noraise` and `-remote`.
- `-remote remote-command`
Connects to and controls an existing process. You can issue multiple `-remote` options on the same command line. The commands are executed sequentially unless a command fails. If there is no Netscape process currently running, this command fails. If the command fails, an error message will be reported to `stderr` and it will exit with a nonzero status. See REMOTE ACTIONS section below and EXAMPLES.

netscape(1)

The following options exist for finer-grained control of the `-remote` commands:

- `-id X_window_ID` If there is more than one Netscape Navigator window open, this option selects the window to control. If you do not use this option, the first window found is controlled. See EXAMPLES.
- `-raise`
`-noraise` Controls whether the `-remote` command causes the Netscape window to raise/not raise itself to the top. The default is raise.

You can use `-raise` and `-noraise` options with the `addBookmark` and `openURL` arguments. See EXAMPLES.
- `-session-management`
Enables session management. Session management is enabled by default. See `-no-session-management`.
- `-version`
Displays the version number and build date.
- `-visual id-or-number`
Uses the specified server visual.
- `-xrm resource-spec`
Sets the specified X resource.

REMOTE ACTIONS

When Netscape Navigator is invoked with the `-remote` argument, it does not open a window, but instead connects to and controls an already existing process. The argument to the `-remote` switch is an Xt action to invoke, with optional arguments. Remote control is implemented using X properties, so the two processes need not be running on the same machine, and need not share a file system. See <http://home.netscape.com/newsref/std/x-remote.html>.

All of Netscape's action names are the same as its resource names. For example, if you wanted to know the name of the action that corresponds to the "Add Bookmark" menu item, you could look in Netscape for "Add Bookmark" and see that the resource that is set to that string is `addBookmark`. That is the name of the Action as well. *Note:* To find the Netscape file, use the full path name which is, by default, `/usr/dt/appconfig/netscape/lib/locale/C/app-defaults/Netscape`.

You can use Actions in Translation tables in the usual Xt manner, but you can also invoke them directly via the `-remote` option, like this:

```
netscape -remote 'addBookmark()' That command will cause the existing Netscape Navigator process to add its current URL to the bookmarks, just as if you had selected that menu item.
```

To open a document, enter:

```
netscape -remote 'openURL(http://home.netscape.com)'
```

Invoking an action with no arguments has the same effect as selecting the corresponding menu item. However, with some actions you can pass the following arguments:

<code>addBookmark()</code>	Adds the current document to the Bookmark list.
<code>addBookmark(URL)</code>	Adds the specified document to the Bookmark list. See EXAMPLES.
<code>addBookmark(URL, title)</code>	Adds the specified document and title to the Bookmark list.
<code>mailto()</code>	Opens the mail dialog box with an empty To: field.
<code>mailto(a, b, c)</code>	Inserts the specified address(es) in the default To: field.
<code>openFile()</code>	Opens a dialog box that prompts for a file.
<code>openFile(filename)</code>	Opens the specified file.
<code>openURL()</code>	Opens a dialog box that prompts for a URL.
<code>openURL(URL)</code>	Opens the specified document. See EXAMPLES.
<code>openURL(URL, new window)</code>	Opens a new window displaying the specified document.
<code>saveAs()</code>	Opens a dialog box that prompts for a URL.
<code>saveAs(output_file)</code>	Writes HTML to the specified file.
<code>saveAs(output_file, type)</code>	Writes the <i>type</i> to the specified file (HTML, text, or PostScript).

EXIT STATUS If a command fails, an error message is reported to stderr and the command exits with a nonzero status.

EXAMPLES The following are all examples of using the `-remote` command option. For more information and examples, see <http://home.netscape.com/newsref/std/x-remote.html>

EXAMPLE 1 Selecting among open Netscape windows

```
example% netscape -id 0x3c00124 -remote 'openURL(http://www.sun.com)'
```

netscape(1)

EXAMPLE 2 Adding a bookmark without raising a window

To add a bookmark without raising a window, followed by opening a URL and raising the window, enter:

```
example% netscape -noraise -remote 'addBookmark(http://www.sun.com)' \  
-raise -remote 'openURL(http://home.netscape.com)'
```

EXAMPLE 3 Adding a specified document to the Bookmark list

```
example% netscape -remote 'addBookmark(http://www.sun.com)'
```

EXAMPLE 4 Opening a specified document

```
example% netscape -remote 'openURL(http://www.sun.com)'
```

ATTRIBUTES

NAME	newform – change the format of a text file
SYNOPSIS	newform [-s] [-itabspec] [-otabspec] [-bn] [-en] [-pn] [-an] [-f] [-cchar] [-ln] [filename...]
DESCRIPTION	<p>newform reads lines from the named <i>filenames</i>, or the standard input if no input file is named, and reproduces the lines on the standard output. Lines are reformatted in accordance with command line options in effect.</p> <p>Except for -s, command line options may appear in any order, may be repeated, and may be intermingled with the optional <i>filenames</i>. Command line options are processed in the order specified. This means that option sequences like “-e15 -160” will yield results different from “-160 -e15”. Options are applied to all <i>filenames</i> on the command line.</p>
OPTIONS	<p>The following options are supported:</p> <p>-s Shears off leading characters on each line up to the first tab and places up to 8 of the sheared characters at the end of the line. If more than 8 characters (not counting the first tab) are sheared, the eighth character is replaced by a * and any characters to the right of it are discarded. The first tab is always discarded.</p> <p>An error message and program exit will occur if this option is used on a file without a tab on each line. The characters sheared off are saved internally until all other options specified are applied to that line. The characters are then added at the end of the processed line.</p> <p>For example, to convert a file with leading digits, one or more tabs, and text on each line, to a file beginning with the text, all tabs after the first expanded to spaces, padded with spaces out to column 72 (or truncated to column 72), and the leading digits placed starting at column 73, the command would be:</p> <pre>newform -s -i -l -a -e filename</pre> <p>-itabspec Input tab specification: expands tabs to spaces, according to the tab specifications given. <i>Tabspec</i> recognizes all tab specification forms described in tabs(1). In addition, <i>tabspec</i> may be -, in which newform assumes that the tab specification is to be found in the first line read from the standard input (see fspec(4)). If no <i>tabspec</i> is given, <i>tabspec</i> defaults to -8. A <i>tabspec</i> of -0 expects no tabs; if any are found, they are treated as -1.</p> <p>-otabspec Output tab specification: replaces spaces by tabs, according to the tab specifications given. The tab specifications are the same as for -itabspec. If no <i>tabspec</i> is given, <i>tabspec</i> defaults to -8. A <i>tabspec</i> of -0 means that no spaces will be converted to tabs on output.</p>

newform(1)

- bn Truncate *n* characters from the beginning of the line when the line length is greater than the effective line length (see *-ln*). Default is to truncate the number of characters necessary to obtain the effective line length. The default value is used when *-b* with no *n* is used. This option can be used to delete the sequence numbers from a COBOL program as follows:

newform -l1 -b7 *filename*
- en Same as *-bn* except that characters are truncated from the end of the line.
- pn Prefix *n* characters (see *-cchar*) to the beginning of a line when the line length is less than the effective line length. Default is to prefix the number of characters necessary to obtain the effective line length.
- an Same as *-pn* except characters are appended to the end of a line.
- f Write the tab specification format line on the standard output before any other lines are output. The tab specification format line which is printed will correspond to the format specified in the last *-o* option. If no *-o* option is specified, the line which is printed will contain the default specification of *-8*.
- cchar Change the prefix/append character to *char*. Default character for *char* is a space.
- ln Set the effective line length to *n* characters. If *n* is not entered, *-l* defaults to 72. The default line length without the *-l* option is 80 characters. Note: Tabs and backspaces are considered to be one character (use *-i* to expand tabs to spaces).

The *-l1* must be used to set the effective line length shorter than any existing line in the file so that the *-b* option is activated.

OPERANDS The following operand is supported:

filename Input file

EXIT STATUS The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
----------------	-----------------

Availability	SUNWesu
--------------	---------

SEE ALSO `csplit(1)`, `tabs(1)`, `fspec(4)`, `attributes(5)`

DIAGNOSTICS All diagnostics are fatal.

```
usage: . . .
    newform was called with a bad option.

"not -s format"
    There was no tab on one line.

"can't open file"
    Self-explanatory.

"internal line too long"
    A line exceeds 512 characters after being expanded in the internal work buffer.

"tabspec in error"
    A tab specification is incorrectly formatted, or specified tab stops are not ascending.

"tabspec indirection illegal"
    A tabspec read from a file (or standard input) may not contain a tabspec referencing
    another file (or standard input).
```

NOTES `newform` normally only keeps track of physical characters; however, for the `-i` and `-o` options, `newform` will keep track of backspaces in order to line up tabs in the appropriate logical columns.

`newform` will not prompt the user if a *tabspec* is to be read from the standard input (by use of `-i-` or `-o-`).

If the `-f` option is used, and the last `-o` option specified was `-o-`, and was preceded by either a `-o-` or a `-i-`, the tab specification format line will be incorrect.

newgrp(1)

NAME	newgrp – log in to a new group
Command	<code>/usr/bin/newgrp [- -1] [group]</code>
sh Built-in	<code>newgrp [argument]</code>
ksh Built-in	<code>*newgrp [argument]</code>
Command	<p>The <code>newgrp</code> command logs a user into a new group by changing a user's real and effective group ID. The user remains logged in and the current directory is unchanged. The execution of <code>newgrp</code> always replaces the current shell with a new shell, even if the command terminates with an error (unknown group).</p> <p>Any variable that is not exported is reset to null or its default value. Exported variables retain their values. System variables (such as <code>PS1</code>, <code>PS2</code>, <code>PATH</code>, <code>MAIL</code>, and <code>HOME</code>), are reset to default values unless they have been exported by the system or the user. For example, when a user has a primary prompt string (<code>PS1</code>) other than <code>\$</code> (default) and has not exported <code>PS1</code>, the user's <code>PS1</code> will be set to the default prompt string <code>\$</code>, even if <code>newgrp</code> terminates with an error. Note that the shell command <code>export</code> (see <code>sh(1)</code> and <code>set(1)</code>) is the method to export variables so that they retain their assigned value when invoking new shells.</p> <p>With no operands and options, <code>newgrp</code> changes the user's group IDs (real and effective) back to the group specified in the user's password file entry. This is a way to exit the effect of an earlier <code>newgrp</code> command.</p> <p>A password is demanded if the group has a password and the user is not listed in <code>/etc/group</code> as being a member of that group. The only way to create a password for a group is to use <code>passwd(1)</code>, then cut and paste the password from <code>/etc/shadow</code> to <code>/etc/group</code>. Group passwords are antiquated and not often used.</p>
sh Built-in	Equivalent to <code>exec newgrp argument</code> where <i>argument</i> represents the options and/or operand of the <code>newgrp</code> command.
ksh Built-in	Equivalent to <code>exec to/bin/newgrp argument</code> where <i>argument</i> represents the options and/or operand of the <code>newgrp</code> command.
	<p>On this man page, <code>ksh(1)</code> commands that are preceded by one or two * (asterisks) are treated specially in the following ways:</p> <ol style="list-style-type: none">1. Variable assignment lists preceding the command remain in effect when the command completes.2. I/O redirections are processed after variable assignments.3. Errors cause a script that contains them to abort.4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.
OPTIONS	The following option is supported:

- 1 | -

Change the environment to what would be expected if the user actually logged in again as a member of the new group.

OPERANDS	<p>The following operands are supported:</p> <p><i>group</i> A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs will be set. If <i>group</i> is a non-negative numeric string and exists in the group database as a group name (see <code>getgrnam(3C)</code>), the numeric group ID associated with that group name will be used as the group ID.</p> <p><i>argument</i> <code>sh</code> and <code>ksh</code> only. Options and/or operand of the <code>newgrp</code> command.</p>						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>newgrp</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS	<p>If <code>newgrp</code> succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status will be the exit status of the shell. Otherwise, the following exit value is returned:</p> <p>>0 An error occurred.</p>						
FILES	<p><code>/etc/group</code> system's group file</p> <p><code>/etc/passwd</code> system's password file</p>						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>Interface Stability</td> <td>Standard</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	Interface Stability	Standard

news(1)

NAME news – print news items

SYNOPSIS **news** [-a] [-n] [-s] [*items*]

DESCRIPTION news is used to keep the user informed of current events. By convention, these events are described by files in the directory `/var/news`.

When invoked without arguments, news prints the contents of all current files in `/var/news`, most recent first, with each preceded by an appropriate header. news stores the “currency” time as the modification date of a file named `.news_time` in the user’s home directory (the identity of this directory is determined by the environment variable `$HOME`); only files more recent than this currency time are considered “current.”

OPTIONS

- a Print all items, regardless of currency. In this case, the stored time is not changed.
- n Report the names of the current items without printing their contents, and without changing the stored time.
- s report how many current items exist, without printing their names or contents, and without changing the stored time. It is useful to include such an invocation of news in one’s `.profile` file, or in the system’s `/etc/profile`.

All other arguments are assumed to be specific news items that are to be printed.

If a *delete* is typed during the printing of a news item, printing stops and the next item is started. Another *delete* within one second of the first causes the program to terminate.

ENVIRONMENT VARIABLES See `environ(5)` for a description of the `LC_CTYPE` environment variable that affects the execution of news.

FILES `/etc/profile`
`/var/news/*`
`$HOME/.news_time`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled

SEE ALSO `profile(4)`, `attributes(5)`, `environ(5)`

NAME	newtask – create new task or change task or project of running process
SYNOPSIS	newtask [-c <i>pid</i> [-F1] [<i>command...</i>]] [-p <i>project</i>] [-v]
DESCRIPTION	<p>The <code>newtask</code> command executes the user's default shell or a specified command, placing the executed command in a new task owned by the specified project. The user's default shell is the one specified in the <code>passwd</code> database, and is determined via <code>getpwnam()</code>.</p> <p>Alternatively, <code>newtask</code> may be used to change the task of an already running process. A project may also be specified in this form of the command. This may be desirable for processes that are mission critical and cannot be restarted in order to put them into a new project.</p> <p>In the case that extended accounting is active, the <code>newtask</code> command may additionally cause the creation of a task accounting record marking the completion of the preceding system task.</p>
OPTIONS	<p>The following options are supported:</p> <p>-c <i>pid</i> Changes the task or project of a running process. The invoking user must either own the process or have super-user privileges.</p> <p>If the project is being changed, the process owner must be a member of the specified project, or the invoking user must have super-user privileges. When the project is changed for a running process, its pool binding as well as resource controls are modified to match the configuration of the new project. Controls not explicitly specified in the project entry will be preserved.</p> <p>This option is incompatible with the <code>-F</code> and <code>-l</code> options.</p> <p>-F Creates a finalized task, within which further <code>newtask</code> or <code>settaskid(2)</code> invocations would fail. Finalized tasks may be useful at some sites for simplifying the attribution of resource consumption.</p> <p>-l Changes the environment to what would be expected if the user actually logged in again as a member of the new project.</p> <p>-p Changes the project ID of the new task to that associated with the given project name. The invoking user must be a valid member of the requested project, or must have super-user privileges, for the command to succeed. If no project name is specified, the new task is started in the invoking user's current project.</p> <p>-v Verbose: displays the system task id as the new system task is begun.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>project</i> The project to which resource usage by the created task should be charged. The requested project must be defined in the project databases defined in <code>nsswitch.conf(4)</code>.</p>

newtask(1)

command The command to be executed as the new task. If no command is given, the user's login shell is invoked. (If the login shell is not available, /bin/sh is invoked.)

EXAMPLES **EXAMPLE 1** Creating a new shell

The following example creates a new shell in the `canada` project, displaying the task id:

```
example$ id -p
uid=565(gh) gid=10(staff) projid=10(default)
example$ newtask -v -p canada
38
example$ id -p
uid=565(gh) gid=10(staff) projid=82(canada)
```

EXAMPLE 2 Running the date command

The following example runs the `date` command in the `russia` project:

```
example$ newtask -p russia date
Tue Aug 31 11:12:10 PDT 1999
```

EXAMPLE 3 Changing the project of an existing process

The following example changes the project of the existing process with a pid of 9999 to `russia`:

```
example$ newtask -c 9999 -p russia
```

EXIT STATUS The following exit values are returned:

- 0 Successful execution.
- 1 A fatal error occurred during execution.
- 2 Invalid command line options were specified.

FILES /etc/project Local database containing valid project definitions for this machine.

/proc/pid/* Process information and control files.

nice(1)

NAME	nice – invoke a command with an altered scheduling priority
SYNOPSIS	<p><code>/usr/bin/nice [-increment -n increment] command [argument...]</code></p> <p><code>/usr/xpg4/bin/nice [-increment -n increment] command [argument...]</code></p>
csH Builtin	<code>nice [-increment +increment] [command]</code>
DESCRIPTION	<p>The <code>nice</code> utility invokes <code>command</code>, requesting that it be run with a different system scheduling priority. The <code>priocntl(1)</code> command is a more general interface to scheduler functions.</p> <p>The invoking process (generally the user’s shell) must be in a scheduling class that supports <code>nice</code>.</p> <p>If the C shell (see <code>csH(1)</code>) is used, the full path of the command must be specified; otherwise, the <code>csH</code> built-in version of <code>nice</code> will be invoked. See <code>csH Builtin</code> below.</p>
/usr/bin/nice	If <code>nice</code> executes commands with arguments, it uses the default shell <code>/usr/bin/sh</code> (see <code>sh(1)</code>).
/usr/xpg4/bin/nice	If <code>nice</code> executes commands with arguments, it uses <code>/usr/xpg4/bin/sh</code> (see <code>ksh(1)</code>).
csH Builtin	<code>nice</code> is also a <code>csH</code> built-in command with behavior different from the utility versions. See <code>csH(1)</code> for description.
OPTIONS	<p>The following options are supported:</p> <p><code>-increment -n increment</code></p> <p><i>increment</i> must be in the range 1-19; if not specified, an increment of 10 is assumed. An <i>increment</i> greater than 19 is equivalent to 19.</p> <p>The super-user may run commands with priority higher than normal by using a negative increment such as -10. A negative <i>increment</i> assigned by an unprivileged user is ignored.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>command</i> The name of a command that is to be invoked. If <i>command</i> names any of the special built-in utilities (see <code>shell_builtins(1)</code>), the results are undefined.</p> <p><i>argument</i> Any string to be supplied as an argument when invoking <i>command</i>.</p>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>nice</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , <code>PATH</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>If <i>command</i> is invoked, the exit status of <code>nice</code> will be the exit status of <i>command</i>. Otherwise, <code>nice</code> will exit with one of the following values:</p> <p>1-125 An error occurred.</p>

126 *command* was found but could not be invoked.

127 *command* could not be found.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

nis+(1)

NAME	nis+, NIS+, nis – a new version of the network information name service
DESCRIPTION	<p>NIS+ is a new version of the network information nameservice. This version differs in several significant ways from version 2, which is referred to as NIS or YP in earlier releases. Specific areas of enhancement include the ability to scale to larger networks, security, and the administration of the service.</p> <p>The man pages for NIS+ are broken up into three basic categories. Those in section 1 are the user commands that are most often executed from a shell script or directly from the command line. Section 1M man pages describe utility commands that can be used by the network administrator to administer the service itself. The NIS+ programming API is described by man pages in section 3NSL.</p> <p>All commands and functions that use NIS version 2 are prefixed by the letters <i>yp</i> as in <i>ypmatch(1)</i>, <i>ypcat(1)</i>, <i>yp_match(3NSL)</i>, and <i>yp_first(3NSL)</i>. Commands and functions that use the new replacement software NIS+ are prefixed by the letters <i>nis</i> as in <i>nismatch(1)</i>, <i>nischown(1)</i>, <i>nis_list(3NSL)</i>, and <i>nis_add_entry(3NSL)</i>. A complete list of NIS+ commands is in the LIST OF COMMANDS section.</p> <p>This man page introduces the NIS+ terminology. It also describes the NIS+ namespace, authentication, and authorization policies.</p>
NIS+ NAMESPACE	The naming model of NIS+ is based upon a tree structure. Each node in the tree corresponds to an NIS+ object. There are six types of NIS+ objects: <i>directory</i> , <i>table</i> , <i>group</i> , <i>link</i> , <i>entry</i> , and <i>private</i> .
NIS+ Directory Object	Each NIS+ namespace will have at least one NIS+ directory object. An NIS+ directory is like a UNIX file system directory which contains other NIS+ objects including NIS+ directories. The NIS+ directory that forms the root of the NIS+ namespace is called the root directory. There are two special NIS+ directories: <i>org_dir</i> and <i>groups_dir</i> . The <i>org_dir</i> directory consists of all the system-wide administration tables, such as <i>passwd</i> , <i>hosts</i> , and <i>mail_aliases</i> . The <i>groups_dir</i> directory consists of NIS+ group objects which are used for access control. The collection of <i>org_dir</i> , <i>groups_dir</i> and their parent directory is referred to as an NIS+ domain. NIS+ directories can be arranged in a tree-like structure so that the NIS+ namespace can match the organizational or administrative hierarchy.
NIS+ Table Object	NIS+ tables (not files), contained within NIS+ directories, store the actual information about some particular type. For example, the <i>hosts</i> system table stores information about the IP address of the hosts in that domain. NIS+ tables are multicolumn and the tables can be searched through any of the searchable columns. Each table object defines the schema for its table. The NIS+ tables consist of NIS+ entry objects. For each entry in the NIS+ table, there is an NIS+ entry object. NIS+ entry objects conform to the schema defined by the NIS+ table object.
NIS+ Group Object	NIS+ group objects are used for access control at group granularity. NIS+ group objects, contained within the <i>groups_dir</i> directory of a domain, contain a list of all the NIS+ principals within a certain NIS+ group. An NIS+ principal is a user or a machine making NIS+ requests.

NIS+ Link Object	<p>NIS+ link objects are like UNIX symbolic file-system links—they are typically used for shortcuts in the NIS+ namespace.</p> <p>Refer to <code>nis_objects(3NSL)</code> for more information about the NIS+ objects.</p>
NIS+ NAMES	<p>The NIS+ service defines two forms of names, <i>simple</i> names and <i>indexed</i> names. Simple names are used by the service to identify NIS+ objects contained within the NIS+ namespace. Indexed names are used to identify NIS+ entries contained within NIS+ tables. Furthermore, entries within NIS+ tables are returned to the caller as NIS+ objects of type <i>entry</i>. NIS+ objects are implemented as a union structure which is described in the file <code><rpcsvc/nis_object.x></code>. The differences between the various types and the meanings of the components of these objects are described in <code>nis_objects(3NSL)</code>.</p>
Simple Names	<p>Simple names consist of a series of labels that are separated by the '.' (dot) character. Each label is composed of printable characters from the ISO Latin 1 set. Each label can be of any nonzero length, provided that the fully qualified name is fewer than <code>NIS_MAXNAMELEN</code> octets including the separating dots. (See <code><rpcsvc/nis.h></code> for the actual value of <code>NIS_MAXNAMELEN</code> in the current release.) Labels that contain special characters (see <code>Grammar</code>) must be quoted.</p> <p>The NIS+ namespace is organized as a singly rooted tree. Simple names identify nodes within this tree. These names are constructed such that the leftmost label in a name identifies the leaf node and all of the labels to the right of the leaf identify that object's parent node. The parent node is referred to as the leaf's <i>directory</i>. This is a naming directory and should not be confused with a file system directory.</p> <p>For example, the name <i>example.simple.name</i> is a simple name with three labels, where <i>example</i> is the leaf node in this name, the directory of this leaf is <i>simple.name</i> which by itself is a simple name. The leaf of which is <i>simple</i> and its directory is simply <i>name</i>.</p> <p>The function <code>nis_leaf_of(3NSL)</code> returns the first label of a simple name. The function <code>nis_domain_of(3NSL)</code> returns the name of the directory that contains the leaf. Iterative use of these two functions can break a simple name into each of its label components.</p> <p>The name '.' (dot) is reserved to name the <i>global root</i> of the namespace. For systems that are connected to the Internet, this global root will be served by a Domain Name Service. When an NIS+ server is serving a root directory whose name is not '.' (dot) this directory is referred to as a <i>local root</i>.</p> <p>NIS+ names are said to be <i>fully qualified</i> when the name includes all of the labels identifying all of the directories, up to the global root. Names without the trailing dot are called <i>partially</i> qualified.</p>
Indexed Names	<p>Indexed names are compound names that are composed of a search criterion and a simple name. The search criterion component is used to select entries from a table; the simple name component is used to identify the NIS+ table that is to be searched. The search criterion is a series of column names and their desired values enclosed in bracket '[']' characters. These criteria take the following form:</p>

nis+(1)

[*column_name=value, column_name =value, ...*]

A search criterion is combined with a simple name to form an indexed name by concatenating the two parts, separated by a ','(comma) character as follows.

[*search-criterion*] , *table.directory*

When multiple column name/value pairs are present in the search criterion, only those entries in the table that have the appropriate value in all columns specified are returned. When no column name/value pairs are specified in the search criterion, [] , *all* entries in the table are returned.

Grammar The following text represents a context-free grammar that defines the set of legal NIS+ names. The terminals in this grammar are the characters '.' (dot), '[' (open bracket), ']' (close bracket), ',' (comma), '=' (equals) and whitespace. Angle brackets ('<' and '>'), which delineate non-terminals, are not part of the grammar. The character '|' (vertical bar) is used to separate alternate productions and should be read as "this production OR this production".

<i>name</i>	::=	. <simple name> <indexed name>
<i>simple name</i>	::=	<string>. <string>.<simple name>
<i>indexed name</i>	::=	<search criterion>,<simple name>
<i>search criterion</i>	::=	[<attribute list>]
<i>attribute list</i>	::=	<attribute> <attribute>,<attribute list>
<i>attribute</i>	::=	<string> = <string>
<i>string</i>	::=	ISO Latin 1 character set except the character '/' (slash). The initial character may not be a terminal character or the characters '@' (at), '+' (plus), or '-' hyphen.

Terminals that appear in strings must be quoted with "" (double quote). The "" character may be quoted by quoting it with itself "" "".

Name Expansion The NIS+ service only accepts fully qualified names. However, since such names may be unwieldy, the NIS+ commands in section 1 employ a set of standard expansion rules that will attempt to fully qualify a partially qualified name. This expansion is actually done by the NIS+ library function `nis_getnames(3NSL)` which generates a list of names using the default NIS+ directory search path or the `NIS_PATH` environment variable. The default NIS+ directory search path includes all the names in its path. `nis_getnames()` is invoked by the functions `nis_lookup(3NSL)` and `nis_list(3NSL)` when the `EXPAND_NAME` flag is used.

The `NIS_PATH` environment variable contains an ordered list of simple names. The names are separated by the ':' (colon) character. If any name in the list contains colons, the colon should be quoted as described in the Grammar section. When the list is exhausted, the resolution function returns the error `NIS_NOTFOUND`. This may mask the fact that the name existed but a server for it was unreachable. If the name presented to the list or lookup interface is fully qualified, the `EXPAND_NAME` flag is ignored.

In the list of names from the `NIS_PATH` environment variable, the '\$' (dollar sign) character is treated specially. Simple names that end with the label '\$' have this character replaced by the default directory (see `nis_local_directory(3NSL)`). Using "\$" as a name in this list results in this name being replaced by the list of directories between the default directory and the global root that contain at least two labels.

Below is an example of this expansion. Given the default directory of *some.long.domain.name.*, and the `NIS_PATH` variable set to `fred.bar.:org_dir.$:$`. This path is initially broken up into the list:

```
1      fred.bar.
2      org_dir.$
3      $
```

The dollar sign in the second component is replaced by the default directory. The dollar sign in the third component is replaced with the names of the directories between the default directory and the global root that have at least two labels in them. The effective path value becomes:

```
1      fred.bar.
2a     org_dir.some.long.domain.name.
3a     some.long.domain.name.
3b     long.domain.name.
3c     domain.name.
```

Each of these simple names is appended to the partially qualified name that was passed to the `nis_lookup(3NSL)` or `nis_list(3NSL)` interface. Each is tried in turn until `NIS_SUCCESS` is returned or the list is exhausted.

If the `NIS_PATH` variable is not set, the path "\$" is used.

The library function `nis_getnames(3NSL)` can be called from user programs to generate the list of names that would be attempted. The program `nisdefaults(1)` with the `-s` option can also be used to show the fully expanded path.

Concatenation Path

Normally, all the entries for a certain type of information are stored within the table itself. However, there are times when it is desirable for the table to point to other tables where entries can be found. For example, you may want to store all the IP

nis+(1)

addresses in the host table for their own domain, and yet want to be able to resolve hosts in some other domain without explicitly specifying the new domain name. NIS+ provides a mechanism for concatenating different but related tables with a "NIS+ Concatenation Path". With a concatenation path, you can create a sort of flat namespace from a hierarchical structure. You can also create a table with no entries and just point the hosts or any other table to its parent domain. Note that with such a setup, you are moving the administrative burden of managing the tables to the parent domain. The concatenation path will slow down the request response time because more tables and more servers are searched. It will also decrease the availability if all the servers are incapacitated for a particular directory in the table path.

The NIS+ Concatenation Path is also referred to as the "table path". This path is set up at table creation time through `nistbladm(1)`. You can specify more than one table to be concatenated and they will be searched in the given order. Note that the NIS+ client libraries, by default, will not follow the concatenation path set in site-specific tables. Refer to `nis_list(3NSL)` for more details.

Namespaces

The NIS+ service defines two additional *disjoint* namespaces for its own use. These namespaces are the NIS+ *Principal* namespace, and the NIS+ *Group* namespace. The names associated with the group and principal namespaces are syntactically identical to simple names. However, the information they represent *cannot* be obtained by directly presenting these names to the NIS+ interfaces. Instead, special interfaces are defined to map these names into NIS+ names so that they may then be resolved.

Principal Names

NIS+ principal names are used to uniquely identify users and machines that are making NIS+ requests. These names have the form:

principal.domain

Here *domain* is the fully qualified name of an NIS+ directory where the named principal's credentials can be found. See *Directories* and *Domains* for more information on domains. Note that in this name, *principal*, is not a leaf in the NIS+ namespace.

Credentials are used to map the identity of a host or user from one context such as a process UID into the NIS+ context. They are stored as records in an NIS+ table named *cred*, which always appears in the *org_dir* subdirectory of the directory named in the principal name.

This mapping can be expressed as a replacement function:

```
principal.domain -> [cname=principal.domain ] , cred.org_dir.domain
```

This latter name is an NIS+ name that can be presented to the `nis_list(3NSL)` interface for resolution. NIS+ principal names are administered using the `nisaddcred(1M)` command.

The *cred* table contains five columns named *cname*, *auth_name*, *auth_type*, *public_data*, and *private_data*. There is one record in this table for each identity mapping for an NIS+ principal. The current service supports three types of mappings:

LOCAL	This mapping is used to map from the UID of a given process to the NIS+ principal name associated with that UID. If no mapping exists, the name <i>nobody</i> is returned. When the effective UID of the process is 0 (for example, the superuser), the NIS+ name associated with the host is returned. Note that UIDs are sensitive to the context of the machine on which the process is executing.
DES	This mapping is used to map to and from a Secure RPC "netname" into an NIS+ principal name. See <i>secure_rpc(3NSL)</i> for more information on netnames. Note that since netnames contain the notion of a domain, they span NIS+ directories.
DHnnn-m	Example: DH640-0, DH1024-0. Analogous to DES mappings, these are used to map netnames and NIS+ principal names for extended Diffie-Hellman keys. See <i>nisauthconf(1M)</i> for further information.

The NIS+ client library function *nis_local_principal(3NSL)* uses the *cred.org_dir* table to map the UNIX notion of an identity, a process' UID, into an NIS+ principal name. Shell programs can use the program *nisdefaults(1)* with the *-p* switch to return this information.

Mapping from UIDs to an NIS+ principal name is accomplished by constructing a query of the form:

```
[auth_type=LOCAL, auth_name=uid], cred.org_dir.default-domain.
```

This query will return a record containing the NIS+ principal name associated with this UID, in the machine's default domain.

The NIS+ service uses the DES mapping to map the names associated with Secure RPC requests into NIS+ principal names. RPC requests that use Secure RPC include the *netname* of the client making the request in the RPC header. This netname has the form:

```
unix.UID@domain
```

The service constructs a query using this name of the form:

```
[auth_type=DES, auth_name=netname], cred.org_dir.domain.
```

where the domain part is extracted from the netname rather than using the default domain. This query is used to look up the mapping of this netname into an NIS+ principal name in the domain where it was created.

nis+(1)

	<p>This mechanism of mapping UID and netnames into an NIS+ principal name guarantees that a client of the NIS+ service has only one principal name. This principal name is used as the basis for authorization which is described below. All objects in the NIS+ namespace and all entries in NIS+ tables must have an owner specified for them. This owner field always contains an NIS+ principal name.</p>
Group Names	<p>Like NIS+ principal names, NIS+ group names take the form:</p> <pre>group_name.domain</pre> <p>All objects in the NIS+ namespace and all entries in NIS+ tables may optionally have a <i>group owner</i> specified for them. This group owner field, when filled in, always contains the fully qualified NIS+ group name.</p> <p>The NIS+ client library defines several interfaces (<code>nis_groups(3NSL)</code>) for dealing with NIS+ groups. These interfaces internally map NIS+ group names into an NIS+ simple name which identifies the NIS+ group object associated with that group name. This mapping can be shown as follows:</p> <pre>group.domain -> group.groups_dir.domain</pre> <p>This mapping eliminates collisions between NIS+ group names and NIS+ directory names. For example, without this mapping, a directory with the name <i>engineering.foo.com.</i>, would make it impossible to have a group named <i>engineering.foo.com.</i>. This is due to the restriction that within the NIS+ namespace, a name unambiguously identifies a single object. With this mapping, the NIS+ <i>group</i> name <i>engineering.foo.com.</i> maps to the NIS+ <i>object</i> name <i>engineering.groups_dir.foo.com.</i></p> <p>The contents of a group object is a list of NIS+ principal names, and the names of other NIS+ groups. See <code>nis_groups(3NSL)</code> for a more complete description of their use.</p>
NIS+ SECURITY	<p>NIS+ defines a security model to control access to information managed by the service. The service defines access rights that are selectively granted to individual clients or groups of clients. Principal names and group names are used to define clients and groups of clients that may be granted or denied access to NIS+ information. These principals and groups are associated with NIS+ domains as defined below.</p> <p>The security model also uses the notion of a class of principals called <i>nobody</i>, which contains all clients, whether or not they have authenticated themselves to the service. The class <i>world</i> includes any client who has been authenticated.</p>
Directories and Domains	<p>Some directories within the NIS+ namespace are referred to as NIS+ <i>Domains</i>. Domains are those NIS+ directories that contain the subdirectories <i>groups_dir</i> and <i>org_dir</i>. Further, the subdirectory <i>org_dir</i> should contain the table named <i>cred</i>. NIS+ Group names and NIS+ Principal names <i>always</i> include the NIS+ domain name after their first label.</p>

Authentication	<p>The NIS+ name service uses Secure RPC for the integrity of the NIS+ service. This requires that users of the service and their machines must have a Secure RPC key pair associated with them. This key is initially generated with either the <code>nisaddcred(1M)</code> or <code>nisclient(1M)</code> commands and modified with the <code>chkey(1)</code> or <code>nispasswd(1)</code> commands.</p> <p>The use of Secure RPC allows private information to be stored in the name service that will not be available to untrusted machines or users on the network.</p> <p>In addition to the Secure RPC key, users need a mapping of their UID into an NIS+ principal name. This mapping is created by the system administrator using either the <code>nisclient(1M)</code> or the <code>nisaddcred(1M)</code> command.</p> <p>Users that will be using machines in several NIS+ domains must insure that they have a <i>local</i> credential entry in each of those domains. This credential should be created with the NIS+ principal name of the user in the user's "home" domain. For the purposes of NIS+ and Secure RPC, the home domain is defined to be the one where the user's Secure RPC key pair is located.</p> <p>Although extended Diffie-Hellman keys use an alternative to Secure RPC, administration is done through the same commands. See <code>nisauthconf(1M)</code>.</p>						
Authorization	<p>The NIS+ service defines four access rights that can be granted or denied to clients of the service. These rights are <i>read</i>, <i>modify</i>, <i>create</i>, and <i>destroy</i>. These rights are specified in the object structure at creation time and may be modified later with the <code>nischmod(1)</code> command. In general, the rights granted for an object apply only to that object. However, for purposes of authorization, rights granted to clients reading <i>directory</i> and <i>table</i> objects are granted to those clients for all of the objects "contained" by the parent object. This notion of containment is abstract. The objects do not actually contain other objects within them. Note that <i>group</i> objects do contain the list of principals within their definition.</p> <p>Access rights are interpreted as follows:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">read</td> <td>This right grants read access to an object. For directory and table objects, having read access on the parent object conveys read access to all of the objects that are direct children of a directory, or entries within a table.</td> </tr> <tr> <td>modify</td> <td>This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted.</td> </tr> <tr> <td>create</td> <td>This right gives a client permission to create new objects where one had not previously existed. It is only used in conjunction with directory and table objects. Having create access for a table allows a client to add additional entries to the table. Having create access for a directory allows a client to add new objects to an NIS+ directory.</td> </tr> </table>	read	This right grants read access to an object. For directory and table objects, having read access on the parent object conveys read access to all of the objects that are direct children of a directory, or entries within a table.	modify	This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted.	create	This right gives a client permission to create new objects where one had not previously existed. It is only used in conjunction with directory and table objects. Having create access for a table allows a client to add additional entries to the table. Having create access for a directory allows a client to add new objects to an NIS+ directory.
read	This right grants read access to an object. For directory and table objects, having read access on the parent object conveys read access to all of the objects that are direct children of a directory, or entries within a table.						
modify	This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted.						
create	This right gives a client permission to create new objects where one had not previously existed. It is only used in conjunction with directory and table objects. Having create access for a table allows a client to add additional entries to the table. Having create access for a directory allows a client to add new objects to an NIS+ directory.						

nis+(1)

destroy This right gives a client permission to destroy or remove an existing object or entry. When a client attempts to destroy an entry or object by removing it, the service first checks to see if the table or directory containing that object grants the client destroy access. If it does, the operation proceeds, if the containing object does not grant this right then the object itself is checked to see if it grants this right to the client. If the object grants the right, then the operation proceeds; otherwise the request is rejected.

Each of these rights may be granted to any one of four different categories.

owner A right may be granted to the *owner* of an object. The owner is the NIS+ principal identified in the owner field. The owner can be changed with the `nischown(1)` command. Note that if the owner does not have modification access rights to the object, the owner cannot change any access rights to the object, unless the owner has modification access rights to its parent object.

group owner A right may be granted to the *group owner* of an object. This grants the right to any principal that is identified as a member of the group associated with the object. The group owner may be changed with the `nischgrp(1)` command. The object owner need not be a member of this group.

world A right may be granted to everyone in the *world*. This grants the right to all clients who have authenticated themselves with the service.

nobody A right may be granted to the *nobody* principal. This has the effect of granting the right to any client that makes a request of the service, regardless of whether they are authenticated or not.

Note that for bootstrapping reasons, directory objects that are NIS+ domains, the *org_dir* subdirectory and the *cred* table within that subdirectory must have *read* access to the *nobody* principal. This makes navigation of the namespace possible when a client is in the process of locating its credentials. Granting this access does not allow the contents of other tables within *org_dir* to be read (such as the entries in the password table) unless the table itself gives "real" access rights to the *nobody* principal.

Directory Authorization

Additional capabilities are provided for granting access rights to clients for directories. These rights are contained within the *object access rights* (OAR) structure of the directory. This structure allows the NIS+ service to grant rights that are not granted by the directory object to be granted for objects contained by the directory of a specific type.

An example of this capability is a directory object which does not grant create access to all clients, but does grant create access in the OAR structure for *group* type objects to clients who are members of the NIS+ group associated with the directory. In this example the only objects that could be created as children of the directory would have to be of the type *group*.

Another example is a directory object that grants create access only to the owner of the directory, and then additionally grants create access through the OAR structure for objects of type *table*, *link*, *group*, and *private* to any member of the directory's group. This has the effect of giving nearly complete create access to the group with the exception of creating subdirectories. This restricts the creation of new NIS+ domains because creating a domain requires creating both a *groups_dir* and *org_dir* subdirectory.

Note that there is currently no command line interface to set or change the OAR of the directory object.

Table Authorization

As with directories, additional capabilities are provided for granting access to entries within tables. Rights granted to a client by the access rights field in a table object apply to the table object and all of the entry objects "contained" by that table. If an access right is not granted by the table object, it may be granted by an entry within the table. This holds for all rights except *create*.

For example, a table may not grant read access to a client performing a `nis_list(3NSL)` operation on the table. However, the access rights field of entries within that table may grant read access to the client. Note that access rights in an entry are granted to the owner and group owner of the *entry* and not the owner or group of the table. When the list operation is performed, all entries that the client has read access to are returned. Those entries that do not grant read access are not returned. If none of the entries that match the search criterion grant read access to the client making the request, no entries are returned and the result status contains the `NIS_NOTFOUND` error code.

Access rights that are granted by the rights field in an entry are granted for the entire entry. However, in the table object an additional set of access rights is maintained for each column in the table. These rights apply to the equivalent column in the entry. The rights are used to grant access when neither the table nor the entry itself grant access. The access rights in a column specification apply to the owner and group owner of the entry rather than the owner and group owner of the table object.

When a read operation is performed, if read access is not granted by the table and is not granted by the entry but *is* granted by the access rights in a column, that entry is returned with the correct values in all columns that are readable and the string `*NP*` (No Permission) in columns where read access is not granted.

As an example, consider a client that has performed a list operation on a table that does not grant read access to that client. Each entry object that satisfied the search criterion specified by the client is examined to see if it grants read access to the client. If it does, it is included in the returned result. If it does not, then each column is checked to see if it grants read access to the client. If any columns grant read access to the client, data in those columns is returned. Columns that do not grant read access have their contents replaced by the string `*NP*`. If none of the columns grant read access, then the entry is not returned.

nis+(1)

**Protocol Operation
Authorization**

Most NIS+ operations have implied access control through the permissions on the objects that they manipulate. For example, in order to read an entry in a table, you must have read permission on that entry. However, some NIS+ operations by default perform no access checking at all and so are allowed for anyone.

<i>Operation</i>	<i>Example of commands that use the operation</i>
NIS_CHECKPOINT	nisping -C
NIS_CPTIME	nisping, rpc.nisd
NIS_MKDIR	nismkdir
NIS_PING	nisping, rpc.nisd
NIS_RMDIR	nisrmdir
NIS_SERVSTATE	nisbackup, nisrestore
NIS_STATUS	nisstat, rpc.nispasswd

See `nisopaccess(1)` for a description of how to enforce access control to these NIS+ operations.

**LIST OF
COMMANDS
NIS+ User
Commands**

The following lists all commands and programming functions related to NIS+:

<code>nisaddent(1M)</code>	add /etc files and NIS maps into their corresponding NIS+ tables
<code>niscat(1)</code>	display NIS+ tables and objects
<code>nischgrp(1)</code>	change the group owner of a NIS+ object
<code>nischmod(1)</code>	change access rights on a NIS+ object
<code>nischown(1)</code>	change the owner of a NIS+ object
<code>nischttl(1)</code>	change the time to live value of a NIS+ object
<code>nisdefaults(1)</code>	display NIS+ default values
<code>niserror(1)</code>	display NIS+ error messages
<code>nisgrep(1)</code>	utilities for searching NIS+ tables
<code>nisgrpadm(1)</code>	NIS+ group administration command
<code>nisln(1)</code>	symbolically link NIS+ objects
<code>nisls(1)</code>	list the contents of a NIS+ directory
<code>nismatch(1)</code>	utilities for searching NIS+ tables
<code>nismkdir(1)</code>	create NIS+ directories
<code>nisopaccess(1)</code>	access control for protocol operations
<code>nispasswd(1)</code>	change NIS+ password information

**NIS+
Administrative
Commands**

	nis+(1)
nismrm(1)	remove NIS+ objects from the namespace
nismrmdir(1)	remove NIS+ directories
nisshowcache(1M)	NIS+ utility to print out the contents of the shared cache file
nistbladm(1)	NIS+ table administration command
nistest(1)	return the state of the NIS+ namespace using a conditional expression
aliasadm(1M)	manipulate the NIS+ aliases map
nis_cachemgr(1M)	NIS+ utility to cache location information about NIS+ servers
nisaddcred(1M)	create NIS+ credentials
nisaddent(1M)	create NIS+ tables from corresponding /etc files or NIS+ maps
nisauthconf(1M)	configure extended Diffie-Hellman keys
nisbackup(1M)	backup NIS+ directories
nisclient(1M)	initialize NIS+ credentials for NIS+ principals
nisd(1M)	NIS+ service daemon
nisd_resolv(1M)	NIS+ service daemon
nisinit(1M)	NIS+ client and server initialization utility
nislog(1M)	display the contents of the NIS+ transaction log
nisping(1M)	send ping to NIS+ servers
nispopulate(1M)	populate the NIS+ tables in a NIS+ domain
nisprefadm(1M)	NIS+ utility to set server preferences for NIS+ clients
nisrestore(1M)	restore NIS+ directory backup
nisserver(1M)	set up NIS+ servers
nissetup(1M)	initialize a NIS+ domain
nisshowcache(1M)	NIS+ utility to print out the contents of the shared cache file
nisstat(1M)	report NIS+ server statistics
nisupdkeys(1M)	update the public keys in a NIS+ directory object

nis+(1)

NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	niscat – display NIS+ tables and objects
SYNOPSIS	<p>niscat [-AhLMv] [-s <i>sep</i>] <i>tablename</i>...</p> <p>niscat [-ALMP] -o <i>name</i>...</p>
DESCRIPTION	<p>In the first synopsis, <i>niscat</i> displays the contents of the NIS+ tables named by <i>tablename</i>. In the second synopsis, it displays the internal representation of the NIS+ objects named by <i>name</i>.</p> <p>Columns without values in the table are displayed by two adjacent separator characters.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -A Display the data within the table and all of the data in tables in the initial table's concatenation path. -h Display the header line prior to displaying the table. The header consists of the '#' (hash) character followed by the name of each column. The column names are separated by the table separator character. -L Follow links. When this option is specified, if <i>tablename</i> or <i>name</i> names a LINK type object, the link is followed and the object or table named by the link is displayed. -M Master server only. This option specifies that the request should be sent to the master server of the named data. This guarantees that the most up-to-date information is seen at the possible expense of increasing the load on the master server and increasing the possibility of the NIS+ server being unavailable or busy for updates. -P Follow concatenation path. This option specifies that the request should follow the concatenation path of a table if the initial search is unsuccessful. This option is only useful when using an indexed name for <i>name</i> and the -o option. -v Display binary data directly. This option displays columns containing binary data on the standard output. Without this option binary data is displayed as the string *BINARY*. -o <i>name</i> Display the internal representation of the named NIS+ object(s). If <i>name</i> is an indexed name (see <i>nismatch(1)</i>), then each of the matching entry objects is displayed. This option is used to display access rights and other attributes of individual columns. -s <i>sep</i> This option specifies the character to use to separate the table columns. If no character is specified, the default separator for the table is used.

niscat(1)

EXAMPLES

EXAMPLE 1 Using the niscat Command

This example displays the contents of the hosts table.

```
example% niscat -h hosts.org_dir
# cname  name  addr  comment
client1  client1  129.144.201.100  Joe Smith
crunchy  crunchy  129.144.201.44   Jane Smith
crunchy  softy    129.144.201.44
```

The string *NP* is returned in those fields where the user has insufficient access rights.

Display the passwd.org_dir on the standard output.

```
example% niscat passwd.org_dir
```

Display the contents of table frodo and the contents of all tables in its concatenation path.

```
example% niscat -A frodo
```

Display the entries in the table groups.org_dir as NIS+ objects. Note that the brackets are protected from the shell by single quotes.

```
example% niscat -o '[ ]groups.org_dir'
```

Display the table object of the passwd.org_dir table.

```
example% niscat -o passwd.org_dir
```

The previous example displays the passwd table object and not the passwd table. The table object include information such as the number of columns, column type, searchable or not searchable separator, access rights, and other defaults.

Display the directory object for org_dir, which includes information such as the access rights and replica information.

```
example% niscat -o org_dir
```

ENVIRONMENT VARIABLES

NIS_PATH If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see nisdefaults(1)).

EXIT STATUS

niscat returns the following values:

0	Successful completion
1	An error occurred.

ATTRIBUTES

nischgrp(1)

NAME	nischgrp – change the group owner of a NIS+ object
SYNOPSIS	nischgrp [-AfLP] <i>group name...</i>
DESCRIPTION	<p>nischgrp changes the group owner of the NIS+ objects or entries specified by <i>name</i> to the specified NIS+ <i>group</i>. Entries are specified using indexed names (see nismatch(1)). If <i>group</i> is not a fully qualified NIS+ group name, it will be resolved using the directory search path (see nisdefaults(1)).</p> <p>The only restriction on changing an object's group owner is that you must have modify permissions for the object.</p> <p>This command will fail if the master NIS+ server is not running.</p> <p>The NIS+ server will check the validity of the group name prior to effecting the modification.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-A Modify all entries in all tables in the concatenation path that match the search criterion specified in <i>name</i>. This option implies the -P switch.-f Force the operation and fail silently if it does not succeed.-L Follow links and change the group owner of the linked object or entries rather than the group owner of the link itself.-P Follow the concatenation path within a named table. This option only makes sense when either <i>name</i> is an indexed name or the -L switch is also specified and the named object is a link pointing to entries.
EXAMPLES	<p>EXAMPLE 1 Using the nischgrp Command</p> <p>The following two examples show how to change the group owner of an object to a group in a different domain, and how to change it to a group in the local domain, respectively.</p> <pre>example% nischgrp newgroup.remote.domain. object example% nischgrp my-buds object</pre> <p>This example shows how to change the group owner for a password entry.</p> <pre>example% nischgrp admins '[uid=99],passwd.org_dir'</pre> <p>In the previous example, admins is a NIS+ group in the same domain.</p> <p>The next two examples change the group owner of the object or entries pointed to by a link, and the group owner of all entries in the hobbies table.</p> <pre>example% nischgrp -L my-buds linkname example% nischgrp my-buds '[],hobbies'</pre>

nischgrp(1)

**ENVIRONMENT
VARIABLES**

NIS_PATH

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).

EXIT STATUS

The following exit values are returned:

0 Successful operation.

1 Operation failed.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

nischmod(1)

NAME	nischmod – change access rights on a NIS+ object
SYNOPSIS	nischmod [-AfLP] <i>mode name...</i>
DESCRIPTION	<p>nischmod changes the access rights (mode) of the NIS+ objects or entries specified by <i>name</i> to <i>mode</i>. Entries are specified using indexed names (see <code>nismatch(1)</code>). Only principals with modify access to an object may change its mode.</p> <p><i>mode</i> has the following form:</p> <p><i>rights</i> [, <i>rights</i>] . . .</p> <p><i>rights</i> has the form:</p> <p>[<i>who</i>] <i>op permission</i> [<i>op permission</i>] . . .</p> <p><i>who</i> is a combination of:</p> <ul style="list-style-type: none">n Nobody's permissions.o Owner's permissions.g Group's permissions.w World's permissions.a All, or owg. <p>If <i>who</i> is omitted, the default is a.</p> <p><i>op</i> is one of:</p> <ul style="list-style-type: none">+ To grant the <i>permission</i>.- To revoke the <i>permission</i>.= To set the permissions explicitly. <p><i>permission</i> is any combination of:</p> <ul style="list-style-type: none">r Read.m Modify.c Create.d Destroy. <p>Unlike the system <code>chmod(1)</code> command, this command does not accept an octal notation.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-A Modify all entries in all tables in the concatenation path that match the search criteria specified in <i>name</i>. This option implies the -P switch.

- f Force the operation and fail silently if it does not succeed.
- L Follow links and change the permission of the linked object or entries rather than the permission of the link itself.
- P Follow the concatenation path within a named table. This option is only applicable when either *name* is an indexed name or the -L switch is also specified and the named object is a link pointing to an entry.

EXAMPLES **EXAMPLE 1** Using the `nischmod` Command

This example gives everyone read access to an object. (that is, access for owner, group, and all).

```
example% nischmod a+r object
```

This example denies create and modify privileges to group and unauthenticated clients (*nobody*).

```
example% nischmod gn-cm object
```

In this example, a complex set of permissions are set for an object.

```
example% nischmod o=rmdc,g=rm,w=rc,n=r object
```

This example sets the permissions of an entry in the password table so that the group owner can modify them.

```
example% nischmod g+m '[uid=55],passwd.org_dir'
```

The next example changes the permissions of a linked object.

```
example% nischmod -L w+mr linkname
```

ENVIRONMENT VARIABLES

NIS_PATH

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

NAME	nischown – change the owner of a NIS+ object
SYNOPSIS	nischown [-AfLP] <i>owner name...</i>
DESCRIPTION	<p>nischown changes the owner of the NIS+ objects or entries specified by <i>name</i> to <i>owner</i>. Entries are specified using indexed names (see <code>nismatch(1)</code>). If <i>owner</i> is not a fully qualified NIS+ principal name (see <code>nisaddcred(1M)</code>), the default domain (see <code>nisdefaults(1)</code>) will be appended to it.</p> <p>The only restriction on changing an object’s owner is that you must have modify permissions for the object. Note: If you are the current owner of an object and you change ownership, you may not be able to regain ownership unless you have modify access to the new object.</p> <p>The command will fail if the master NIS+ server is not running.</p> <p>The NIS+ server will check the validity of the name before making the modification.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -A Modify all entries in all tables in the concatenation path that match the search criteria specified in <i>name</i>. It implies the -P option. -f Force the operation and fail silently if it does not succeed. -L Follow links and change the owner of the linked object or entries rather than the owner of the link itself. -P Follow the concatenation path within a named table. This option is only meaningful when either <i>name</i> is an indexed name or the -L option is also specified and the named object is a link pointing to entries.
EXAMPLES	<p>EXAMPLE 1 Using the <code>nischown</code> Command</p> <p>The following two examples show how to change the owner of an object to a principal in a different domain, and to change it to a principal in the local domain, respectively.</p> <pre>example% nischown bob.remote.domain. object example% nischown skippy object</pre> <p>The next example shows how to change the owner of an entry in the <code>passwd</code> table.</p> <pre>example% nischown bob.remote.domain. '[uid=99],passwd.org_dir'</pre> <p>This example shows how to change the object or entries pointed to by a link.</p> <pre>example% nischown -L skippy linkname</pre>
ENVIRONMENT VARIABLES	<p><code>NIS_PATH</code></p> <p>If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see <code>nisdefaults(1)</code>).</p>

nischown(1)

EXIT STATUS The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

Availability	SUNWnisu

SEE ALSO `nis+(1)`, `nischgrp(1)`, `nischmod(1)`, `nischttl(1)`, `nisdefaults(1)`, `nisaddcred(1M)`, `nismatch(1)`, `nis_objects(3NSL)`, `attributes(5)`

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nischttl – change the time to live value of a NIS+ object
SYNOPSIS	nischttl [-AfLP] <i>time name...</i>
DESCRIPTION	<p>nischttl changes the time to live value (ttl) of the NIS+ objects or entries specified by <i>name</i> to <i>time</i>. Entries are specified using indexed names (see nismatch(1)).</p> <p>The time to live value is used by object caches to expire objects within their cache. When an object is read into the cache, this value is added to the current time in seconds yielding the time when the cached object would expire. The object may be returned from the cache until the current time is earlier than the calculated expiration time. When the expiration time has been reached, the object will be flushed from the cache.</p> <p>The time to live <i>time</i> may be specified in seconds or in days, hours, minutes, seconds format. The latter format uses a suffix letter of d, h, m, or s to identify the units of time. See the examples below for usage.</p> <p>The command will fail if the master NIS+ server is not running.</p> <p>Setting a high ttl value allows objects to stay persistent in caches for a longer period of time and can improve performance. However, when an object changes, in the worst case, the number of seconds in this attribute must pass before that change is visible to all clients. Setting a ttl value of 0 means that the object should not be cached at all.</p> <p>A high ttl value is a week, a low value is less than a minute. Password entries should have ttl values of about 12 hours (easily allows one password change per day), entries in the RPC table can have ttl values of several weeks (this information is effectively unchanging).</p> <p>Only directory and group objects are cached in this implementation.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -A Modify all tables in the concatenation path that match the search criterion specified in <i>name</i>. This option implies the -P switch. -f Force the operation and fail silently if it does not succeed. -L Follow links and change the time to live of the linked object or entries rather than the time to live of the link itself. -P Follow the concatenation path within a named table. This option only makes sense when either <i>name</i> is an indexed name or the -L switch is also specified and the named object is a link pointing to entries.
EXAMPLES	<p>EXAMPLE 1 Changing the ttl of an Object</p> <p>The following example shows how to change the ttl of an object using the seconds format and the days, hours, minutes, seconds format. The ttl of the second object is set to 1 day and 12 hours.</p>

nischttl(1)

EXAMPLE 1 Changing the ttl of an Object *(Continued)*

```
example% nischttl 184000 object
example% nischttl 1d12h object
```

EXAMPLE 2 Changing the ttl for a password Entry

This example shows how to change the ttl for a password entry.

```
example% nischttl 1h30m '[uid=99],passwd.org_dir'
```

EXAMPLE 3 Changing the ttl of Entries Pointed to by a Link

The next two examples change the ttl of the object or entries pointed to by a link, and the ttl of all entries in the hobbies table.

```
example% nischttl -L 12h linkname
example% nischttl 3600 '[],hobbies'
```

ENVIRONMENT VARIABLES

NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See `nisdefaults(1)`.

EXIT STATUS

The following exit values are returned:

0 Successful operation.
1 Operation failed.

ATTRIBUTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nisdefaults – display NIS+ default values
SYNOPSIS	nisdefaults [-adghprstv]
DESCRIPTION	The <code>nisdefaults</code> utility prints the default values that are returned by calls to the NIS+ local name functions (see <code>nis_local_names(3NSL)</code>). With no options specified, all defaults will be printed in a verbose format. With options, only that option is displayed in a terse form suitable for shell scripts. See the example below.
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -a Print all defaults in a terse format. -d Print the default domain name. -g Print the default group name. -h Print the default host name. -p Print the default principal name. -r Print the default access rights with which new objects will be created. -s Print the default directory search path. -t Print the default time to live value. -v Print the defaults in a verbose format. This prepends an identifying string to the output.
EXAMPLES	<p>EXAMPLE 1 Printing NIS+ defaults</p> <p>The following prints the NIS+ defaults for a root process on machine <code>example</code> in the <code>foo.bar.</code> domain:</p> <pre>example# nisdefaults Principal Name : example.foo.bar. Domain Name : foo.bar. Host Name : example.foo.bar. Group Name : Access Rights : - - - -rmcdr- - -r - - - Time to live : 12:00:00 Search Path : foo.bar.</pre> <p>EXAMPLE 2 Setting a variable in the shell script</p> <p>This example sets a variable in a shell script to the default domain:</p> <pre>DOMAIN=`nisdefaults -d`</pre> <p>EXAMPLE 3 Printing the default time to live in verbose format</p> <p>This example prints out the default time to live in a verbose format:</p>

nisdefaults(1)

EXAMPLE 3 Printing the default time to live in verbose format (Continued)

```
example% nisdefaults -tv
Time to live : 12:00:00
```

EXAMPLE 4 Printing the time to live in terse format

This example prints out the time to live in the terse format:

```
example% nisdefaults -t
43200
```

ENVIRONMENT VARIABLES

Several environment variables affect the defaults associated with a process.

NIS_DEFAULTS

This variable contains a defaults string that will override the NIS+ standard defaults. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

t_{tl}=time

This token sets the default time to live for objects that are created. The value *time* is specified in the format as defined by the `nischttl` (1) command. The default value is 12 hours.

owner=ownername

This token specifies that the NIS+ principal *ownername* should own created objects. The default for this value is the principal who is executing the command.

group=groupname

This token specifies that the group *groupname* should be the group owner for created objects. The default is NULL.

access=rights

This token specifies the set of access rights that are to be granted for created objects. The value *rights* is specified in the format as defined by the `nischmod`(1) command. The default value is:
- - - -rmcdr- - -r- - -.

NIS_GROUP

This variable contains the name of the local NIS+ group. If the name is not fully qualified, the default domain will be appended to it.

NIS_PATH

This variable overrides the default NIS+ directory search path. It contains an ordered list of directories

nisdefaults(1)

separated by ':' (colon) characters. The '\$' (dollar sign) character is treated specially. Directory names that end in '\$' have the default domain appended to them, and a '\$' by itself is replaced by the list of directories between the default domain and the global root that are at least two levels deep. The default NIS+ directory search path is '\$'.

Refer to the Name Expansion subsection in nis+(1) for more details.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

niserror(1)

NAME niserror – display NIS+ error messages

SYNOPSIS **niserror** *error-num*

DESCRIPTION niserror prints the NIS+ error associated with status value *error-num* on the standard output. It is used by shell scripts to translate NIS+ error numbers that are returned into text messages.

EXAMPLES **EXAMPLE 1** Using niserror

The following example prints the error associated with the error number 20:

```
example% niserror 20
Not Found, no such name
```

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nisgrpadm – NIS+ group administration command
SYNOPSIS	<pre> nisgrpadm -a -r -t [-s] <i>group principal...</i> nisgrpadm -d -l [-M] [-s] <i>group</i> nisgrpadm -c [-D <i>defaults</i>] [-M] [-s] <i>group</i> </pre>
DESCRIPTION	<p>The <code>nisgrpadm</code> utility is used to administer NIS+ groups. This command administers both groups and the groups' membership lists. <code>nisgrpadm</code> can create, destroy, or list NIS+ groups. <code>nisgrpadm</code> can be used to administer a group's membership list. It can add or delete principals to the group, or test principals for membership in the group.</p> <p>The names of NIS+ groups are syntactically similar to names of NIS+ objects but they occupy a separate namespace. A group named <code>a.b.c.d.</code> is represented by a NIS+ group object named <code>a.groups_dir.b.c.d.</code>; the functions described here all expect the name of the group, not the name of the corresponding group object.</p> <p>There are three types of group members:</p> <ul style="list-style-type: none"> ■ An <i>explicit</i> member is just a NIS+ principal-name. For example: <code>wickedwitch.west.oz.</code> ■ An <i>implicit</i> ("domain") member, written <code>*.west.oz.</code>, means that all principals in the given domain belong to this member. No other forms of wildcarding are allowed; <code>wickedwitch.*.oz.</code> is invalid, as is <code>wickedwitch.west.*.</code>. Note that principals in subdomains of the given domain are <i>not</i> included. ■ A <i>recursive</i> ("group") member, written <code>@cowards.oz.</code>, refers to another group; all principals that belong to that group are considered to belong here. <p>Any member may be made <i>negative</i> by prefixing it with a minus sign ('-'). A group may thus contain explicit, implicit, recursive, negative explicit, negative implicit, and negative recursive members.</p> <p>A principal is considered to belong to a group if it belongs to at least one non-negative group member of the group and belongs to no negative group members.</p> <p>Principal names <i>must</i> be fully qualified, whereas groups can be abbreviated on all operations <i>except</i> create.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Adds the list of NIS+ principals specified to <i>group</i>. The principal name should be fully qualified. -c Creates <i>group</i> in the NIS+ namespace. The NIS+ group name should be fully qualified. -d Destroys (removes) <i>group</i> from the namespace. -D <i>defaults</i> When creating objects, this option specifies a different set of defaults to be used during this operation. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the

nisgrpadm(1)

default values to be used for the generic object properties. All of the legal tokens are described below.

`tttl=time` This token sets the default time to live for objects that are created by this command. The value *time* is specified in the format as defined by the `nischttl(1)` command. The default value is 12 hours.

`owner=ownername` This token specifies that the NIS+ principal *ownername* should own the created object. Normally this value is the same as the principal who is executing the command.

`group=groupname` This token specifies that the group *groupname* should be the group owner for the object that is created. The default value is NULL.

`access=rights` This token specifies the set of access rights that are to be granted for the given object. The value *rights* is specified in the format as defined by the `nischmod(1)` command. The default value is
- - - -rmcdr- - -r- - -.

- l Lists the membership list of the specified *group*. (See -M option.)
- M Master server only. Sends the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. Note that the -M flag is applicable only with the -l flag.
- r Removes the list of principals specified from *group*. The principal name should be fully qualified.
- s Work silently. Results are returned using the exit status of the command. This status can be translated into a text string using the `niserror(1)` command.
- t Displays whether the principals specified are members in *group*.

Administering Groups

EXAMPLE 1 Creating a group

This example shows how to create a group in the `foo.com.` domain:

```
example% nisgrpadm -c my_buds.foo.com.
```

Administering Members**EXAMPLE 2** How to remove a group

This example shows how to remove the group from the current domain.

```
example% nisgrpadm -d fred's_group
```

EXAMPLE 3 Adding to the group

This example shows how one would add two principals, bob and betty, to the group my_buds.foo.com.:

```
example% nisgrpadm -a my_buds.foo.com. bob.bar.com. betty.foo.com.
```

EXAMPLE 4 How to remove a principal from the group

This example shows how to remove betty from fred's_group:

```
example% nisgrpadm -r fred's_group betty.foo.com.
```

ENVIRONMENT VARIABLES

NIS_DEFAULTS

This variable contains a defaults string that will override the NIS+ standard defaults.

NIS_PATH

If this variable is set, and the NIS+ group name is not fully qualified, each directory specified will be searched until the group is found (see nisdefaults(1)).

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

nis+(1), nischgrp(1), nischmod(1), nischttl(1), nisdefaults(1), niserror(1), nis_groups(3NSL), attributes(5)

DIAGNOSTICS

NIS_SUCCESS

On success, this command returns an exit status of 0.

NIS_PERMISSION

When you do not have the needed access right to change the group, the command returns this error.

NIS_NOTFOUND

This is returned when the group does not exist.

NIS_TRYAGAIN

This error is returned when the server for the group's domain is currently checkpointing or otherwise in a read-only state. The command should be retried at a later date.

NIS_MODERROR

This error is returned when the group was modified by someone else during the execution of the command.

nisgrpadm(1)

Reissue the command and optionally recheck the group's membership list.

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nisln – symbolically link NIS+ objects	
SYNOPSIS	nisln [-L] [-D <i>defaults</i>] <i>name linkname</i>	
DESCRIPTION	<p>The <code>nisln</code> command links a NIS+ object named <i>name</i> to a NIS+ name <i>linkname</i>. If <i>name</i> is an indexed name (see <code>nismatch(1)</code>), the link points to entries within a NIS+ table. Clients wishing to look up information in the name service can use the <code>FOLLOW_LINKS</code> flag to force the client library to follow links to the name they point to. Further, all of the NIS+ administration commands accept the <code>-L</code> switch indicating they should follow links (see <code>nis_names(3NSL)</code> for a description of the <code>FOLLOW_LINKS</code> flag).</p> <p>When creating the link, <code>nisln</code> verifies that the linked object exists. Once created, the linked object may be deleted or replaced and the link will not be affected. At that time the link will become invalid and attempts to follow it will return <code>NIS_LINKNAMEERROR</code> to the client. When the path attribute in tables specifies a link rather than another table, the link will be followed if the flag <code>FOLLOW_LINKS</code> was present in the call to <code>nis_list()</code> (see <code>nis_tables(3NSL)</code>) and ignored if the flag is not present. If the flag is present and the link is no longer valid, a warning is sent to the system logger and the link is ignored.</p>	
OPTIONS	The following options are supported:	
	<code>-L</code>	When present, this option specifies that this command should follow links. If <i>name</i> is itself a link, then this command will follow it to the linked object that it points to. The new link will point to that linked object rather than to <i>name</i> .
	<code>-D defaults</code>	Specify a different set of defaults to be used for the creation of the link object. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.
	<code>ttl=time</code>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default is 12 hours.
	<code>owner=ownername</code>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the the principal who is executing the command.
	<code>group=groupname</code>	This token specifies that the group <i>groupname</i> should be the group

nisl(1)

`access=rights`

owner for the object that is created. The default is NULL.

This token specifies the set of access rights that are to be granted for the given object. The value *rights* is specified in the format as defined by the `nischmod(1)` command. The default value is
- - - -r-mcdr- - -r- - -.

EXAMPLES

EXAMPLE 1 Creating a link

In this example we create a link in the domain `foo.com.` named `hosts` that points to the object `hosts.bar.com.:`

```
example% nisl hosts.bar.com. hosts.foo.com.
```

In this example we make a link `example.sun.com.` that points to an entry in the `hosts` table in `eng.sun.com:`

EXAMPLE 2 Making a link that points to an entry in the `hosts` table

```
example% nisl '[name=example],hosts.eng.sun.com.' example.sun.com.
```

ENVIRONMENT VARIABLES

`NIS_PATH`

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

0 Successful operation.

1 Operation failed.

NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nisl – list the contents of a NIS+ directory
SYNOPSIS	nisl [-dglLmMR] [<i>name</i> ...]
DESCRIPTION	For each <i>name</i> that is a NIS+ directory, nisl lists the contents of the directory. For each <i>name</i> that is a NIS+ object other than a directory, nisl simply echos the name. If no <i>name</i> is specified, the first directory in the search path is listed. See nisdefaults(1) .
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -d Treat NIS+ directories like other NIS+ objects, rather than listing their contents. -g Display group owner instead of owner when listing in long format. -l List in long format. This option displays additional information about the objects such as their type, creation time, owner, and access rights. The access rights are listed in the following order in long mode: nobody, owner, group owner, and world. -L This option specifies that links are to be followed. If <i>name</i> actually points to a link, it is followed to the linked object. -m Display modification time instead of creation time when listing in long format. -M Master only. This specifies that information is to be returned from the master server of the named object. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. -R List directories recursively. This option will reiterate the list for each subdirectory found in the process of listing each <i>name</i>.
ENVIRONMENT VARIABLES	NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See nisdefaults(1) .
EXIT STATUS	The following exit values are returned: <ul style="list-style-type: none"> 0 Successful operation. 1 Operation failed.
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

NOTES | NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nismatch, nisgrep – utilities for searching NIS+ tables
SYNOPSIS	<pre> nismatch [-AchMoPv] [-s <i>sep</i>] <i>key tablename</i> nismatch [-AchMoPv] [-s <i>sep</i>] <i>colname = key... tablename</i> nismatch [-AchMoPv] [-s <i>sep</i>] <i>indexedname</i> nisgrep [-AchiMov] [-s <i>sep</i>] <i>keypat tablename</i> nisgrep [-AchiMov] [-s <i>sep</i>] <i>colname = keypat... tablename</i> </pre>
DESCRIPTION	<p>The utilities <code>nismatch</code> and <code>nisgrep</code> can be used to search NIS+ tables. The command <code>nisgrep</code> differs from the <code>nismatch</code> command in its ability to accept regular expressions <i>keypat</i> for the search criteria rather than simple text matches.</p> <p>Because <code>nisgrep</code> uses a callback function, it is not constrained to searching only those columns that are specifically made searchable at the time of table creation. This makes it more flexible, but slower, than <code>nismatch</code>.</p> <p>In <code>nismatch</code>, the server does the searching, whereas in <code>nisgrep</code> the server returns all the readable entries and then the client does the pattern-matching.</p> <p>In both commands, the parameter <i>tablename</i> is the NIS+ name of the table to be searched. If only one key or key pattern is specified without the column name, then it is applied searching the first column. Specific named columns can be searched by using the <i>colname=key</i> syntax. When multiple columns are searched, only entries that match in all columns are returned. This is the equivalent of a logical join operation.</p> <p><code>nismatch</code> accepts an additional form of search criteria, <i>indexedname</i>, which is a NIS+ indexed name of the form:</p> <pre>[<i>colname=value</i>, . . .], <i>tablename</i></pre>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -A All data. Return the data within the table and all of the data in tables in the initial table's concatenation path. -c Print only a count of the number of entries that matched the search criteria. -h Display a header line before the matching entries that contains the names of the table's columns -i Ignore upper/lower case distinction during comparisons. -M Master server only. Send the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. -o Display the internal representation of the matching NIS+ object(s).

nismatch(1)

- P Follow concatenation path. Specify that the lookup should follow the concatenation path of a table if the initial search is unsuccessful.
- s *sep* This option specifies the character to use to separate the table columns. If no character is specified, the default separator for the table is used.
- v Verbose. Do not suppress the output of binary data when displaying matching entries. Without this option binary data is displayed as the string *BINARY*.

EXAMPLES

EXAMPLE 1 Searching a table for a username

This example searches a table named `passwd` in the `org_dir` subdirectory of the `zotz.com.` domain. It returns the entry that has the username of `skippy`. In this example, all the work is done on the server:

```
example% nismatch name=skippy passwd.org_dir.zotz.com.
```

EXAMPLE 2 Finding users using specific shells

This example is similar to the one above, except that it uses `nisgrep` to find all users in the table named `passwd` that are using either `ksh(1)` or `cs(1)`:

```
example% nisgrep 'shell=[ck]sh' passwd.org_dir.zotz.com.
```

ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

- 0 Successfully matches some entries.
- 1 Successfully searches the table and no matches are found.
- 2 An error condition occurs. An error message is also printed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`niscat(1)`, `nisdefaults(1)`, `nisls(1)`, `nistbladm(1)`, `nis_objects(3NSL)`, `attributes(5)`

DIAGNOSTICS

No memory
An attempt to allocate some memory for the search failed.

nismatch(1)

tablename is not a table

The object with the name *tablename* was not a table object.

Can't compile regular expression

The regular expression in *keypat* was malformed.

column not found: *colname*

The column named *colname* does not exist in the table named *tablename*.

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

nismkdir(1)

NAME	nismkdir – create NIS+ directories								
SYNOPSIS	nismkdir [-D <i>defaults</i>] [-m <i>hostname</i>] [-s <i>hostname</i>] <i>dirname</i>								
DESCRIPTION	<p>The <code>nismkdir</code> command creates new NIS+ subdirectories within an existing domain. It can also be used to create replicated directories. Without options, this command will create a subdirectory with the same master and the replicas as its parent directory.</p> <p>It is advisable to use <code>nissserver(1M)</code> to create an NIS+ domain which consists of the specified directory along with the <code>org_dir</code> and <code>groups_dir</code> subdirectories.</p> <p>The two primary aspects that are controlled when making a directory are its access rights, and its degree of replication.</p> <p>A host that serves a NIS+ directory must be a NIS+ client in a directory above the one it is serving. The exceptions to this rule are the root NIS+ servers, which are both clients and servers of the same NIS+ directory.</p> <p>When the host's default domain is different from the default domain on the client where the command is executed, the hostname supplied as an argument to the <code>-s</code> or <code>-m</code> options must be fully qualified.</p> <p>Special per-server and per-directory access restrictions may apply when this command updates the serving lists of the affected NIS+ servers. See <code>nisopaccess(1)</code>.</p>								
OPTIONS	<p>The following options are supported:</p> <table><tr><td><code>-D <i>defaults</i></code></td><td>Specify a different set of defaults to be used when creating new directories. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.</td></tr><tr><td><code>ttl=<i>time</i></code></td><td>This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default value is 12h (12 hours).</td></tr><tr><td><code>owner=<i>ownername</i></code></td><td>This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.</td></tr><tr><td><code>group=<i>groupname</i></code></td><td>This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.</td></tr></table>	<code>-D <i>defaults</i></code>	Specify a different set of defaults to be used when creating new directories. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.	<code>ttl=<i>time</i></code>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default value is 12h (12 hours).	<code>owner=<i>ownername</i></code>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.	<code>group=<i>groupname</i></code>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.
<code>-D <i>defaults</i></code>	Specify a different set of defaults to be used when creating new directories. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.								
<code>ttl=<i>time</i></code>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default value is 12h (12 hours).								
<code>owner=<i>ownername</i></code>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.								
<code>group=<i>groupname</i></code>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.								

`access=rights`

This token specifies the set of access rights that are to be granted for the given object. The value *rights* is specified in the format as defined by the `nischmod(1)` command. The default value is

```
-- -- -rmcdr- - -r- - -.
```

`-m hostname`

If the directory named by *dirname* does not exist, then a new directory that is *not* replicated is created with host *hostname* as its master server.

If the directory name by *dirname* does exist, then the host named by *hostname* is made its master server.

`-s hostname`

Specify that the host *hostname* will be a replica for an existing directory named *dirname*.

OPERANDS The following operand is supported:

dirname

The fully qualified NIS+ name of the directory that has to be created.

EXAMPLES **EXAMPLE 1** Using the `nismkdir` Command

To create a new directory `bar.foo.com.` under the `foo.com.` domain that shares the same master and replicas as the `foo.com.` directory one would use the command:

```
example% nismkdir bar.foo.com.
```

To create a new directory `bar.foo.com.` that is not replicated under the `foo.com.` domain one would use the command:

```
example% nismkdir -m myhost.foo.com. bar.foo.com.
```

To add a replica server of the `bar.foo.com.` directory, one would use the command:

```
example% nismkdir -s replica.foo.com. bar.foo.com.
```

ENVIRONMENT VARIABLES

`NIS_DEFAULTS`

This variable contains a defaults string that will override the NIS+ standard defaults. If the `-D` switch is used those values will then override both the `NIS_DEFAULTS` variable and the standard defaults.

`NIS_PATH`

If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see `nisdefaults(1)`).

EXIT STATUS The following exit values are returned:

nismkdir(1)

- 0 Successful operation.
- 1 Operation failed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nisopaccess – NIS+ operation access control administration command																		
SYNOPSIS	<p>nisopaccess [-v] <i>directory operation rights</i></p> <p>nisopaccess [-v] [-r] <i>directory operation</i></p> <p>nisopaccess [-v] [-l] <i>directory [operation]</i></p>																		
DESCRIPTION	<p>Most NIS+ operations have implied access control through the permissions on the objects that they manipulate. For example, in order to read an entry in a table, you must have read permission on that entry. However, some NIS+ operations by default perform no access checking at all and are allowed to all:</p> <table border="0" style="margin-left: 20px;"> <thead> <tr> <th style="text-align: left;"><i>Operation</i></th> <th style="text-align: left;"><i>Example of commands that use the operation</i></th> </tr> </thead> <tbody> <tr> <td>NIS_CHECKPOINT</td> <td>nisping -C</td> </tr> <tr> <td>NIS_CPTIME</td> <td>nisping, rpc.nisd</td> </tr> <tr> <td>NIS_MKDIR</td> <td>nismkdir</td> </tr> <tr> <td>NIS_PING</td> <td>nisping, rpc.nisd</td> </tr> <tr> <td>NIS_RMDIR</td> <td>nisrmdir</td> </tr> <tr> <td>NIS_SERVSTATE</td> <td>nisbackup, nisrestore</td> </tr> <tr> <td>NIS_STATUS</td> <td>nisstat, rpc.nispasswd</td> </tr> </tbody> </table> <p>The <code>nisopaccess</code> command can be used to enforce access control on these operations on a per NIS+ directory basis.</p> <p>The <i>directory</i> argument should be the fully qualified name, including the trailing dot, of the NIS+ directory to which <code>nisopaccess</code> will be applied. As a short-hand, if the directory name does not end in a trailing dot, for example “org_dir”, then the domain name is appended. The domain name is also appended to partial paths such as “org_dir.xyz”.</p> <p>You can use upper or lower case for the <i>operation</i> argument; however, you cannot mix cases. The “NIS_” prefix may be omitted. For example, NIS_PING can be specified as NIS_PING, nis_ping, PING, or ping.</p> <p>The <i>rights</i> argument is specified in the format defined by the <code>nischmod(1)</code> command. Since only the read (“r”) rights are used to determine who has the right to perform the operation, the modify and delete rights may be used to control who can change access to the operation.</p> <p>The access checking performed for each operation is as follows. When an operation requires access be checked on all directories served by its <code>rpc.nisd(1M)</code>, access is denied if even one of the directories prohibits the operation.</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="vertical-align: top;">NIS_CHECKPOINT</td> <td>Check specified directory, or all directories if there is no directory argument (as is the case when NIS_CHECKPOINT is</td> </tr> </table>	<i>Operation</i>	<i>Example of commands that use the operation</i>	NIS_CHECKPOINT	nisping -C	NIS_CPTIME	nisping, rpc.nisd	NIS_MKDIR	nismkdir	NIS_PING	nisping, rpc.nisd	NIS_RMDIR	nisrmdir	NIS_SERVSTATE	nisbackup, nisrestore	NIS_STATUS	nisstat, rpc.nispasswd	NIS_CHECKPOINT	Check specified directory, or all directories if there is no directory argument (as is the case when NIS_CHECKPOINT is
<i>Operation</i>	<i>Example of commands that use the operation</i>																		
NIS_CHECKPOINT	nisping -C																		
NIS_CPTIME	nisping, rpc.nisd																		
NIS_MKDIR	nismkdir																		
NIS_PING	nisping, rpc.nisd																		
NIS_RMDIR	nisrmdir																		
NIS_SERVSTATE	nisbackup, nisrestore																		
NIS_STATUS	nisstat, rpc.nispasswd																		
NIS_CHECKPOINT	Check specified directory, or all directories if there is no directory argument (as is the case when NIS_CHECKPOINT is																		

nisopaccess(1)

	issued by the "nisping -Ca" command).. Return NIS_PERMISSION when access is denied.
NIS_CPTIME	Check specified directory. It returns 0 when access is denied.
NIS_MKDIR	Check parent of specified directory. Returns NIS_PERMISSION when access is denied. If the parent directory is not available locally, that is, it is not served by this <code>rpc.nisd(1M)</code> , NIS_MKDIR access is allowed, though the operation will be executed only if this <code>rpc.nisd</code> is a known replica of the directory. You should note that the NIS_MKDIR operation does not create a NIS+ directory; it adds a directory to the serving list for this <code>rpc.nisd</code> , if appropriate.
NIS_PING	Check specified directory. No return value.
NIS_RMDIR	Check specified directory. NIS_PERMISSION is returned when access denied. The NIS_RMDIR operation does not remove a NIS+ directory; it deletes the directory from the serving list for this <code>rpc.nisd</code> , if appropriate.
NIS_SERVSTATE	Check access on all directories served by this <code>rpc.nisd</code> . If access is denied for a tag, "<permission denied>" is returned instead of the tag value.
NIS_STATUS	Same as for NIS_SERVSTATE.

Note that older clients may not supply authentication information for some of the operations listed above. These clients are treated as "nobody" when access checking is performed.

The access control is implemented by creating a NIS+ table called "proto_op_access" in each NIS+ directory to which access control should be applied. The table can be manipulated using normal NIS+ commands. However, `nisopaccess` is the only supported interface for NIS+ operation access control.

OPTIONS

The following options are supported:

-l	List the access control for a single operation, or for all operations that have access control enabled.
-r	Remove access control for a certain operation on the specified directory.
-v	Verbose mode.

EXAMPLES**EXAMPLE 1** Enabling Access Control for the NIS_PING Operation

To enable access control for the NIS_PING operation on "org_dir.`domainname`." such that only the owner of the directory can perform a NIS_PING, or change the NIS_PING rights:

```
example% nisopaccess org_dir NIS_PING o=rmcd,g=,w=,n=
```

EXAMPLE 2 Listing the Access to NIS_PING

To list the access to the NIS_PING operation for org_dir:

```
example% nisopaccess -l org_dir NIS_PING
```

```
NIS_PING  ----rmcd-----  owner.dom.ain.  group.dom.ain.
```

EXAMPLE 3 Removing Access Control for NIS_PING

To remove access control for NIS_PING on org_dir:

```
example% nisopaccess -r org_dir NIS_PING
```

EXIT STATUS

The following exit values are returned:

0	Successful operation.
other	Operation failed. The status is usually the return status from a NIS+ command such as nistbladm.

nispasswd(1)

NAME	nispasswd – change NIS+ password information
SYNOPSIS	<pre>nispasswd [-ghs] [-D domainname] [username] nispasswd -a nispasswd [-D domainname] [-d [username]] nispasswd [-l] [-f] [-n min] [-x max] [-w warn] [-D domainname] username</pre>
DESCRIPTION	<p>The <code>nispasswd</code> utility changes a password, <code>gecos</code> (<code>finger</code>) field (<code>-g</code> option), home directory (<code>-h</code> option), or login shell (<code>-s</code> option) associated with the <code>username</code> (invoker by default) in the NIS+ <code>passwd</code> table.</p> <p>Additionally, the command can be used to view or modify aging information associated with the user specified if the invoker has the right NIS+ privileges.</p> <p><code>nispasswd</code> uses secure RPC to communicate with the NIS+ server, and therefore, never sends unencrypted passwords over the communication medium.</p> <p><code>nispasswd</code> does not read or modify the local password information stored in the <code>/etc/passwd</code> and <code>/etc/shadow</code> files.</p> <p>When used to change a password, <code>nispasswd</code> prompts non-privileged users for their old password. It then prompts for the new password twice to forestall typing mistakes. When the old password is entered, <code>nispasswd</code> checks to see if it has “aged” sufficiently. If “aging” is insufficient, <code>nispasswd</code> terminates; see <code>getspnam(3C)</code>.</p> <p>The old password is used to decrypt the username’s secret key. If the password does not decrypt the secret key, <code>nispasswd</code> prompts for the old secure-RPC password. It uses this password to decrypt the secret key. If this fails, it gives the user one more chance. The old password is also used to ensure that the new password differs from the old by at least three characters. Assuming aging is sufficient, a check is made to ensure that the new password meets construction requirements described below. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated twice. The new password is used to re-encrypt the user’s secret key. Hence, it also becomes their secure-RPC password. Therefore, the secure-RPC password is no longer a different password from the user’s password.</p> <p>Passwords must be constructed to meet the following requirements:</p> <ul style="list-style-type: none">■ Each password must have at least six characters. Only the first eight characters are significant.■ Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, “alphabetic” refers to all upper or lower case letters.■ Each password must differ from the user’s login <code>username</code> and any reverse or circular shift of that login <code>username</code>. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

- New passwords must differ from the old by at least three characters. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

Network administrators, who own the NIS+ password table, may change any password attributes if they establish their credentials (see `keylogin(1)`) before invoking `nispasswd`. Hence, `nispasswd` does not prompt these privileged-users for the old password and they are not forced to comply with password aging and password construction requirements.

Any user may use the `-d` option to display password attributes for his or her own login name. The format of the display will be:

```
username status mm/dd/yy min max warn
```

or, if password aging information is not present,

```
username status
```

where

<i>username</i>	The login ID of the user.
<i>status</i>	The password status of <i>username</i> : "PS" stands for password exists or locked, "LK" stands for locked, and "NP" stands for no password.
<i>mm/dd/yy</i>	The date password was last changed for <i>username</i> . (Note that all password aging dates are determined using Greenwich Mean Time (Universal Time) and, therefore, may differ by as much as a day in other time zones.)
<i>min</i>	The minimum number of days required between password changes for <i>username</i> .
<i>max</i>	The maximum number of days the password is valid for <i>username</i> .
<i>warn</i>	The number of days relative to <i>max</i> before the password expires that the <i>username</i> will be warned.

The use of `nispasswd` is strongly discouraged. It is a wrapper around the `passwd(1)` command.

Using `passwd(1)` with the `-r nisplus` option will achieve the same result and will be consistent across all the different name services available. This is the recommended way to change the password in NIS+.

The login program, file access display programs (for example, `ls -l`), and network programs that require user passwords, for example, `rlogin(1)`, `ftp(1)`, and so on, use the standard `getpwnam(3C)` and `getspnam(3C)` interfaces to get password information. These programs will get the NIS+ password information, which is modified by `nispasswd`, only if the `passwd:` entry in the `/etc/nsswitch.conf` file includes `nisplus`. See `nsswitch.conf(4)` for more details.

nispasswd(1)

OPTIONS

The following options are supported:

- a Shows the password attributes for all entries. This will show only the entries in the NIS+ passwd table in the local domain that the invoker is authorized to "read".
- d [*username*] Displays password attributes for the caller or the user specified if the invoker has the right privileges.
- D *domainname* Consults the `passwd.org_dir` table in *domainname*. If this option is not specified, the default *domainname* returned by `nis_local_directory()` will be used. This *domainname* is the same as that returned by `domainname(1M)`.
- f Forces the user to change password at the next login by expiring the password for *username*.
- g Changes the `gecos` (finger) information.
- h Changes the home directory.
- l Locks the password entry for *username*. Subsequently, `login(1)` would disallow logins with this NIS+ password entry.
- n *min* Sets minimum field for *username*. The *min* field contains the minimum number of days between password changes for *username*. If *min* is greater than *max*, the user may not change the password. Always use this option with the `-x` option, unless *max* is set to `-1` (aging turned off). In that case, *min* need not be set.
- s Changes the login shell. By default, only the NIS+ administrator can change the login shell. The user will be prompted for the new login shell.
- w *warn* Sets *warn* field for *username*. The *warn* field contains the number of days before the password expires that the user will be warned whenever he or she attempts to login.
- x *max* Sets maximum field for *username*. The *max* field contains the number of days that the password is valid for *username*. The aging for *username* will be turned off immediately if *max* is set to `-1`. If it is set to `0`, then the user is forced to change the password at the next login session and aging is turned off.

EXIT STATUS

The following exit values are returned:

- 0 Success.
- 1 Permission denied.
- 2 Invalid combination of options.
- 3 Unexpected failure. NIS+ passwd table unchanged.
- 4 NIS+ passwd table missing.

- 5 NIS+ is busy. Try again later.
- 6 Invalid argument to option.
- 7 Aging is disabled.
- 8 No memory.
- 9 System error.
- 10 Account expired.

nisrm(1)

NAME nisrm – remove NIS+ objects from the namespace

SYNOPSIS **nisrm** [-if] *name*...

DESCRIPTION The **nisrm** command removes NIS+ objects named *name* from the NIS+ namespace. This command will fail if the NIS+ master server is not running. This command will not remove directories. See **nisrmdir(1)**. Nor will it remove non-empty tables. See **nistbladm(1)**.

OPTIONS The following options are supported:

- i Interactive mode. Like the system **rm(1)** command the **nisrm** command will ask for confirmation prior to removing an object. If the name specified by *name* is a non-fully qualified name this option is forced on. This prevents the removal of unexpected objects.
- f Force. The removal is attempted, and if it fails for permission reasons, a **nischmod(1)** is attempted and the removal retried. If the command fails, it fails silently.

OPERANDS The following operand is supported:

name A NIS+ named object.

EXAMPLES **EXAMPLE 1** Using the **nisrm** Command

Remove the objects *foo*, *bar*, and *baz* from the namespace:

```
example% nisrm foo bar baz
```

ENVIRONMENT VARIABLES **NIS_PATH** If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See **nisdefaults(1)**.

EXIT STATUS The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO **nis+(1)**, **nischmod(1)**, **nisdefaults(1)**, **nisrmdir(1)**, **nistbladm(1)**, **rm(1)**, **attributes(5)**

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

nisrmdir(1)

NAME	<code>nisrmdir</code> – remove NIS+ directories
SYNOPSIS	<code>nisrmdir</code> [-if] [-s <i>hostname</i>] <i>dirname</i>
DESCRIPTION	<p><code>nisrmdir</code> deletes existing NIS+ subdirectories. It can remove a directory outright, or simply remove replicas from serving a directory.</p> <p>This command modifies the object that describes the directory <i>dirname</i>, and then notifies each replica to remove the directory named <i>dirname</i>. If the notification of any of the affected replicas fails, the directory object is returned to its original state unless the <code>-f</code> option is present.</p> <p>This command will fail if the NIS+ master server is not running.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-i</code> Interactive mode. Like the system <code>rm(1)</code> command the <code>nisrmdir</code> command will ask for confirmation prior to removing a directory. If the name specified by <i>dirname</i> is a non-fully qualified name this option is forced on. This prevents the removal of unexpected directories.<code>-f</code> Force the command to succeed even though it may not be able to contact the affected replicas. This option should be used when a replica is known to be down and will not be able to respond to the removal notification. When the replica is finally rebooted it will read the updated directory object, note that it is no longer a replica for that directory, and stop responding to lookups on that directory. Cleanup of the files that held the now removed directory can be accomplished manually by removing the appropriate files in the <code>/var/nis</code> directory. See <code>nisfiles(4)</code> for more information.<code>-s <i>hostname</i></code> Specify that the host <i>hostname</i> should be removed as a replica for the directory named <i>dirname</i>. If this option is not present <i>all</i> replicas and the master server for a directory are removed and the directory is removed from the namespace. <p>Special per-server and per-directory access restrictions may apply when this command updates the serving lists of the affected NIS+ servers. For more information, see <code>nisopaccess(1)</code>.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>dirname</i> An existing NIS+ directory.</p>
EXAMPLES	<p>EXAMPLE 1 Using the <code>nisrmdir</code> Command</p> <p>To remove a directory <code>bar</code> under the <code>foo.com.</code> domain, one would use the command:</p> <pre>example% nisrmdir bar.foo.com.</pre>

EXAMPLE 1 Using the `nismkdir` Command (Continued)

To remove a replica that is serving directory `bar.foo.com`, one would use the command:

```
example% nismkdir -s replica.foo.com bar.foo.com.
```

To force the removal of directory `bar.foo.com` from the namespace, one would use the command:

```
example% nismkdir -f bar.foo.com.
```

ENVIRONMENT VARIABLES

NIS_PATH If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found. See `nisdefaults(1)`.

EXIT STATUS

The following exit values are returned:

0 Successful operation.

1 Operation failed.

ATTRIBUTES

NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

nistbladm(1)

NAME	nistbladm – NIS+ table administration command
SYNOPSIS	<pre>nistbladm -a -A [-D defaults] colname = value... tablename nistbladm -a -A [-D defaults] indexedname nistbladm -c [-D defaults] [-p path] [-s sep] type colname = [flags] [, access...] tablename nistbladm -d tablename nistbladm -e -E colname = value... indexedname nistbladm -m colname = value... indexedname nistbladm -r -R [colname = value...] tablename nistbladm -r -R indexedname nistbladm -u [-p path] [-s sep] [-t type] [colname = access...] tablename</pre>
DESCRIPTION	<p>The <code>nistbladm</code> command is used to administer NIS+ tables. There are five primary operations that it performs: creating and deleting tables, adding entries to, modifying entries within, and removing entries from tables.</p> <p>Though NIS+ does not place restrictions on the size of tables or entries, the size of data has an impact on the performance and the disk space requirements of the NIS+ server. NIS+ is not designed to store huge pieces of data, such as files; instead, pointers to files should be stored in NIS+.</p> <p>NIS+ design is optimized to support 10,000 objects with a total size of 10M bytes. If the requirements exceed the above, it is suggested that the domain hierarchy be created, or the data stored in the tables be pointers to the actual data, instead of the data itself.</p> <p>When creating tables, a table type, <code>type</code>, and a list of column definitions must be provided.</p> <p><code>type</code> is a string that is stored in the table and later used by the service to verify that entries being added to it are of the correct type.</p> <p>Syntax for column definitions is:</p> <pre>colname=[flags][,access]</pre> <p><code>flags</code> is a combination of:</p> <ul style="list-style-type: none">S Searchable. Specifies that searches can be done on the column's values (see <code>nismatch(1)</code>).I Case-insensitive (only makes sense in combination with S). Specifies that searches should ignore case.C Crypt. Specifies that the column's values should be encrypted.

B Binary data (does not make sense in combination with *S*). If not set, the column's values are expected to be null terminated ASCII strings.

X XDR encoded data (only makes sense in combination with *B*).

access is specified in the format as defined by the `nischmod(1)` command.

When manipulating entries, this command takes two forms of entry name. The first uses a series of space separated *colname=value* pairs that specify column values in the entry. The second is a NIS+ indexed name, *indexedname*, of the form:

```
[ colname=value, . . . ],tablename
```

OPTIONS

The following options are supported:

-a | A Adds entries to a NIS+ table. The difference between the lowercase 'a' and the uppercase 'A' is in the treatment of preexisting entries. The entry's contents are specified by the *column=value* pairs on the command line. Values for all columns must be specified when adding entries to a table.

Normally, NIS+ reports an error if an attempt is made to add an entry to a table that would overwrite an entry that already exists. This prevents multiple parties from adding duplicate entries and having one of them get overwritten. If you wish to force the add, the uppercase 'A' specifies that the entry is to be added, even if it already exists. This is analogous to a modify operation on the entry.

-c Creates a table named *tablename* in the namespace. The table that is created must have at least one column and at least one column must be searchable.

-d *tablename* Destroys the table named *tablename*. The table that is being destroyed must be empty. The table's contents can be deleted with the `-R` option below.

-e |E Edits the entry in the table that is specified by *indexedname*. *indexedname* must uniquely identify a single entry. It is possible to edit the value in a column that would change the indexed name of an entry.

The change (*colname=value*) may affect other entries in the table if the change results in an entry whose indexed name is different from *indexedname* and which matches that of another existing entry. In this case, the `-e` option will fail and an error will be reported. The `-E` option will force the replacement of the existing entry by the new entry (effectively removing two old entries and adding a new one).

nistbladm(1)

-m	A synonym for -E. This option has been superseded by the -E option.								
-r R	Removes entries from a table. The xentry is specified by either a series of <i>column=value</i> pairs on the command line, or an indexed name that is specified as <i>entryname</i> . The difference between the interpretation of the lowercase 'r' versus the uppercase 'R' is in the treatment of non-unique entry specifications. Normally the NIS+ server will disallow an attempt to remove an entry when the search criterion specified for that entry resolves to more than one entry in the table. However, it is sometimes desirable to remove more than one entry, as when you are attempting to remove all of the entries from a table. In this case, using the uppercase 'R' will force the NIS+ server to remove all entries matching the passed search criterion. If that criterion is null and no column values specified, then all entries in the table will be removed.								
-u	Updates attributes of a table. This allows the concatenation path (-p), separation character (specified with the (-s)), column access rights, and table type string (-t) of a table to be changed. Neither the number of columns, nor the columns that are searchable may be changed.								
-D <i>defaults</i>	When creating objects, this option specifies a different set of defaults to be used during this operation. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below. <table><tr><td><i>t</i>tl=<i>time</i></td><td>This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default value is 12 hours.</td></tr><tr><td><i>owner</i>=<i>ownername</i></td><td>This token specifies that the NIS+ principal <i>ownername</i> should own the created object. Normally this value is the same as the principal who is executing the command.</td></tr><tr><td><i>group</i>=<i>groupname</i></td><td>This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.</td></tr><tr><td><i>access</i>=<i>rights</i></td><td>This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is</td></tr></table>	<i>t</i> tl= <i>time</i>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default value is 12 hours.	<i>owner</i> = <i>ownername</i>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. Normally this value is the same as the principal who is executing the command.	<i>group</i> = <i>groupname</i>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.	<i>access</i> = <i>rights</i>	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is
<i>t</i> tl= <i>time</i>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default value is 12 hours.								
<i>owner</i> = <i>ownername</i>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. Normally this value is the same as the principal who is executing the command.								
<i>group</i> = <i>groupname</i>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.								
<i>access</i> = <i>rights</i>	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is								

nistbladm(1)

specified in the format as defined by the `nischmod(1)` command. The default value is

`- - - -rmcdr- - -r- - -`.

- `-p path` When creating or updating a table, this option specifies the table's search path. When a `nis_list()` function is invoked, the user can specify the flag `FOLLOW_PATH` to tell the client library to continue searching tables in the table's path if the search criteria used does not yield any entries. The path consists of an ordered list of table names, separated by colons. The names in the path must be fully qualified.
- `-s sep` When creating or updating a table, this option specifies the table's separator character. The separator character is used by `niscat(1)` when displaying tables on the standard output. Its purpose is to separate column data when the table is in ASCII form. The default value is a space.
- `-t type` When updating a table, this option specifies the table's type string.

EXAMPLES

EXAMPLE 1 Creating an Unmodifiable Table

This example creates a table named `hobbies` in the directory `foo.com`. of the type `hobby_tbl` with two searchable columns, `name` and `hobby`.

```
example% nistbladm -c hobby_tbl name=S,\
             a+r,o+m hobby=S,a+r hobbies.foo.com.
```

The column `name` has read access for all (that is, owner, group, and world) and modify access for only the owner. The column `hobby` is readable by all, but not modifiable by anyone.

In this example, if the access rights had not been specified, the table's access rights would have come from either the standard defaults or the `NIS_DEFAULTS` variable (see below).

EXAMPLE 2 Adding Entries to the Table

To add entries to this table:

```
example% nistbladm -a name=bob hobby=skiing hobbies.foo.com.
example% nistbladm -a name=sue hobby=skiing hobbies.foo.com.
example% nistbladm -a name=ted hobby=swimming hobbies.foo.com.
```

EXAMPLE 3 Adding the Concatenation Path

In the following example, the common root domain is `foo.com` (NIS+ requires at least two components to define the root domain) and the concatenation path for the subdomains `bar` and `baz` are added:

nistbladm(1)

EXAMPLE 3 Adding the Concatenation Path (Continued)

```
example% nistbladm -u -p hobbies.bar.foo.com.:hobbies.baz.foo.com. hobbies
```

EXAMPLE 4 Deleting Skiers from the List

To delete the skiers from our list:

```
example% nistbladm -R hobby=skiing hobbies.foo.com.
```

Note: The use of the `-r` option would fail because there are two entries with the value of `skiing`.

EXAMPLE 5 Naming a Column with no Flags Set

To create a table with a column that is named with no flags set, you supply only the name and the equals (=) sign as follows:

```
example% nistbladm -c notes_tbl name=S,a+r,o+m note= notes.foo.com.
```

This example created a table, named `notes.foo.com.`, of type `notes_tbl` with two columns `name` and `note`. The `note` column is not searchable.

EXAMPLE 6 Protecting Terminal Characters

When entering data for columns in the form of a *value* string, it is essential that terminal characters be protected by single or double quotes. These are the characters equals (=), comma (,), left bracket ([), right bracket (]), and space (). These characters are parsed by NIS+ within an indexed name. These characters are protected by enclosing the entire value in double quote (") characters as follows:

```
example% nistbladm -a fullname="Joe User" nickname=Joe nicknames
```

If there is any doubt about how the string will be parsed, it is better to enclose it in quotes.

**ENVIRONMENT
VARIABLES**

NIS_DEFAULTS

This variable contains a defaults string that will be override the NIS+ standard defaults. If the `-D` switch is used those values will then override both the `NIS_DEFAULTS` variable and the standard defaults.

NIS_PATH

If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found. See `nisdefaults(1)`.

EXIT STATUS

The following exit values are returned:

0 Successful operation.

1 Operation failed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO `nis+(1)`, `niscat(1)`, `nischmod(1)`, `nischown(1)`, `nischttl(1)`, `nisdefaults(1)`, `nismatch(1)`, `nissetup(1M)`, `attributes(5)`

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

WARNINGS To modify one of the entries, say, for example, from “bob” to “robert”:

```
example% nistbladm -m name=robert [name=bob],hobbies
```

Notice that “[name=bob],hobbies” is an indexed name, and that the characters ‘[’ (open bracket) and ‘]’ (close bracket) are interpreted by the shell. When typing entry names in the form of NIS+ indexed names, the name must be protected by using single quotes.

It is possible to specify a set of defaults such that you cannot read or modify the table object later.

nistest(1)

NAME	nistest – return the state of the NIS+ namespace using a conditional expression
SYNOPSIS	nistest [-ALMP] [-a <i>rights</i> -t <i>type</i>] <i>object</i> nistest [-ALMP] [-a <i>rights</i>] <i>indexedname</i> nistest -c <i>dir1 op dir2</i>
DESCRIPTION	nistest provides a way for shell scripts and other programs to test for the existence, type, and access rights of objects and entries. Entries are named using indexed names. See nismatch(1). With the -c option, directory names can be compared to test where they lie in relation to each other in the namespace.
OPTIONS	The following options are supported: -a <i>rights</i> This option is used to verify that the current process has the desired or required access rights on the named object or entries. The access rights are specified in the same way as the nischmod(1) command. -A All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned. This option is only valid when using indexed names or following links. -L Follow links. If the object named by <i>object</i> or the tablename component of <i>indexedname</i> names a LINK type object, the link is followed when this switch is present. -M Master server only. This option specifies that the lookup should be sent to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. -P Follow concatenation path. This option specifies that the lookup should follow the concatenation path of a table if the initial search is unsuccessful. This option is only valid when using indexed names or following links. -t <i>type</i> This option tests the type of <i>object</i> . The value of <i>type</i> can be one of the following: D Return true if the object is a directory object. G Return true if the object is a group object. L Return true if the object is a link object. P Return true if the object is a private object. T Return true if the object is a table object. -c Test whether or not two directory names have a certain relationship to each other, for example, higher than (ht) or lower than (lt). The complete list of values for <i>op</i> can be displayed by

using the `-c` option with no arguments.

EXAMPLES **EXAMPLE 1** Using the `nistest` Command

When testing for access rights, `nistest` returns success (0) if the specified rights are granted to the current user. Thus, testing for access rights:

```
example% nistest -a w=mr skippy.domain
```

Tests that all authenticated NIS+ clients have read and modify access to the object named `skippy.domain`.

Testing for access on a particular entry in a table can be accomplished using the indexed name syntax. The following example tests to see if an entry in the password table can be modified:

```
example% nistest -a o=m '[uid=99],passwd.org_dir'
```

To test if a directory lies higher in the namespace than another directory, use the `-c` option with an *op* of `ht` (higher than) as in the following example (which would return true):

```
example% nistest -c dom.com. ht lower.dom.com.
```

ENVIRONMENT VARIABLES

`NIS_PATH`

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See `nisdefaults(1)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Failure due to object not present, not of specified type, and/or no such access.
- 2 Failure due to illegal usage.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`nis+(1)`, `nischmod(1)`, `nisdefaults(1)`, `nismatch(1)`, `attributes(5)`

NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

nl(1)

NAME	nl – line numbering filter								
SYNOPSIS	<pre>/usr/bin/nl [-p] [-b <i>type</i>] [-d <i>delim</i>] [-f <i>type</i>] [-h <i>type</i>] [-i [<i>incr</i>] [-l <i>num</i>] [-n <i>format</i>] [-s <i>sep</i>] [-w <i>width</i>] [-v [<i>startnum</i>]] [<i>file</i>]</pre> <pre>/usr/xpg4/bin/nl [-p] [-b <i>type</i>] [-d <i>delim</i>] [-f <i>type</i>] [-h <i>type</i>] [-i <i>incr</i>] [-l <i>num</i>] [-n <i>format</i>] [-s <i>sep</i>] [-w <i>width</i>] [-v <i>startnum</i>] [<i>file</i>]</pre>								
DESCRIPTION	<p>The nl utility reads lines from the named <i>file</i>, or the standard input if no <i>file</i> is named, and reproduces the lines on the standard output. Lines are numbered on the left in accordance with the command options in effect.</p> <p>nl views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer. For example, -bt (the default) numbers non-blank lines in the body section and does not number any lines in the header and footer sections.</p> <p>The start of logical page sections are signaled by input lines containing nothing but the following delimiter character(s):</p> <table border="1"><thead><tr><th>Line contents</th><th>Start Of</th></tr></thead><tbody><tr><td>\\:\\:</td><td>header</td></tr><tr><td>\\:</td><td>body</td></tr><tr><td>\\:</td><td>footer</td></tr></tbody></table> <p>Unless optioned otherwise, nl assumes the text being read is in a single logical page body.</p>	Line contents	Start Of	\\:\\:	header	\\:	body	\\:	footer
Line contents	Start Of								
\\:\\:	header								
\\:	body								
\\:	footer								
OPTIONS	<p>Command options may appear in any order and may be intermingled with an optional file name. Only one file may be named. The specified default is used when the option is not entered on the command line. /usr/xpg4/bin/nl options require option arguments. A SPACE character <i>may</i> separate options from option arguments. /usr/bin/nl options <i>may</i> have option arguments. If option-arguments of /usr/bin/nl options are not specified, these options result in the default. The supported options are:</p> <table><tr><td>-b<i>type</i></td><td>Specifies which logical page body lines are to be numbered. Recognized <i>types</i> and their meanings are:</td></tr><tr><td>a</td><td>number all lines</td></tr><tr><td>t</td><td>number all non-empty lines.</td></tr><tr><td>n</td><td>no line numbering</td></tr></table>	-b <i>type</i>	Specifies which logical page body lines are to be numbered. Recognized <i>types</i> and their meanings are:	a	number all lines	t	number all non-empty lines.	n	no line numbering
-b <i>type</i>	Specifies which logical page body lines are to be numbered. Recognized <i>types</i> and their meanings are:								
a	number all lines								
t	number all non-empty lines.								
n	no line numbering								

	<i>pexp</i>	number only lines that contain the regular expression specified in <i>exp</i> . See NOTES below.
		Default <i>type</i> for logical page body is <i>t</i> (text lines numbered).
- <i>f</i>	<i>type</i>	Same as <i>-btype</i> except for footer. Default <i>type</i> for logical page footer is <i>n</i> (no lines numbered).
- <i>d</i>	<i>delim</i>	The two delimiter characters specifying the start of a logical page section may be changed from the default characters (<i>\ :</i>) to two user-specified characters. If only one character is entered, the second character remains the default character (<i>:</i>). No space should appear between the <i>-d</i> and the delimiter characters. To enter a backslash, use two backslashes.
- <i>h</i>	<i>type</i>	Same as <i>-btype</i> except for header. Default <i>type</i> for logical page header is <i>n</i> (no lines numbered).
- <i>i</i>	<i>incr</i>	<i>incr</i> is the increment value used to number logical page lines. Default <i>incr</i> is 1.
- <i>l</i>	<i>num</i>	<i>num</i> is the number of blank lines to be considered as one. For example, <i>-l2</i> results in only the second adjacent blank being numbered (if the appropriate <i>-ha</i> , <i>-ba</i> , and/or <i>-fa</i> option is set). Default <i>num</i> is 1.
- <i>n</i>	<i>format</i>	<i>format</i> is the line numbering format. Recognized values are: <i>ln</i> left justified, leading zeroes suppressed <i>rn</i> right justified, leading zeroes suppressed <i>rz</i> right justified, leading zeroes kept Default <i>format</i> is <i>rn</i> (right justified).
- <i>p</i>		Do not restart numbering at logical page delimiters.
- <i>s</i>	<i>sep</i>	<i>sep</i> is the character(s) used in separating the line number and the corresponding text line. Default <i>sep</i> is a TAB.
- <i>v</i>	<i>startnum</i>	<i>startnum</i> is the initial value used to number logical page lines. Default <i>startnum</i> is 1.
- <i>w</i>	<i>width</i>	<i>width</i> is the number of characters to be used for the line number. Default <i>width</i> is 6.

OPERANDS The following operand is supported:

file A path name of a text file to be line-numbered.

nl(1)

EXAMPLES **EXAMPLE 1** An example of the nl command

The command:

```
example% nl -v10 -i10 -d!+ filename1
```

will cause the first line of the page body to be numbered 10, the second line of the page body to be numbered 20, the third 30, and so forth. The logical page delimiters are !+.

ENVIRONMENT VARIABLES See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of nl: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred.

FILES /usr/lib/locale/locale/LC_COLLATE/CollTable
Collation table generated by localedef
/usr/lib/locale/locale/LC_COLLATE/coll.so
Shared object containing string transformation library routines

ATTRIBUTES See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/nl

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

/usr/xpg4/bin/nl

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
Interface Stability	Standard

SEE ALSO [pr\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [regex\(5\)](#), [regexp\(5\)](#), [standards\(5\)](#)

NOTES Internationalized Regular Expressions are used in the POSIX and "C" locales. In other locales, Internationalized Regular Expressions are used if the following two conditions are met:

- /usr/lib/locale/locale/LC_COLLATE/CollTable is present.
- /usr/lib/locale/locale/LC_COLLATE/coll.so is not present.

Otherwise, Simple Regular Expressions are used.

nl(1)

Internationalized Regular Expressions are explained on `regex(5)`. Simple Regular Expressions are explained on `regexp(5)`.

nm(1)

NAME	nm – print name list of an object file
SYNOPSIS	<pre>/usr/ccs/bin/nm [-ACDhlnPprRsTuVv] [-efox] [-g -u] [-t <i>format</i>] <i>file...</i> /usr/xpg4/bin/nm [-ACDhlnPprRsTuVv] [-efox] [-g -u] [-t <i>format</i>] <i>file...</i></pre>
DESCRIPTION	<p>The nm utility displays the symbol table of each ELF object file that is specified by <i>file</i>.</p> <p>If no symbolic information is available for a valid input file, the nm utility will report that fact, but not consider it an error condition.</p>
OPTIONS	<p>The output of nm may be controlled using the following options:</p> <ul style="list-style-type: none">-A Writes the full path name or library name of an object on each line.-C Demangles C++ symbol names before printing them out.-D Displays the SHT_DYNSYM symbol information. This is the symbol table used by ld.so.1 and is present even in stripped dynamic executables. By default, the SHT_SYMTAB symbol table is displayed.-e See NOTES below.-f See NOTES below.-g Writes only external (global) symbol information.-h Does not display the output heading data.-l Distinguishes between WEAK and GLOBAL symbols by appending a * to the key letter for WEAK symbols.-n Sorts external symbols by name before they are printed.-o Prints the value and size of a symbol in octal instead of decimal (equivalent to -t o).-p Produces easy to parse, terse output. Each symbol name is preceded by its value (blanks if undefined) and one of the letters:<ul style="list-style-type: none">A Absolute symbol.B bss (uninitialized data space) symbol.C COMMON symbol.D Data object symbol.F File symbol.N Symbol has no type.L Thread-Local storage symbol.S Section symbol.

T Text symbol.

U Undefined.

If the symbol's binding attribute is:

LOCAL The key letter is lower case.

WEAK The key letter is upper case. If the `-l` modifier is specified, the upper case key letter is followed by a `*`

GLOBAL The key letter is upper case.

`-P` Writes information in a portable output format, as specified in Standard Output.

`-r` Prepends the name of the object file or archive to each output line.

`-R` Prints the archive name (if present), followed by the object file and symbol name. If the `-r` option is also specified, this option is ignored.

`-s` Prints section name instead of section index.

`-t format` Writes each numeric value in the specified format. The format is dependent on the single character used as the *format* option-argument:

`d` The offset is written in decimal (default).

`o` The offset is written in octal.

`x` The offset is written in hexadecimal.

`-T` See NOTES below.

`-u` Prints undefined symbols only.

`-U` Prints long listing for each undefined symbol. See OUTPUT below.

`-v` Sorts external symbols by value before they are printed.

`-V` Prints the version of the `nm` command executing on the standard error output.

`-x` Prints the value and size of a symbol in hexadecimal instead of decimal (equivalent to `-t x`).

Options may be used in any order, either singly or in combination, and may appear anywhere in the command line. When conflicting options are specified (such as `-v` and `-n`, or `-o` and `-x`) the first is taken and the second ignored with a warning message to the user. (See `-R` for exception.)

OPERANDS

The following operand is supported:

file A path name of an object file, executable file or object-file library.

`/usr/ccs/bin/nm`
`/usr/xpg4/bin/nm`

nm(1)

OUTPUT

This section describes the nm utility's output options.

Standard Output

For each symbol, the following information will be printed:

Index	The index of the symbol. (The index appears in brackets.)	
Value	The value of the symbol is one of the following: <ul style="list-style-type: none">■ A section offset for defined symbols in a relocatable file.■ Alignment constraints for symbols whose section index is SHN_COMMON.■ A virtual address in executable and dynamic library files.	
Size	The size in bytes of the associated object.	
Type	A symbol is of one of the following types: NOTYPE No type was specified. OBJECT A data object such as an array or variable. FUNC A function or other executable code. REGI A register symbol (SPARC only). SECTION A section symbol. FILE Name of the source file. COMMON An uninitialized common block. TLS A variable associated with Thread-Local storage.	
Bind	The symbol's binding attributes. LOCAL symbols Have a scope limited to the object file containing their definition. GLOBAL symbols Are visible to all object files being combined. WEAK symbols Are essentially global symbols with a lower precedence than GLOBAL.	
Other	A field reserved for future use, currently containing 0.	
Shndx	Except for three special values, this is the section header table index in relation to which the symbol is defined. The following special values exist: ABS Indicates the symbol's value will not change through relocation. COMMON Indicates an unallocated block and the value provides alignment constraints. UNDEF Indicates an undefined symbol.	

Name The name of the symbol.

Object Name The name of the object or library if `-A` is specified.

If the `-P` option is specified, the previous information is displayed using the following portable format. The three versions differ depending on whether `-t d`, `-t o`, or `-t x` was specified, respectively:

```
"%s%s %s %d %d\n", library/object name, name, type, value, size "%s%s %s %o
%o\n", library/object name, name, type, value, size "%s%s %s %x %x\n",
library/object name, name, type, value, size
```

where *library/object name* is formatted as follows:

- If `-A` is not specified, *library/object name* is an empty string.
- If `-A` is specified and the corresponding *file* operand does not name a library:

```
"%s: ", file
```
- If `-A` is specified and the corresponding *file* operand names a library. In this case, *object file* names the object file in the library containing the symbol being described:

```
"%s[%s]: ", file, object file
```

If `-A` is not specified, then if more than one *file* operand is specified or if only one *file* operand is specified and it names a library, `nm` will write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

- If the corresponding *file* operand does not name a library:

```
"%s:\n", file
```
- If the corresponding *file* operand names a library; in this case, *object file* is the name of the file in the library containing the following symbols:

```
"%s[%s]:\n", file, object file
```

If `-P` is specified, but `-t` is not, the format is as if `-t x` had been specified.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `nm`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

```
0           Successful completion.
>0          An error occurred.
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

nm(1)

/usr/ccs/bin/nm

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

/usr/xpg4/bin/nm

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
Interface Stability	Standard

SEE ALSO [ar\(1\)](#), [as\(1\)](#), [dump\(1\)](#), [ld\(1\)](#), [ld.so.1\(1\)](#), [ar\(3HEAD\)](#), [a.out\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

NOTES The following options are obsolete because of changes to the object file format and will be deleted in a future release.

- e Prints only external and static symbols. The symbol table now contains only static and external symbols. Automatic symbols no longer appear in the symbol table. They do appear in the debugging information produced by `cc -g`, which may be examined using [dump\(1\)](#).
- f Produces full output. Redundant symbols (such as `.text`, `.data`, and so forth), which existed previously, do not exist and producing full output will be identical to the default output.
- T By default, `nm` prints the entire name of the symbols listed. Since symbol names have been moved to the last column, the problem of overflow is removed and it is no longer necessary to truncate the symbol name.

NAME	nohup – run a command immune to hangups
SYNOPSIS	<pre> /usr/bin/nohup <i>command</i> [<i>argument...</i>] /usr/bin/nohup -p [-Fa] <i>pid</i> [<i>pid...</i>] /usr/bin/nohup -g [-Fa] <i>gpid</i> [<i>gpid...</i>] /usr/xpg4/bin/nohup <i>command</i> [<i>argument...</i>] </pre>
DESCRIPTION	<p>The nohup utility invokes the named <i>command</i> with the arguments supplied. When the <i>command</i> is invoked, nohup arranges for the SIGHUP signal to be ignored by the process.</p> <p>When invoked with the <code>-p</code> or <code>-g</code> flags, nohup arranges for processes already running as identified by a list of process IDs or a list of process group IDs to become immune to hangups.</p> <p>The nohup utility can be used when it is known that <i>command</i> will take a long time to run and the user wants to log out of the terminal. When a shell exits, the system sends its children SIGHUP signals, which by default cause them to be killed. All stopped, running, and background jobs will ignore SIGHUP and continue running, if their invocation is preceded by the nohup command or if the process programmatically has chosen to ignore SIGHUP.</p> <pre> /usr/bin/nohup Processes run by /usr/bin/nohup are immune to SIGHUP (hangup) and SIGQUIT (quit) signals. </pre> <pre> /usr/bin/nohup -p [-Fa] Processes specified by ID are made immune to SIGHUP and SIGQUIT, and all output to the controlling terminal is redirected to nohup.out. If -F is specified, nohup will force control of each process. If -a is specified, nohup will change the signal disposition of SIGHUP and SIGQUIT even if the process has installed a handler for either signal. </pre> <pre> /usr/bin/nohup -g [-Fa] Every process in the same process group as the processes specified by ID are made immune to SIGHUP and SIGQUIT, and all output to the controlling terminal is redirected to nohup.out. If -F is specified, nohup will force control of each process. If -a is specified, nohup will change the signal disposition of SIGHUP and SIGQUIT even if the process has installed a handler for either signal. </pre> <pre> /usr/xpg4/bin/nohup Processes run by /usr/xpg4/bin/nohup are immune to SIGHUP. </pre> <p>The nohup utility does not arrange to make processes immune to a SIGTERM (terminate) signal, so unless they arrange to be immune to SIGTERM or the shell makes them immune to SIGTERM, they will receive it.</p>

nohup(1)

If `nohup .out` is not writable in the current directory, output is redirected to `$HOME/nohup.out`. If a file is created, the file will have read and write permission (600, see `chmod(1)`). If the standard error is a terminal, it is redirected to the standard output, otherwise it is not redirected. The priority of the process run by `nohup` is not altered.

OPTIONS The following options are supported:

- a Always changes the signal disposition of target processes. This option is valid only when specified with `-p` or `-g`.
- F Force. Grabs the target processes even if another process has control. This option is valid only when specified with `-p` or `-g`.
- g Operates on a list of process groups. This option is not valid with `-p`.
- p Operates on a list of processes. This option is not valid with `-g`.

OPERANDS The following operands are supported:

- pid* A decimal process ID to be manipulated by `nohup -p`.
- pgid* A decimal process group ID to be manipulated by `nohup -g`.
- command* The name of a command that is to be invoked. If the *command* operand names any of the special `shell_builtins(1)` utilities, the results are undefined.
- argument* Any string to be supplied as an argument when invoking the *command* operand.

EXAMPLES **EXAMPLE 1** Applying `nohup` to pipelines or command lists

It is frequently desirable to apply `nohup` to pipelines or lists of commands. This can be done only by placing pipelines and command lists in a single file, called a shell script. One can then issue:

```
example$ nohup sh file
```

and the `nohup` applies to everything in *file*. If the shell script *file* is to be executed often, then the need to type `sh` can be eliminated by giving *file* execute permission.

Add an ampersand and the contents of *file* are run in the background with interrupts also ignored (see `sh(1)`):

```
example$ nohup file &
```

EXAMPLE 2 Applying `nohup -p` to a process

```
example$ long_running_command &
example$ nohup -p `pgrep long_running_command`
```

EXAMPLE 3 Applying nohup -g to a process group

```
example$ make &
example$ ps -o sid -p $$
      SID
      81079
example$ nohup -g 'pgrep -s 81079 make'
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of nohup: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, PATH, NLSPATH, and PATH.

HOME Determine the path name of the user's home directory: if the output file `nohup.out` cannot be created in the current directory, the nohup command will use the directory named by HOME to create the file.

EXIT STATUS

The following exit values are returned:

126 *command* was found but could not be invoked.

127 An error occurred in nohup, or *command* could not be found

Otherwise, the exit values of nohup will be those of the *command* operand.

FILES

`nohup.out` The output file of the nohup execution if standard output is a terminal and if the current directory is writable.

`$HOME/nohup.out` The output file of the nohup execution if standard output is a terminal and if the current directory is not writable.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

/usr/bin/nohup

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

/usr/xpg4/bin/nohup

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	enabled
Interface Stability	Standard

SEE ALSO

`batch(1)`, `chmod(1)`, `csh(1)`, `ksh(1)`, `nice(1)`, `pgrep(1)`, `proc(1)`, `ps(1)`, `sh(1)`, `shell_builtins(1)`, `signal(3C)`, `proc(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

nohup(1)

WARNINGS If you are running the Korn shell (`ksh(1)`) as your login shell, and have `nohup`'ed jobs running when you attempt to log out, you will be warned with the message:

```
You have jobs running.
```

You will then need to log out a second time to actually log out. However, your background jobs will continue to run.

NOTES The C-shell (`csh(1)`) has a built-in command `nohup` that provides immunity from `SIGHUP`, but does not redirect output to `nohup.out`. Commands executed with `'&'` are automatically immune to `HUP` signals while in the background.

`nohup` does not recognize command sequences. In the case of the following command,

```
example$ nohup command1; command2
```

the `nohup` utility applies only to `command1`. The command,

```
example$ nohup (command1; command2)
```

is syntactically incorrect.

NAME	nroff – format documents for display or line-printer
SYNOPSIS	nroff [-ehiq] [-mname] [-nN] [-opagelist] [-raN] [-sN] [-Tname] [-uN]
DESCRIPTION	<p>The <code>nroff</code> utility formats text in the named <i>files</i> for typewriter-like devices. See also <code>troff(1)</code>.</p> <p>If no <i>file</i> argument is present, <code>nroff</code> reads the standard input. An argument consisting of a '-' is taken to be a file name corresponding to the standard input.</p>
OPTIONS	<p>The following options are supported. Options may appear in any order so long as they appear <i>before</i> the files.</p> <ul style="list-style-type: none"> -e Produces equally-spaced words in adjusted lines, using full terminal resolution. -h Uses output TAB characters during horizontal spacing to speed output and reduces output character count. TAB settings are assumed to be every 8 nominal character widths. -i Reads the standard input after the input files are exhausted. -q Does not print output that was read from an .rd request. -mname Prepends the macro file /usr/share/lib/tmac/tmac.name to the input files. -nN Numbers first generated page <i>N</i>. -opagelist Prints only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N-M</i> means pages <i>N</i> through <i>M</i>; an initial -<i>N</i> means from the beginning to page <i>N</i>; and a final <i>N-</i> means from <i>N</i> to the end. -raN Sets register <i>a</i> (one-character) to <i>N</i>. -sN Stops every <i>N</i> pages. <code>nroff</code> will halt prior to every <i>N</i> pages (default <i>N</i>=1) to allow paper loading or changing, and will resume upon receipt of a NEWLINE. -Tname Prepares output for a device of the specified <i>name</i>. Known <i>names</i> are: <ul style="list-style-type: none"> 37 Teletype Corporation Model 37 terminal — this is the default. lp tn300 GE — any line printer or terminal without half-line capability. 300 DASI-300. 300-12 DASI-300 — 12-pitch. 300S DASI-300S.

nroff(1)

300S-12	DASI-300S.
382	DASI-382 (fancy DTC 382).
450	DASI-450 (Diablo Hyterm).
450-12	DASI-450 (Diablo Hyterm) — 12-pitch.
832	AJ 832.

-uN Set the emboldening factor for the font mounted in position 3 to *N*.
If *N* is missing, then set the emboldening factor to 0.

EXAMPLES **EXAMPLE 1** Formatting with a macro package

The following command formats `users.guide` using the `-me` macro package, and stopping every 4 pages:

```
example% nroff -s4 -me users.guide
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `nroff`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

FILES

<code>/usr/tmp/trtmp*</code>	temporary file (see NOTES)
<code>/usr/share/lib/tmac/tmac.*</code>	standard macro files
<code>/usr/share/lib/nterm/*</code>	terminal driving tables for <code>nroff</code>
<code>/usr/share/lib/nterm/README</code>	index to terminal description files

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc
CSI	Enabled

SEE ALSO

`checknr(1)`, `col(1)`, `eqn(1)`, `man(1)`, `tbl(1)`, `troff(1)`, `attributes(5)`, `environ(5)`, `me(5)`, `ms(5)`, `term(5)`

NOTES

`/usr/tmp` is currently a symbolic link to `/var/tmp`.

Previous documentation incorrectly described the numeric register `yr` as being the "Last two digits of current year". `yr` is in actuality the number of years since 1900. To correctly obtain the last two digits of the current year through the year 2099, the definition given below of string register `yy` may be included in a document and subsequently used to display a two-digit year. Notice that any other available one- or two-character register name may be substituted for `yy`.

```
.\ " definition of new string register yy--last two digits of year
.\ " use yr (# of years since 1900) if it is < 100
```

```
.ie \n(yr<100 .ds yy \n(yr
.el \{          .\" else, subtract 100 from yr, store in ny
.nr ny \n(yr-100
.ie \n(ny>9 \{   .\" use ny if it is two digits
.ds yy \n(ny
.\" remove temporary number register ny
.rr ny \}
.el \{.ds yy 0
.\" if ny is one digit, append it to 0
.as yy \n(ny
.rr ny \} \}
```

od(1)

NAME	od – octal dump																		
SYNOPSIS	<pre>/usr/bin/od [-bcCDdFfOoSsvXx] [-] [file] [offset_string] /usr/bin/od [-bcCDdFfOoSsvXx] [-A address_base] [-j skip] [-N count] [-t type_string...] [-] [file...] /usr/xpg4/bin/od [-bcCDdFfOoSsvXx] [-] [file] [offset_string] /usr/xpg4/bin/od [-bcCDdFfOoSsvXx] [-A address_base] [-j skip] [-N count] [-t type_string...] [-] [file...]</pre>																		
DESCRIPTION	<p>The od command copies sequentially each input file to standard output and transforms the input data according to the output types specified by the <code>-t</code> or <code>-bcCDdFfOoSsvXx</code> options. If no output type is specified, the default output is as if <code>-t o2</code> had been specified. Multiple types can be specified by using multiple <code>-bcCDdFfOoSsvXx</code> options. Output lines are written for each type specified in the order in which the types are specified. If no <code>file</code> is specified, the standard input is used. The <code>[offset_string]</code> operand is mutually exclusive from the <code>-A</code>, <code>-j</code>, <code>-N</code>, and <code>-t</code> options. For the purposes of this description, the following terms are used:</p> <table><tr><td>word</td><td>Refers to a 16-bit unit, independent of the word size of the machine.</td></tr><tr><td>long word</td><td>Refers to a 32-bit unit.</td></tr><tr><td>double long word</td><td>Refers to a 64-bit unit.</td></tr></table>	word	Refers to a 16-bit unit, independent of the word size of the machine.	long word	Refers to a 32-bit unit.	double long word	Refers to a 64-bit unit.												
word	Refers to a 16-bit unit, independent of the word size of the machine.																		
long word	Refers to a 32-bit unit.																		
double long word	Refers to a 64-bit unit.																		
OPTIONS	<p>The following options are supported:</p> <table><tr><td><code>-A address_base</code></td><td>Specifies the input offset base. The <code>address_base</code> option-argument must be a character. The characters <code>d</code>, <code>o</code> and <code>x</code> specify that the offset base will be written in decimal, octal or hexadecimal, respectively. The character <code>n</code> specifies that the offset will not be written. Unless <code>-A n</code> is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the <code>-A address_base</code> option and the <code>[offset_string]</code> operand, the input offset base is displayed in octal.</td></tr><tr><td><code>-b</code></td><td>Interprets bytes in octal. This is equivalent to <code>-t o1</code>.</td></tr></table>	<code>-A address_base</code>	Specifies the input offset base. The <code>address_base</code> option-argument must be a character. The characters <code>d</code> , <code>o</code> and <code>x</code> specify that the offset base will be written in decimal, octal or hexadecimal, respectively. The character <code>n</code> specifies that the offset will not be written. Unless <code>-A n</code> is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the <code>-A address_base</code> option and the <code>[offset_string]</code> operand, the input offset base is displayed in octal.	<code>-b</code>	Interprets bytes in octal. This is equivalent to <code>-t o1</code> .														
<code>-A address_base</code>	Specifies the input offset base. The <code>address_base</code> option-argument must be a character. The characters <code>d</code> , <code>o</code> and <code>x</code> specify that the offset base will be written in decimal, octal or hexadecimal, respectively. The character <code>n</code> specifies that the offset will not be written. Unless <code>-A n</code> is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the <code>-A address_base</code> option and the <code>[offset_string]</code> operand, the input offset base is displayed in octal.																		
<code>-b</code>	Interprets bytes in octal. This is equivalent to <code>-t o1</code> .																		
<code>/usr/bin/od</code>	<table><tr><td><code>-c</code></td><td>Displays single-byte characters. Certain non-graphic characters appear as C-language escapes:</td></tr><tr><td></td><td><table><tr><td>null</td><td><code>\0</code></td></tr><tr><td>backspace</td><td><code>\b</code></td></tr><tr><td>form-feed</td><td><code>\f</code></td></tr><tr><td>new-line</td><td><code>\n</code></td></tr><tr><td>return</td><td><code>\r</code></td></tr><tr><td>tab</td><td><code>\t</code></td></tr></table></td></tr><tr><td></td><td>Others appear as 3-digit octal numbers. For example:</td></tr></table>	<code>-c</code>	Displays single-byte characters. Certain non-graphic characters appear as C-language escapes:		<table><tr><td>null</td><td><code>\0</code></td></tr><tr><td>backspace</td><td><code>\b</code></td></tr><tr><td>form-feed</td><td><code>\f</code></td></tr><tr><td>new-line</td><td><code>\n</code></td></tr><tr><td>return</td><td><code>\r</code></td></tr><tr><td>tab</td><td><code>\t</code></td></tr></table>	null	<code>\0</code>	backspace	<code>\b</code>	form-feed	<code>\f</code>	new-line	<code>\n</code>	return	<code>\r</code>	tab	<code>\t</code>		Others appear as 3-digit octal numbers. For example:
<code>-c</code>	Displays single-byte characters. Certain non-graphic characters appear as C-language escapes:																		
	<table><tr><td>null</td><td><code>\0</code></td></tr><tr><td>backspace</td><td><code>\b</code></td></tr><tr><td>form-feed</td><td><code>\f</code></td></tr><tr><td>new-line</td><td><code>\n</code></td></tr><tr><td>return</td><td><code>\r</code></td></tr><tr><td>tab</td><td><code>\t</code></td></tr></table>	null	<code>\0</code>	backspace	<code>\b</code>	form-feed	<code>\f</code>	new-line	<code>\n</code>	return	<code>\r</code>	tab	<code>\t</code>						
null	<code>\0</code>																		
backspace	<code>\b</code>																		
form-feed	<code>\f</code>																		
new-line	<code>\n</code>																		
return	<code>\r</code>																		
tab	<code>\t</code>																		
	Others appear as 3-digit octal numbers. For example:																		

/usr/xpg4/bin/od

- ```
echo "hello world" | od -c
0000000 h e l l o w o r l d \n
0000014
```
- c** Interprets bytes as single-byte or multibyte characters according to the current setting of the LC\_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence \*\* is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Non-graphic characters appear the same as they would using the -C option.
- C** Interprets bytes as single-byte or multibyte characters according to the current setting of the LC\_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence \*\* is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes:
- ```

null           \0
backspace     \b
form-feed     \f
new-line      \n
return        \r
tab           \t

```
- Other non-printable characters appear as one three-digit octal number for each byte in the character.
- d** Interprets words in unsigned decimal. This is equivalent to -t u2.
- D** Interprets long words in unsigned decimal. This is equivalent to -t u4.
- f** Interprets long words in floating point. This is equivalent to -t f4.
- F** Interprets double long words in extended precision. This is equivalent to -t f8.
- j skip** Jumps over *skip* bytes from the beginning of the input. The od command will read or seek past the first *skip* bytes in the concatenated input files. If the combined input is not at least *skip* bytes long, the od command will write a diagnostic message to standard error and exit with a non-zero exit status.
- By default, the *skip* option-argument is interpreted as a decimal number. With a leading 0x or 0X, the offset is interpreted as a hexadecimal number; otherwise, with a leading 0, the offset will be interpreted as an octal number. Appending the character b, k, or m to offset will cause it to be interpreted as a multiple of 512, 1024 or 1 048 576 bytes, respectively. If the *skip* number is

od(1)

	hexadecimal, any appended <code>b</code> is considered to be the final hexadecimal digit. The address is displayed starting at <code>0000000</code> , and its base is not implied by the base of the <code>skip</code> option-argument.																																																																								
<code>-N count</code>	Formats no more than <code>count</code> bytes of input. By default, <code>count</code> is interpreted as a decimal number. With a leading <code>0x</code> or <code>0X</code> , <code>count</code> is interpreted as a hexadecimal number; otherwise, with a leading <code>0</code> , it is interpreted as an octal number. If <code>count</code> bytes of input (after successfully skipping, if <code>-jskip</code> is specified) are not available, it will not be considered an error. The <code>od</code> command will format the input that is available. The base of the address displayed is not implied by the base of the <code>count</code> option-argument.																																																																								
<code>-o</code>	Interprets words in octal. This is equivalent to <code>-t o2</code> .																																																																								
<code>-O</code>	Interprets long words in unsigned octal. This is equivalent to <code>-t o4</code> .																																																																								
<code>-s</code>	Interprets words in signed decimal. This is equivalent to <code>-t d2</code> .																																																																								
<code>-S</code>	Interprets long words in signed decimal. This is equivalent to <code>-t d4</code> .																																																																								
<code>-t type_string</code>	Specifies one or more output types. The <code>type_string</code> option-argument must be a string specifying the types to be used when writing the input data. The string must consist of the type specification characters: <ul style="list-style-type: none"> a <i>Named character</i>. Interprets bytes as named characters. Only the least significant seven bits of each byte will be used for this type specification. Bytes with the values listed in the following table will be written using the corresponding names for those characters. <p style="text-align: center;">Named Characters in od</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Value</th> <th>Name</th> <th>Value</th> <th>Name</th> <th>Value</th> <th>Name</th> </tr> </thead> <tbody> <tr> <td>\000</td> <td>nul</td> <td>\001</td> <td>soh</td> <td>\002</td> <td>stx</td> <td>\003</td> <td>etx</td> </tr> <tr> <td>\004</td> <td>eot</td> <td>\005</td> <td>enq</td> <td>\006</td> <td>ack</td> <td>\007</td> <td>bel</td> </tr> <tr> <td>\010</td> <td>bs</td> <td>\011</td> <td>ht</td> <td>\012</td> <td>lf</td> <td>\013</td> <td>vt</td> </tr> <tr> <td>\014</td> <td>ff</td> <td>\015</td> <td>cr</td> <td>\016</td> <td>so</td> <td>\017</td> <td>si</td> </tr> <tr> <td>\020</td> <td>dle</td> <td>\021</td> <td>dc1</td> <td>\022</td> <td>dc2</td> <td>\023</td> <td>dc3</td> </tr> <tr> <td>\024</td> <td>dc4</td> <td>\025</td> <td>nak</td> <td>\026</td> <td>syn</td> <td>\027</td> <td>etb</td> </tr> <tr> <td>\030</td> <td>can</td> <td>\031</td> <td>em</td> <td>\032</td> <td>sub</td> <td>\033</td> <td>esc</td> </tr> <tr> <td>\034</td> <td>fs</td> <td>\035</td> <td>gs</td> <td>\036</td> <td>rs</td> <td>\037</td> <td>us</td> </tr> </tbody> </table>	Value	Name	Value	Name	Value	Name	Value	Name	\000	nul	\001	soh	\002	stx	\003	etx	\004	eot	\005	enq	\006	ack	\007	bel	\010	bs	\011	ht	\012	lf	\013	vt	\014	ff	\015	cr	\016	so	\017	si	\020	dle	\021	dc1	\022	dc2	\023	dc3	\024	dc4	\025	nak	\026	syn	\027	etb	\030	can	\031	em	\032	sub	\033	esc	\034	fs	\035	gs	\036	rs	\037	us

- c** *Character*. Interprets bytes as single-byte or multibyte characters specified by the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes: \0, \a, \b, \f, \n, \r, \t, \v. Other non-printable characters appear as one three-digit octal number for each byte in the character.

The type specification characters *d*, *f*, *o*, *u*, and *x* can be followed by an optional unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type.

- f** *Floating point*. Can be followed by an optional *F*, *D*, or *L* indicating that the conversion should be applied to an item of type *float*, *double*, or *long double*, respectively.
- d, o, u, and x** *Signed decimal, octal, unsigned decimal, and hexadecimal*, respectively. Can be followed by an optional *C*, *S*, *I*, or *L* indicating that the conversion should be applied to an item of type *char*, *short*, *int*, or *long*, respectively.

Multiple types can be concatenated within the same *type_string* and multiple *-t* options can be specified. Output lines are written for each type specified in the order in which the type specification characters are specified.

- v** Shows all input data (verbose). Without the *-v* option, all groups of output lines that would be identical to the immediately preceding output line (except for byte offsets), will be replaced with a line containing only an asterisk (*).
- x** Interprets words in hex. This is equivalent to *-t x2*.
- X** Interprets long words in hex. This is equivalent to *-t x4*.

OPERANDS The following operands are supported for both */usr/bin/od* and */usr/xpg4/bin/od*:

- Uses the standard input in addition to any files specified. When this operand is not given, the standard input is used only if no *file*

od(1)

operands are specified.

/usr/bin/od

The following operands are supported for `/usr/bin/od` only:

file

A path name of a file to be read. If no *file* operands are specified, the standard input will be used. If there are no more than two operands, none of the `-A`, `-j`, `-N`, or `-t` options is specified, and *any* of the following are true:

1. the first character of the last operand is a plus sign (+)
2. the first character of the second operand is numeric
3. the first character of the second operand is `x` and the second character of the second operand is a lower-case hexadecimal character or digit
4. the second operand is named "`x`"
5. the second operand is named "."

then the corresponding operand is assumed to be an offset operand rather than a file operand.

Without the `-N` count option, the display continues until an end-of-file is reached.

[+] [0] *offset* [.] [b|B]

[+] [0] [*offset*] [.]

[+] [0x|x] [*offset*]

[+] [0x|x] *offset* [B]

The *offset_string* operand specifies the byte offset in the file where dumping is to commence. The offset is interpreted in octal bytes by default. If *offset* begins with "0", it is interpreted in octal. If *offset* begins with "x" or "0x", it is interpreted in hexadecimal and any appended "b" is considered to be the final hexadecimal digit. If "." is appended, the offset is interpreted in decimal. If "b" or "B" is appended, the offset is interpreted in units of 512 bytes. If the *file* argument is omitted, the *offset* argument must be preceded by a plus sign (+). The address is displayed starting at the given offset. The radix of the address will be the same as the radix of the offset, if specified, otherwise it will be octal. Decimal overrides octal, and it is an error to specify both hexadecimal and decimal conversions in the same offset operand.

/usr/xpg4/bin/od

The following operands are supported for `/usr/xpg4/bin/od` only:

file

Same as `/usr/bin/od`, except only one of the first two conditions must be true.

```
[+] [0] offset [.] [b|B]
+ [offset] [.]
[+] [0x] [offset]
[+] [0x] offset [B]
+x [offset]
+xoffset [B]
```

Description of *offset_string* is the same as for
/usr/bin/od.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `od`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

```
0          Successful completion.
>0        An error occurred.
```

on(1)

NAME	on – execute a command on a remote system, but with the local environment										
SYNOPSIS	on [-i] [-d] [-n] <i>host command [argument] ...</i>										
DESCRIPTION	<p>The on program is used to execute commands on another system, in an environment similar to that invoking the program. All environment variables are passed, and the current working directory is preserved. To preserve the working directory, the working file system must be either already mounted on the host or be exported to it. Relative path names will only work if they are within the current file system; absolute path names may cause problems.</p> <p>The standard input is connected to the standard input of the remote command, and the standard output and the standard error from the remote command are sent to the corresponding files for the on command.</p>										
OPTIONS	<p>-i Interactive mode. Use remote echoing and special character processing. This option is needed for programs that expect to be talking to a terminal. All terminal modes and window size changes are propagated.</p> <p>-d Debug mode. Print out some messages as work is being done.</p> <p>-n No Input. This option causes the remote program to get EOF when it reads from the standard input, instead of passing the standard input from the standard input of the on program. For example, -n is necessary when running commands in the background with job control.</p>

<code>unknown host</code>	Host name not found.										
<code>cannot connect to server</code>	Host down or not running the server.										
<code>can't find</code>	Problem finding the working directory.										
<code>can't locate mount point</code>	Problem finding current file system.										
<code>RPC: Authentication error</code>	The server requires DES authentication and you do not have a secret key registered with <code>keyserv</code> . Perhaps you logged in without a password. Try to <code>keylogin</code> . If that fails try to set your <code>publickey</code> with <code>chkey</code> .										

BUGS When the working directory is remote mounted over NFS, a CTRL-Z hangs the window.

Root cannot use on.

optisa(1)

NAME optisa – determine which variant instruction set is optimal to use

SYNOPSIS **optisa** *instruction_set...*

DESCRIPTION optisa prints which *instruction_set* out of the ones specified in the command will perform best on this machine. In this case, “best” is defined by the order in which instruction set names are returned by *isalist(1)*. Possible values for *instruction_set* are given in *isalist(5)*.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

EXIT STATUS The following exit values are returned:

0 One of the *instruction_set* values you specified is printed by this command.

1 There is no output; that is, this machine cannot use any *instruction_set* that you specified with the *optisa* command.

SEE ALSO *isalist(1)*, *uname(1)*, *attributes(5)*, *isalist(5)*

NOTES *optisa* is preferable to *uname -p* or *uname -m* (see *uname(1)*) in determining which of several binary versions of a given program should be used on the given machine.

NAME	pack, pcat, unpack – compress and expand files
SYNOPSIS	<p>pack [-f] [-] <i>file...</i></p> <p>pcat <i>file...</i></p> <p>unpack <i>file...</i></p>
pack	<p>The pack command attempts to store the specified files in a compressed form. Wherever possible (and useful), each input file <i>file</i> is replaced by a packed file <i>file.z</i> with the same access modes, access and modified dates, and owner as those of <i>file</i>. If pack is successful, <i>file</i> will be removed.</p> <p>The amount of compression obtained depends on the size of the input file and the character frequency distribution. Because a decoding tree forms the first part of each <i>.z</i> file, it is usually not worthwhile to pack files smaller than three blocks, unless the character frequency distribution is very skewed, which may occur with printer plots or pictures.</p> <p>Typically, text files are reduced to 60-75% of their original size. Load modules, which use a larger character set and have a more uniform distribution of characters, show little compression, the packed versions being about 90% of the original size.</p> <p>pack returns a value that is the number of files that it failed to compress.</p> <p>No packing will occur if:</p> <ul style="list-style-type: none"> ■ the file appears to be already packed ■ the file name has more than 14 – 2 bytes ■ the file has links ■ the file is a directory ■ the file cannot be opened ■ the file is empty ■ no disk storage blocks will be saved by packing ■ a file called <i>file.z</i> already exists ■ the <i>.z</i> file cannot be created ■ an I/O error occurred during processing. <p>The last segment of the file name must contain no more than 14 – 2 bytes to allow space for the appended <i>.z</i> extension. Directories cannot be compressed.</p>
pcat	<p>The pcat command does for packed files what cat(1) does for ordinary files, except that pcat cannot be used as a filter. The specified files are unpacked and written to the standard output.</p> <p>pcat returns the number of files it was unable to unpack. Failure may occur if:</p> <ul style="list-style-type: none"> ■ the file cannot be opened; ■ the file does not appear to be the output of pack.

pack(1)

unpack	<p>The <code>unpack</code> command expands files created by <code>pack</code>. For each <code>file</code> specified in the command, a search is made for a file called <code>file.z</code> (or just <code>file</code>, if <code>file</code> ends in <code>.z</code>). If this file appears to be a packed file, it is replaced by its expanded version. The new file has the <code>.z</code> suffix stripped from its name, and has the same access modes, access and modification dates, and owner as those of the packed file.</p> <p><code>unpack</code> returns a value that is the number of files it was unable to unpack. Failure may occur for the same reasons that it may in <code>pcat</code>, as well as for the following:</p> <ul style="list-style-type: none">■ a file with the “unpacked” name already exists;■ the unpacked file cannot be created.■ the filename (excluding the <code>.z</code> extension) has more than 14 bytes.
OPTIONS	<p>The following options are supported by <code>pack</code>:</p> <p><code>-f</code> Forces packing of <code>file</code>. This is useful for causing an entire directory to be packed even if some of the files will not benefit. Packed files can be restored to their original form using <code>unpack</code> or <code>pcat</code>.</p>
OPERANDS	<p>The following operands are supported:</p> <p><code>file</code> A path name of a file to be packed, unpacked, or <code>pcat</code>ed; <code>file</code> can include or omit the <code>.z</code> suffix.</p> <p><code>-</code> <code>pack</code> uses Huffman (minimum redundancy) codes on a byte-by-byte basis. If the <code>-</code> argument is used, an internal flag is set that causes the number of times each byte is used, its relative frequency, and the code for the byte to be printed on the standard output. Additional occurrences of <code>-</code> in place of <code>file</code> will cause the internal flag to be set and reset.</p>
USAGE	<p>See <code>largefile(5)</code> for the description of the behavior of <code>pack</code>, <code>pcat</code>, and <code>unpack</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).</p>
EXAMPLES	<p>EXAMPLE 1 Viewing a Packed File</p> <p>To view a packed file named <code>file.z</code> use:</p> <pre>example% pcat file.z</pre> <p>or just:</p> <pre>example% pcat file</pre> <p>EXAMPLE 2 Making and Unpacked Copy:</p> <p>To make an unpacked copy, say <code>nnn</code>, of a packed file named <code>file.z</code> (without destroying <code>file.z</code>) use the command:</p> <pre>example% pcat file >nnn</pre>

pack(1)

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `pack`, `pcat`, and `unpack`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred. The number of files the command failed to pack/unpack is returned.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO | `getpagesize(3C)`, `getpagesizes(3C)`, `attributes(5)`

NAME	pargs – print process arguments, environment variables, or auxiliary vector
SYNOPSIS	pargs [-aceFx] [<i>pid</i> <i>core</i> ...]
DESCRIPTION	<p>The pargs utility examines a target process or process core file and prints arguments, environment variables and values, or the process auxiliary vector.</p> <p>pargs outputs unprintable characters as escaped octal in the format <code>\xxx</code>, unless the character is one of the characters specified in the "Escape Sequences" section of <code>formats(5)</code>, in which case the character is printed as specified in that section.</p> <p>pargs attempts to be sensitive to the locale of the target process. If the target process and the pargs process do not share a common character encoding, pargs attempts to employ the <code>iconv(3C)</code> facility to generate a printable version of the extracted strings. In the event that such a conversion is impossible, strings are displayed as 7-bit ASCII.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Prints process arguments as contained in <code>argv []</code> (default). -c Treats strings in the target process as though they were encoded in 7-bit ASCII, regardless of the locale of the target. The use of <code>iconv(3C)</code> is suppressed. -e Prints process environment variables and values as pointed at by the <code>_environ</code> symbol or by <code>pr_envp</code> in <code>/proc/pid/psinfo</code>. -F Force. Grabs the target process even if another process has control. -x Prints process auxiliary vector.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"> <i>pid</i> Process ID list. <i>core</i> Process core file.
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 Successful operation. non-zero An error has occurred (such as no such process, permission denied, or invalid option).
FILES	<code>/proc/pid/*</code> Process information and control files.

NAME	passwd – change login password and password attributes
SYNOPSIS	<pre> passwd [-r files -r ldap -r nis -r nisplus] [name] passwd [-r files] [-egh] [name] passwd [-r files] -s [-a] passwd [-r files] -s [name] passwd [-r files] [-d -l] [-f] [-n min] [-w warn] [-x max] name passwd -r ldap [-egh] [name] passwd -r nis [-egh] [name] passwd -r nisplus [-egh] [-D domainname] [name] passwd -r nisplus -s [-a] passwd -r nisplus [-D domainname] -s [name] passwd -r nisplus [-l] [-f] [-n min] [-w warn] [-x max] [-D domainname] name </pre>
DESCRIPTION	<p>The <code>passwd</code> command changes the password or lists password attributes associated with the user's login <i>name</i>. Additionally, privileged users may use <code>passwd</code> to install or change passwords and attributes associated with any login <i>name</i>.</p> <p>When used to change a password, <code>passwd</code> prompts everyone for their old password, if any. It then prompts for the new password twice. When the old password is entered, <code>passwd</code> checks to see if it has "aged" sufficiently. If "aging" is insufficient, <code>passwd</code> terminates; see <code>pwconv(1M)</code>, <code>nistbladm(1)</code>, and <code>shadow(4)</code> for additional information.</p> <p>When LDAP, NIS, or NIS+ is in effect on a system, <code>passwd</code> changes the NIS or NIS+ database. The NIS or NIS+ password may be different from the password on the local machine. If NIS or NIS+ is running, use <code>passwd -r</code> to change password information on the local machine.</p> <p>The <code>pwconv</code> command creates and updates <code>/etc/shadow</code> with information from <code>/etc/passwd</code>. <code>pwconv</code> relies on a special value of 'x' in the password field of <code>/etc/passwd</code>. This value of 'x' indicates that the password for the user is already in <code>/etc/shadow</code> and should not be modified.</p> <p>If aging is sufficient, a check is made to ensure that the new password meets construction requirements. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated for, at most, two more times.</p> <p>Passwords must be constructed to meet the following requirements:</p> <ul style="list-style-type: none"> ■ Each password must have <code>PASSLENGTH</code> characters, where <code>PASSLENGTH</code> is defined in <code>/etc/default/passwd</code> and is set to 6. Only the first eight characters are significant.

passwd(1)

- Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, "alphabetic" refers to all upper or lower case letters.
- Each password must differ from the user's login *name* and any reverse or circular shift of that login *name*. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.
- New passwords must differ from the old by at least three characters. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

If all requirements are met, by default, the `passwd` command will consult `/etc/nsswitch.conf` to determine in which repositories to perform password update. It searches the `passwd` and `passwd_compat` entries. The sources (repositories) associated with these entries will be updated. However, the password update configurations supported are limited to the following cases. Failure to comply with the configurations will prevent users from logging onto the system. The password update configurations are:

- `passwd: files`
- `passwd: files ldap`
- `passwd: files nis`
- `passwd: files nisplus`
- `passwd: compat (==> files nis)`
- `passwd: compat (==> files ldap)`
`passwd_compat: ldap`
- `passwd: compat (==> files nisplus)`
`passwd_compat: nisplus`

Network administrators, who own the NIS+ password table, may change any password attributes.

In the `files` case, super-users (for instance, real and effective uid equal to 0, see `id(1M)` and `su(1M)`) may change any password. Hence, `passwd` does not prompt privileged users for the old password. Privileged users are not forced to comply with password aging and password construction requirements. A privileged user can create a null password by entering a carriage return in response to the prompt for a new password. (This differs from `passwd -d` because the "password" prompt will still be displayed.) If NIS is in effect, superuser on the root master can change any password without being prompted for the old NIS `passwd`, and is not forced to comply with password construction requirements.

Normally, `passwd` entered with no arguments will change the password of the current user. When a user logs in and then invokes `su(1M)` to become super-user or another user, `passwd` will change the original user's password, not the password of the super-user or the new user.

Any user may use the `-s` option to show password attributes for his or her own login *name*, provided they are using the `-r nisplus` argument. Otherwise, the `-s` argument is restricted to the superuser.

The format of the display will be:

```
name status mm/dd/yy min max warn
```

or, if password aging information is not present,

```
name status
```

where

<i>name</i>	The login ID of the user.
<i>status</i>	The password status of <i>name</i> : PS stands for passworded or locked, LK stands for locked, and NP stands for no password.
<i>mm/dd/yy</i>	The date password was last changed for <i>name</i> . Notice that all password aging dates are determined using Greenwich Mean Time (Universal Time) and therefore may differ by as much as a day in other time zones.
<i>min</i>	The minimum number of days required between password changes for <i>name</i> . MINWEEKS is found in <code>/etc/default/passwd</code> and is set to NULL.
<i>max</i>	The maximum number of days the password is valid for <i>name</i> . MAXWEEKS is found in <code>/etc/default/passwd</code> and is set to NULL.
<i>warn</i>	The number of days relative to <i>max</i> before the password expires and the <i>name</i> will be warned.

Security passwd uses pam(3PAM) for password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the password modules to be used for passwd. Here is a partial `pam.conf` file with entries for the passwd command using the `passwd-auth` module:

```
passwd  auth  required  pam_passwd_auth.so.1
```

If there are no entries for the `passwd` service, then the entries for the "other" service will be used. If multiple password modules are listed, then the user may be prompted for multiple passwords.

OPTIONS The following options are supported:

<code>-a</code>	Shows password attributes for all entries. Use only with the <code>-s</code> option. <i>name</i> must not be provided. For the <code>nisplus</code> repository, this will show only the entries in the NIS+ password table in the local domain that the invoker is authorized to "read". For the <code>files</code> repository, this is restricted to the superuser.
-----------------	--

passwd(1)

- D *domainname* Consults the `passwd.org_dir` table in *domainname*. If this option is not specified, the default *domainname* returned by `nis_local_directory(3NSL)` will be used. This domain name is the same as that returned by `domainname(1M)`.
- e Changes the login shell. For the `files` repository, this only works for the super-user. Normal users may change the `ldap`, `nis`, or `nisplus` repositories. The choice of shell is limited by the requirements of `getusershell(3C)`. If the user currently has a shell that is not allowed by `getusershell`, only root may change it.
- g Changes the `gecos` (finger) information. For the `files` repository, this only works for the superuser. Normal users may change the `ldap`, `nis`, or `nisplus` repositories.
- h Changes the home directory.
- r Specifies the repository to which an operation is applied. The supported repositories are `files`, `ldap`, `nis`, or `nisplus`.
- s *name* Shows password attributes for the login *name*. For the `nisplus` repository, this works for everyone. However for the `files` repository, this only works for the superuser. It does not work at all for the `nis` repository which does not support password aging.

Privileged User Options

Only a privileged user can use the following options:

- d Deletes password for *name* and unlocks the account. The login *name* will not be prompted for password. It is only applicable to the `files` repository.
- f Forces the user to change password at the next login by expiring the password for *name*.
- l Locks password entry for *name*. See the `-d` option for unlocking the account.
- n *min* Sets minimum field for *name*. The *min* field contains the minimum number of days between password changes for *name*. If *min* is greater than *max*, the user may not change the password. Always use this option with the `-x` option, unless *max* is set to `-1` (aging turned off). In that case, *min* need not be set.
- w *warn* Sets `warn` field for *name*. The *warn* field contains the number of days before the password expires and the user is warned. This option is not valid if password aging is disabled.
- x *max* Sets maximum field for *name*. The *max* field contains the number of days that the password is valid for *name*. The aging for *name* will be turned off immediately if *max* is set to `-1`. If it is set to `0`, then the user is forced to change the password at the next login session.

and aging is turned off.

OPERANDS	The following operand is supported:
	<i>name</i> User login name.
ENVIRONMENT VARIABLES	<p>If any of the LC_* variables, that is, LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY (see <code>environ(5)</code>), are not set in the environment, the operational behavior of <code>passwd</code> for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how <code>passwd</code> behaves.</p> <p>LC_CTYPE Determines how <code>passwd</code> handles characters. When LC_CTYPE is set to a valid value, <code>passwd</code> can display and handle text and filenames containing valid characters for that locale. <code>passwd</code> can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. <code>passwd</code> can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.</p> <p>LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).</p>
EXIT STATUS	<p>The <code>passwd</code> command exits with one of the following values:</p> <p>0 Success.</p> <p>1 Permission denied.</p> <p>2 Invalid combination of options.</p> <p>3 Unexpected failure. Password file unchanged.</p> <p>4 Unexpected failure. Password file(s) missing.</p> <p>5 Password file(s) busy. Try again later.</p> <p>6 Invalid argument to option.</p> <p>7 Aging option is disabled.</p> <p>8 No memory.</p> <p>9 System error.</p> <p>10 Account expired.</p>

passwd(1)

FILES	/etc/oshadow	
	/etc/shells	
	/etc/passwd	Password file.
	/etc/shadow	Shadow password file.
	/etc/default/passwd	Default values can be set for the following flags in /etc/default/passwd. For example: MAXWEEKS=26
	MAXWEEKS	Maximum time period that password is valid.
	MINWEEKS	Minimum time period before the password can be changed.
	PASSLENGTH	Minimum length of password, in characters.
	WARNWEEKS	Time period until warning of date of password's ensuing expiration.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

CSI	Enabled

SEE ALSO finger(1), login(1), nistbladm(1), domainname(1M), eeprom(1M), id(1M), passmgmt(1M), pwconv(1M), su(1M), useradd(1M), userdel(1M), usermod(1M), crypt(3C), getpwnam(3C), getspnam(3C), getusershell(3C), nis_local_directory(3NSL), pam(3PAM), loginlog(4), nsswitch.conf(4), pam.conf(4), passwd(4), shadow(4), attributes(5), environ(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_ldap(5), pam_unix(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5)

NOTES The pam_unix(5) module might not be supported in a future release. Similar functionality is provided by pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), and pam_passwd_auth(5).

The nispasswd and ypasswd commands are wrappers around passwd. Use of nispasswd and ypasswd is discouraged. Use passwd -r *repository_name* instead.

passwd(1)

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

paste(1)

NAME	paste – merge corresponding or subsequent lines of files								
SYNOPSIS	paste [-s] [-d <i>list</i>] <i>file...</i>								
DESCRIPTION	<p>The <code>paste</code> utility will concatenate the corresponding lines of the given input files, and write the resulting lines to standard output.</p> <p>The default operation of <code>paste</code> will concatenate the corresponding lines of the input files. The <code>NEWLINE</code> character of every line except the line from the last input file will be replaced with a <code>TAB</code> character.</p> <p>If an EOF (end-of-file) condition is detected on one or more input files, but not all input files, <code>paste</code> will behave as though empty lines were read from the files on which EOF was detected, unless the <code>-s</code> option is specified.</p>								
OPTIONS	<p>The following options are supported:</p> <p><code>-d list</code> Unless a backslash character (\) appears in <i>list</i>, each character in <i>list</i> is an element specifying a delimiter character. If a backslash character appears in <i>list</i>, the backslash character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default <code>TAB</code> character, to replace the <code>NEWLINE</code> character of the input lines. The elements in <i>list</i> are used circularly. That is, when the list is exhausted, the first element from the list is reused.</p> <p>When the <code>-s</code> option is specified:</p> <ul style="list-style-type: none">■ The last newline character in a file will not be modified.■ The delimiter will be reset to the first element of <i>list</i> after each <i>file</i> operand is processed. <p>When the option is not specified:</p> <ul style="list-style-type: none">■ The <code>NEWLINE</code> characters in the file specified by the last <i>file</i> will not be modified.■ The delimiter will be reset to the first element of <i>list</i> each time a line is processed from each file. <p>If a backslash character appears in <i>list</i>, it and the character following it will be used to represent the following delimiter characters:</p> <table><tr><td> \n</td><td>Newline character.</td></tr><tr><td> \t</td><td>Tab character.</td></tr><tr><td> \\</td><td>Backslash character.</td></tr><tr><td> \0</td><td>Empty string (not a null character). If \0 is immediately followed by the character <i>x</i>, the character <i>X</i>, or any character defined by the <code>LC_CTYPE</code> <code>digit</code> keyword, the results are unspecified.</td></tr></table>	\n	Newline character.	\t	Tab character.	\\	Backslash character.	\0	Empty string (not a null character). If \0 is immediately followed by the character <i>x</i> , the character <i>X</i> , or any character defined by the <code>LC_CTYPE</code> <code>digit</code> keyword, the results are unspecified.
\n	Newline character.								
\t	Tab character.								
\\	Backslash character.								
\0	Empty string (not a null character). If \0 is immediately followed by the character <i>x</i> , the character <i>X</i> , or any character defined by the <code>LC_CTYPE</code> <code>digit</code> keyword, the results are unspecified.								

If any other characters follow the backslash, the results are unspecified.

-s Concatenate all of the lines of each separate input file in command line order. The `NEWLINE` character of every line except the last line in each input file will be replaced with the `TAB` character, unless otherwise specified by the `-d` option.

OPERANDS The following operand is supported:

file A path name of an input file. If `-` is specified for one or more of the *files*, the standard input will be used. The standard input will be read one line at a time, circularly, for each instance of `-`. Implementations support pasting of at least 12 *file* operands.

USAGE See `largefile(5)` for the description of the behavior of `paste` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Listing a directory in one column

```
example% ls | paste -d" " -
```

EXAMPLE 2 Listing a directory in four columns

```
example% ls | paste - - - -
```

EXAMPLE 3 Combining pairs of lines from a file into single lines

```
example% paste -s -d"\ t\ n" file
```

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `paste`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled
Interface Stability	Standard

SEE ALSO `cut(1)`, `grep(1)`, `pr(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

paste(1)

DIAGNOSTICS

"line too long"

Output lines are restricted to 511 characters.

"too many files"

Except for -s option, no more than 12 input files may be specified.

"no delimiters"

The -d option was specified with an empty list.

"cannot open file"

The specified file cannot be opened.

NAME	patch – apply changes to files
SYNOPSIS	patch [-b1NR] [-c -e -n -u] [-d <i>dir</i>] [-D <i>define</i>] [-i <i>patchfile</i>] [-o <i>outfile</i>] [-p <i>num</i>] [-r <i>rejectfile</i>] [<i>file</i>]
DESCRIPTION	<p>The <code>patch</code> command reads a source (patch) file containing any of the three forms of difference (diff) listings produced by the <code>diff(1)</code> command (normal, context or in the style of <code>ed(1)</code>) and apply those differences to a file. By default, <code>patch</code> reads from the standard input.</p> <p><code>patch</code> attempts to determine the type of the <code>diff</code> listing, unless overruled by a <code>-c</code>, <code>-e</code>, or <code>-n</code> option.</p> <p>If the patch file contains more than one patch, <code>patch</code> will attempt to apply each of them as if they came from separate patch files. (In this case the name of the patch file must be determinable for each <code>diff</code> listing.)</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -b Saves a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix <code>.orig</code> appended to it. If the file already exists, it will be overwritten. If multiple patches are applied to the same file, the <code>.orig</code> file will be written only for the first patch. When the <code>-o outfile</code> option is also specified, <code>file.orig</code> will not be created but, if <code>outfile</code> already exists, <code>outfile.orig</code> will be created. -c Interprets the patch file as a context difference (the output of the command <code>diff</code> when the <code>-c</code> or <code>-C</code> options are specified). -d <i>dir</i> Changes the current directory to <i>dir</i> before processing as described in EXTENDED DESCRIPTION. -D <i>define</i> Marks changes with the C preprocessor construct: <pre style="margin-left: 2em;">#ifdef <i>define</i> . . . #endif</pre> <p>The option-argument <i>define</i> will be used as the differentiating symbol.</p> -e Interprets the patch file as an <code>ed</code> script, rather than a <code>diff</code> script. -i <i>patchfile</i> Reads the patch information from the file named by the path name <i>patchfile</i>, rather than the standard input. -l (The letter ell.) Causes any sequence of blank characters in the difference script to match any sequence of blank characters in the input file. Other characters will be matched exactly. -n Interprets the script as a normal difference. -N Ignores patches where the differences have already been applied to the file; by default, already-applied patches are rejected.

patch(1)

<code>-o outfile</code>	Instead of modifying the files (specified by the <i>file</i> operand or the difference listings) directly, writes a copy of the file referenced by each patch, with the appropriate differences applied, to <i>outfile</i> . Multiple patches for a single file will be applied to the intermediate versions of the file created by any previous patches, and will result in multiple, concatenated versions of the file being written to <i>outfile</i> .
<code>-p num</code>	For all path names in the patch file that indicate the names of files to be patched, deletes <i>num</i> path name components from the beginning of each path name. If the path name in the patch file is absolute, any leading slashes are considered the first component (that is, <code>-p 1</code> removes the leading slashes). Specifying <code>-p 0</code> causes the full path name to be used. If <code>-p</code> is not specified, only the basename (the final path name component) is used.
<code>-R</code>	Reverses the sense of the patch script. That is, assumes that the difference script was created from the new version to the old version. The <code>-R</code> option cannot be used with <code>ed</code> scripts. <code>patch</code> attempts to reverse each portion of the script before applying it. Rejected differences will be saved in swapped format. If this option is not specified, and until a portion of the patch file is successfully applied, <code>patch</code> attempts to apply each portion in its reversed sense as well as in its normal sense. If the attempt is successful, the user will be prompted to determine if the <code>-R</code> option should be set.
<code>-r rejectfile</code>	Overrides the default reject file name. In the default case, the reject file will have the same name as the output file, with the suffix <code>.rej</code> appended to it. See Patch Application.
<code>-u</code>	Interprets the patch file as a unified context difference, that is, the output of the command <code>diff</code> when the <code>-u</code> or <code>-U</code> options are specified.

OPERANDS The following operand is supported:

file A path name of a file to patch.

USAGE The `-R` option will not work with `ed` scripts because there is too little information to reconstruct the reverse operation.

The `-p` option makes it possible to customize a patch file to local user directory structures without manually editing the patch file. For example, if the file name in the patch file was `/curds/whey/src/blurfl/blurfl.c`:

- Setting `-p 0` gives the entire path name unmodified.
- Setting `-p 1` gives:

```
curds/whey/src/blurfl/blurfl.c
```

	<ul style="list-style-type: none"> ■ Without the leading slash, <code>-p 4</code> gives: <pre>blurfl/blurfl.c</pre> ■ Not specifying <code>-p</code> at all gives: <pre>blurfl.c</pre> <p>When using <code>-b</code> in some file system implementations, the saving of a <code>.orig</code> file may produce unwanted results. In the case of 12-, 13-, or 14-character file names, on file systems supporting 14-character maximum file names, the <code>.orig</code> file will overwrite the new file.</p>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>patch</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , <code>LC_TIME</code> , and <code>NLSPATH</code> .
OUTPUT FILES	The output of <code>patch</code> the save files (<code>.orig</code> suffixes) and the reject files (<code>.rej</code> suffixes) will be text files.
EXTENDED DESCRIPTION	<p>A patch file may contain patching instructions for more than one file. File names are determined as specified in <code>Patch Determination</code>. When the <code>-b</code> option is specified, for each patched file, the original will be saved in a file of the same name with the suffix <code>.orig</code> appended to it.</p> <p>For each patched file, a reject file may also be created as noted in <code>Patch Application</code>. In the absence of an <code>-r</code> option, the name of this file will be formed by appending the suffix <code>.rej</code> to the original file name.</p>
Patch File Format	<p>The patch file must contain zero or more lines of header information followed by one or more patches. Each patch must contain zero or more lines of file name identification in the format produced by <code>diff -c</code>, and one or more sets of <code>diff</code> output, which are customarily called hunks.</p> <p><code>patch</code> recognizes the following expression in the header information:</p> <pre>Index: <i>pathname</i> The file to be patched is named <i>pathname</i>.</pre> <p>If all lines (including headers) within a patch begin with the same leading sequence of blank characters, <code>patch</code> will remove this sequence before proceeding. Within each patch, if the type of difference is context, <code>patch</code> recognizes the following expressions:</p> <pre>* * * <i>filename timestamp</i> The patches arose from <i>filename</i>.</pre> <pre>- - - <i>filename timestamp</i> The patches should be applied to <i>filename</i>.</pre> <p>Each hunk within a patch must be the <code>diff</code> output to change a line range within the original file. The line numbers for successive hunks within a patch must occur in ascending order.</p>

patch(1)

File Name Determination

If no *file* operand is specified, `patch` performs the following steps to obtain a path name:

1. If the patch contains the strings `***` and `--`, `patch` strips components from the beginning of each path name (depending on the presence or value of the `-p` option), then tests for the existence of both files in the current directory (or directory specified with the `-d` option).
2. If both files exist, `patch` assumes that no path name can be obtained from this step. If the header information contains a line with the string `Index:`, `patch` strips components from the beginning of the path name (depending on `-p`), then tests for the existence of this file in the current directory (or directory specified with the `-d` option).
3. If an SCCS directory exists in the current directory, `patch` will attempt to perform a `get -e SCCS/s.filename` command to retrieve an editable version of the file.
4. If no path name can be obtained by applying the previous steps, or if the path names obtained do not exist, `patch` will write a prompt to standard output and request a file name interactively from standard input.

Patch Application

If the `-c`, `-e`, `-n`, or `-u` option is present, `patch` will interpret information within each hunk as a context difference, an `ed` difference, a normal difference, or a unified context difference, respectively. In the absence of any of these options, `patch` determines the type of difference based on the format of information within the hunk.

For each hunk, `patch` begins to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found, `patch` scans both forwards and backwards at least 1000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan will take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context will be ignored and another scan will be made. Implementations may search more extensively for installation locations.

If no location can be found, `patch` will append the hunk to the reject file. The rejected hunk will be written in context-difference format regardless of the format of the patch file. If the input was a normal or `ed -style` difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they will reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an `ed` diff, the implementation may accomplish the patching by invoking the `ed` command.

EXIT STATUS

The following exit values are returned:

- | | |
|---|--|
| 0 | Successful completion. |
| 1 | One or more lines were written to a reject file. |

patch(1)

>1 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

pathchk(1)

NAME	pathchk – check path names
SYNOPSIS	pathchk [-p] <i>path</i> ...
DESCRIPTION	<p>The <code>pathchk</code> command will check that one or more path names are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation will result). More extensive portability checks are provided by the <code>-p</code> option.</p> <p>By default, <code>pathchk</code> will check each component of each <i>path</i> operand based on the underlying file system. A diagnostic will be written for each <i>path</i> operand that:</p> <ul style="list-style-type: none">■ is longer than <code>PATH_MAX</code> bytes.■ contains any component longer than <code>NAME_MAX</code> bytes in its containing directory■ contains any component in a directory that is not searchable■ contains any character in any component that is not valid in its containing directory. <p>The format of the diagnostic message is not specified, but will indicate the error detected and the corresponding <i>path</i> operand.</p> <p>It will not be considered an error if one or more components of a <i>path</i> operand do not exist as long as a file matching the path name specified by the missing components could be created that does not violate any of the checks specified above.</p>
OPTIONS	<p>The following option is supported:</p> <p><code>-p</code> Instead of performing checks based on the underlying file system, write a diagnostic for each <i>path</i> operand that:</p> <ul style="list-style-type: none">■ is longer than <code>_POSIX_PATH_MAX</code> bytes■ contains any component longer than <code>_POSIX_NAME_MAX</code> bytes■ contains any character in any component that is not in the portable filename character set.
OPERANDS	<p>The following operand is supported:</p> <p><i>path</i> A path to be checked.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>pathchk</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 Using the <code>pathchk</code> command</p> <p>To verify that all paths in an imported data interchange archive are legitimate and unambiguous on the current system:</p> <pre>example% pax -f archive sed -e '/ == ./s///' xargs pathchk if [\$? -eq 0] then pax -r -f archive else</pre>

EXAMPLE 1 Using the pathchk command *(Continued)*

```

        echo Investigate problems before importing files.
        exit 1
    fi

```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the X/Open specification that also supports the pax(1) command:

```

example% find . -print | xargs pathchk -p
if [ $? -eq 0 ]
then
    pax -w -f archive .
else
    echo Portable archive cannot be created.
    exit 1
fi

```

To verify that a user-supplied path names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```

example% case $- in
    *C*)   reset="";;
    *)     reset="set +C"
           set -C;;
esac
test -r "$path" && pathchk "$path.out" &&
rm "$path.out" > "$path.out"
if [ $? -ne 0 ]; then
    printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
    $reset # reset the noclobber option in case a trap
           # on EXIT depends on it
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"

```

The following assumptions are made in this example:

1. PROCESSING represents the code that will be used by the application to use \$path once it is verified that \$path.out will work as intended.
2. The state of the noclobber option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The reset variable is used in this example to restore the initial state.)
3. Note the usage of:

```
rm "$path.out" > "$path.out"
```

- a. The pathchk command has already verified, at this point, that \$path.out will not be truncated.

pathchk(1)

EXAMPLE 1 Using the pathchk command (Continued)

- b. With the `noclobber` option set, the shell will verify that `$path.out` does not already exist before invoking `rm`.
- c. If the shell succeeded in creating `$path.out`, `rm` will remove it so that the application can create the file again in the `PROCESSING` step.
- d. If the `PROCESSING` step wants the file to exist already when it is invoked, the:

```
rm "$path.out" > "$path.out"
```

should be replaced with:

```
> "$path.out"
```

which will verify that the file did not already exist, but leave `$path.out` in place for use by `PROCESSING`.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pathchk`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 All *path* operands passed all of the checks.
- >0 An error occurred.

NAME	pathconv – search FMLI criteria for filename
SYNOPSIS	<p>pathconv [-f] [-v <i>alias</i>]</p> <p>pathconv [-t] [-l] [-nnum] [-v <i>string</i>]</p>
DESCRIPTION	The pathconv function converts an alias to its pathname. By default, it takes the alias as a string from the standard input.
OPTIONS	<p>-f If -f is specified, the full path will be returned (this is the default).</p> <p>-t If -t is specified, pathconv will truncate a pathname specified in <i>string</i> in a format suitable for display as a frame title. This format is a shortened version of the full pathname, created by deleting components of the path from the middle of the string until it is under DISPLAYW — 6 characters in length, and then inserting ellipses (. . .) between the remaining pieces. Ellipses are also used to show truncation at the ends of the strings if necessary, unless the -l option is given.</p> <p>-l If -l is specified, < and > will be used instead of ellipses (. . .) to indicate truncation at the ends of the string generated by the -t option. Using -l allows display of the longest possible string while still notifying users it has been truncated.</p> <p>-nnum If -n is specified, <i>num</i> is the maximum length of the string (in characters) generated by the -t option. The argument <i>num</i> can be any integer from 1 to 255.</p> <p>-valias <i>string</i> If the -v option is used, then <i>alias</i> or <i>string</i> can be specified when pathconv is called. The argument <i>alias</i> must be an alias defined in the <i>alias_file</i> named when <code>fml i</code> was invoked. The argument <i>string</i> can only be used with the -t option and must be a pathname.</p>
EXAMPLES	<p>EXAMPLE 1 A sample that uses pathconv to construct the menu title. It searches for MYPATH in the <i>alias_file</i> named when <code>fml i</code> command.</p> <p>Here is a menu descriptor that uses pathconv to construct the menu title. It searches for MYPATH in the <i>alias_file</i> named when <code>fml i</code> was invoked:</p> <pre>menu='pathconv -v MYPATH/ls' . . .</pre> <p>where there is a line in <i>alias_file</i> that defines MYPATH. For example, MYPATH=\$HOME/bin:/usr/bin.</p> <p>Here is a menu descriptor that takes <i>alias</i> from the standard input.</p> <pre>menu='echo MYPATH/ls pathconv' . . .</pre>

pathconv(1F)

EXAMPLE 1 A sample that uses pathconv to construct the menu title. It searches for MYPATH in the *alias_file* named when fml i command. (Continued)

NAME	pax – portable archive interchange
SYNOPSIS	<pre> pax [-cdnv] [-f <i>archive</i>] [-s <i>replstr</i>] ... [<i>pattern</i>...] pax -r [-cdiknuv] [-f <i>archive</i>] [-o <i>options</i>...] [-p <i>string</i>] ... [-s <i>replstr</i>] ... [<i>pattern</i>...] pax -w [-dituvX@] [-b <i>blocksize</i>] [-a] [-f <i>archive</i>] [-o <i>options</i>] ... [-s <i>replstr</i>] ... [-x <i>format</i>] [<i>file</i>...] pax -r -w [-diklntuvX@] [-p <i>string</i>] ... [-s <i>replstr</i>] ... [<i>file</i>...] <i>directory</i> </pre>
DESCRIPTION	The pax command reads, writes and writes lists of the members of archive files and copy directory hierarchies. A variety of archive formats are supported. See the -x <i>format</i> option.
Modes of Operations	<p>The action to be taken depends on the presence of the -r and -w options. The four combinations of -r and -w are referred to as the four modes of operation: list, read, write, and copy modes, corresponding respectively to the four forms shown in the SYNOPSIS.</p> <p>list In list mode (when neither -r nor -w are specified), pax writes the names of the members of the archive file read from the standard input, with path names matching the specified patterns, to standard output. If a named file has extended attributes, the extended attributes are also listed. If a named file is of type directory, the file hierarchy rooted at that file will be written out as well.</p> <p>read In read mode (when -r is specified, but -w is not), pax extracts the members of the archive file read from the standard input, with path names matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file will be extracted as well. The extracted files is created relative to the current file hierarchy.</p> <p> The ownership, access and modification times, and file mode of the restored files are discussed under the -p option.</p> <p>write In write mode (when -w is specified, but -r is not), pax writes the contents of the file operands to the standard output in an archive format. If no <i>file</i> operands are specified, a list of files to copy, one per line, will be read from the standard input. A file of type directory will include all of the files in the file hierarchy rooted at the file.</p> <p>copy In copy mode (when both -r and -w are specified), pax copies the <i>file</i> operands to the destination directory.</p> <p> If no <i>file</i> operands are specified, a list of files to copy, one per line, will be read from the standard input. A file of type directory will include all of the files in the file hierarchy rooted at the file.</p>

pax(1)

The effect of the copy is as if the copied files were written to an archive file and then subsequently extracted, except that there may be hard links between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. It is an error if *directory* does not exist, is not writable by the user, or is not a directory.

In read or copy modes, if intermediate directories are necessary to extract an archive member, pax will perform actions equivalent to the `mkdir(2)` function, called with the following arguments:

- the intermediate directory used as the *path* argument
- the octal value of 777 or `rwx` (read, write, and execute permissions) as the *mode* argument (see `chmod(1)`).

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, pax will write a diagnostic message to standard error for each one that did not match and exit with a non-zero exit status.

The supported archive formats are automatically detected on input. The default output archive format is `tar(1)`.

If the selected archive format supports the specification of linked files, it is an error if these files cannot be linked when the archive is extracted. Any of the various names in the archive that represent a file can be used to select the file for extraction.

OPTIONS

The following options are supported:

- | | |
|---------------------|--|
| -r | Reads an archive file from standard input. |
| -w | Writes files to the standard output in the specified archive format. |
| -a | Appends files to the end of the archive. This option will not work for some archive devices, such as 1/4-inch streaming tapes and 8mm tapes. |
| -b <i>blocksize</i> | Blocks the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking is automatically determined on input. Portable applications must not specify a <i>blocksize</i> value larger than 32256. Default blocking when creating archives depends on the archive format. See the <code>-x</code> option below. |
| -c | Matches all file or archive members except those specified by the <i>pattern</i> or <i>file</i> operands. |
| -d | Causes files of type directory being copied or archived or archive members of type directory being extracted to match only the file or archive member itself and not the file hierarchy rooted at the file. |

<i>-f archive</i>	Specifies the path name of the input or output archive, overriding the default standard input (in list or read modes) or standard output (write mode).
<i>-i</i>	Interactively renames files or archive members. For each archive member matching a <i>pattern</i> operand or file matching a <i>file</i> operand, a prompt will be written to the file <code>/dev/tty</code> . The prompt will contain the name of the file or archive member. A line will then be read from <code>/dev/tty</code> . If this line is blank, the file or archive member will be skipped. If this line consists of a single period, the file or archive member will be processed with no modification to its name. Otherwise, its name will be replaced with the contents of the line. The <code>pax</code> command will immediately exit with a non-zero exit status if end-of-file is encountered when reading a response or if <code>/dev/tty</code> cannot be opened for reading and writing.
<i>-k</i>	Prevents the overwriting of existing files.
<i>-l</i>	Links files. In copy mode, hard links will be made between the source and destination file hierarchies whenever possible.
<i>-n</i>	Selects the first archive member that matches each <i>pattern</i> operand. No more than one archive member will be matched for each pattern, although members of type <i>directory</i> will still match the file hierarchy rooted at that file.
<i>-o options</i>	Reserved for special format-specific options.
<i>-p string</i>	Specifies one or more file characteristic options (privileges). The <i>string</i> option-argument must be a string specifying file characteristics to be retained or discarded on extraction. The string consists of the specification characters <code>a</code> , <code>e</code> , <code>m</code> , <code>o</code> , and <code>p</code> . Multiple characteristics can be concatenated within the same string and multiple <code>-p</code> options can be specified. The meaning of the specification characters are as follows:
<code>a</code>	Does not preserve file access times.
<code>e</code>	Preserves the user ID, group ID, file mode bits, access time, and modification time.
<code>m</code>	Does not preserve file modification times.
<code>o</code>	Preserves the user ID and group ID.
<code>p</code>	Preserves the file mode bits. Other, implementation-dependent file-mode attributes may be preserved.

pax(1)

	<p>In the preceding list, “preserve” indicates that an attribute stored in the archive will be given to the extracted file, subject to the permissions of the invoking process. Otherwise, the attribute will be determined as part of the normal file creation action.</p> <p>If neither the <code>e</code> nor the <code>o</code> specification character is specified, or the user ID and group ID are not preserved for any reason, <code>pax</code> will not set the <code>setuid</code> and <code>setgid</code> bits of the file mode.</p> <p>If the preservation of any of these items fails for any reason, <code>pax</code> will write a diagnostic message to standard error. Failure to preserve these items will affect the final exit status, but will not cause the extracted file to be deleted.</p> <p>If file-characteristic letters in any of the <i>string</i> option-arguments are duplicated or conflict with each other, the ones given last will take precedence. For example, if <code>-p eme</code> is specified, file modification times will be preserved.</p>
<code>-s replstr</code>	<p>Modifies file or archive member names named by <i>pattern</i> or <i>file</i> operands according to the substitution expression <i>replstr</i>, which is based on the <code>ed(1) s</code> (substitution) command, using the regular expression syntax on the <code>regex(5)</code> manual page. The concepts of “address” and “line” are meaningless in the context of the <code>pax</code> command, and must not be supplied. The format is:</p> <pre>-s / old/new/ [gp]</pre> <p>where, as in <code>ed</code>, <i>old</i> is a basic regular expression and <i>new</i> can contain an ampersand (&) or a <code>\n</code> backreference, where <i>n</i> is a digit. The <i>old</i> string also is permitted to contain newline characters.</p> <p>Any non-null character can be used as a delimiter (/ shown here). Multiple <code>-s</code> expressions can be specified; the expressions will be applied in the order specified, terminating with the first successful substitution. The optional trailing <code>g</code> is as defined in the <code>ed</code> command. The optional trailing <code>p</code> causes successful substitutions to be written to standard error. File or archive member names that substitute to the empty string are ignored when reading and writing archives.</p>
<code>-t</code>	<p>Causes the access times of the archived files to be the same as they were before being read by <code>pax</code>.</p>
<code>-u</code>	<p>Ignores files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name.</p>

	read mode	An archive member with the same name as a file in the file system will be extracted if the archive member is newer than the file.
	write mode	An archive file member with the same name as a file in the file system will be superseded if the file is newer than the archive member.
	copy mode	The file in the destination hierarchy will be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.
-v		In list mode, produces a verbose table of contents (see <i>Standard Output</i>). Otherwise, writes archive member path names and extended attributes to standard error (see <i>Standard Error</i>).
-x <i>format</i>		Specifies the output archive format. The <code>pax</code> command recognizes the following formats:
	cpio	<p>The extended <code>cpio(1)</code> interchange format. See the IEEE 1003.1(1990) specifications. The default <i>blocksize</i> for this format for character special archive files is 5120. Implementations support all <i>blocksize</i> values less than or equal to 32256 that are multiples of 512.</p> <p>This archive format allows files with UIDs and GIDs up to 262143 to be stored in the archive. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.</p>
	ustar	<p>The extended <code>tar(1)</code> interchange format. See the IEEE 1003.1(1990) specifications. The default <i>blocksize</i> for this format for character special archive files is 10240. Implementations support all <i>blocksize</i> values less than or equal to 32256 that are multiples of 512.</p> <p>Any attempt to append to an archive file in a format different from the existing archive format will cause <code>pax</code> to exit immediately with a non-zero exit status.</p> <p>This archive format allows files with UIDs and GIDs up to 2097151 to be stored in the archive. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.</p>

pax(1)

	<code>xustar</code>	Similar to <code>ustar</code> . Will also allow archiving and extracting files whose size is greater than 8GB; whose UID, GID, <code>devmajor</code> , or <code>devminor</code> values are greater than 2097151; whose path (including filename) is greater than 255 characters; or whose linkname is greater than 100 characters. This option should not be used if the archive is to be extracted by an archiver that cannot handle the larger values.
<code>-X</code>		When traversing the file hierarchy specified by a path name, <code>pax</code> will not descend into directories that have a different device ID (<code>st_dev</code> , see <code>stat(2)</code>).
<code>-@</code>		When traversing the file hierarchy specified by a path name, <code>pax</code> will descend into the attribute directory for any file with extended attributes. Extended attributes go into the archive as special files. When this flag is used during file extraction, any extended attributes associated with a file being extracted are also extracted. Extended attribute files can only be extracted from an archive as part of a normal file extract. Attempts to explicitly extract attribute records are ignored.
		The options that operate on the names of files or archive members (<code>-c</code> , <code>-i</code> , <code>-n</code> , <code>-s</code> , <code>-u</code> and <code>-v</code>) interact as follows. In read mode, the archive members are selected based on the user-specified <i>pattern</i> operands as modified by the <code>-c</code> , <code>-n</code> and <code>-u</code> options. Then, any <code>-s</code> and <code>-i</code> options will modify, in that order, the names of the selected files. The <code>-v</code> option will write names resulting from these modifications.
		In write mode, the files are selected based on the user-specified path names as modified by the <code>-n</code> and <code>-u</code> options. Then, any <code>-s</code> and <code>-i</code> options will, in that order, modify the names of these selected files. The <code>-v</code> option will write names resulting from these modifications.
		If both the <code>-u</code> and <code>-n</code> options are specified, <code>pax</code> does not consider a file selected unless it is newer than the file to which it is compared.
OPERANDS		The following operands are supported:
	<i>directory</i>	The destination directory path name for copy mode.
	<i>file</i>	A path name of a file to be copied or archived.
	<i>pattern</i>	A pattern matching one or more path names of archive members. A pattern must conform to the pattern matching notation found on the <code>fnmatch(5)</code> manual page. The default, if no <i>pattern</i> is specified, is to select all members in the archive.
Standard Output		In write mode, if <code>-f</code> is not specified, the standard output will be the archive formatted according to <code>cpio</code> or <code>ustar</code> . (See <code>-x</code> format.)

In list mode, the table of contents of the selected archive members will be written to standard output using the following format:

```
"%s\n" pathname
```

If the `-v` option is specified in list mode, the table of contents of the selected archive members will be written to standard output using the following formats:

For path names representing hard links to previous members of the archive:

```
"%s==%s\n" ls -l listing, linkname
```

For all other path names:

```
pathname "%s\n" ls -l listing
```

where `ls -l listing` is the format specified by the `ls` command with the `-l` option.

When writing path names in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of blank-character-separated fields will be written.

In list mode, standard output will not be buffered more than a line at a time.

Standard Error If `-v` is specified in read, write or copy modes, `pax` will write the path names it processes to the standard error output using the following format:

```
"%s\n" pathname
```

These path names will be written as soon as processing is begun on the file or archive member, and will be flushed to standard error. The trailing newline character, which will not be buffered, will be written when the file has been read or written.

If the `-s` option is specified, and the replacement string has a trailing `p`, substitutions will be written to standard error in the following format:

```
"%s>>%s\n" original pathname, new pathname
```

In all operating modes of `pax`, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes and media parts as well as other diagnostic messages may be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in path names or linknames are written.

ERRORS If `pax` cannot create a file or a link when reading an archive or cannot find a file when writing an archive, or cannot preserve the user ID, group ID, or file mode when the `-p` option is specified, a diagnostic message will be written to standard error and a non-zero exit status will be returned, but processing will continue. In the case where `pax` cannot create a link to a file, `pax` will not, by default, create a second copy of the file.

pax(1)

If the extraction of a file from an archive is prematurely terminated by a signal or error, `pax` may have only partially extracted the file or (if the `-n` option was not specified) may have extracted a file of the same name as that specified by the user, but which is not the file the user wanted. Additionally, the file modes of extracted directories may have additional bits from the read, write, execute mask set as well as incorrect modification and access times.

USAGE The `-p` (privileges) option was invented to reconcile differences between historical `tar(1)` and `cpio(1)` implementations. In particular, the two utilities use `-m` in diametrically opposed ways. The `-p` option also provides a consistent means of extending the ways in which future file attributes can be addressed, such as for enhanced security systems or high-performance files. Although it may seem complex, there are really two modes that will be most commonly used:

- `-p e` “Preserve everything”. This would be used by the historical superuser, someone with all the appropriate privileges, to preserve all aspects of the files as they are recorded in the archive. The `e` flag is the sum of `o` and `p`, and other implementation-dependent attributes.
- `-p p` “Preserve” the file mode bits. This would be used by the user with regular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are offered to disable these and use the time of extraction.

See `largefile(5)` for the description of the behavior of `pax` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Copying the contents of the current directory

The following command:

```
example% pax -w -f /dev/rmt/1m .
```

copies the contents of the current directory to tape drive 1, medium density. (This assumes historical System V device naming procedures. The historical BSD device name would be `/dev/rmt9`).

EXAMPLE 2 Copying the directory hierarchy

The following commands:

```
example% mkdir newdir
example% pax -rw olddir newdir
```

copy the `olddir` directory hierarchy to `newdir`.

EXAMPLE 3 Reading an archive extracted relative to the current directory

The following command:

```
example% pax -r -s ',^/*usr/*,,,' -f a.pax
```

reads the archive `a.pax`, with all files rooted in `/usr` in the archive extracted relative to the current directory.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pax`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

`LC_COLLATE` Determine the locale for the behaviour of ranges, equivalence classes, and multi-character collating elements used in the pattern matching expressions for the *pattern* operand, the basic regular expression for the `-s` option, and the extended regular expression defined for the `yesexpr` locale keyword in the `LC_MESSAGES` category.

EXIT STATUS

The following exit values are returned:

0 All files were processed successfully.
>0 An error occurred.

perlsolaris	Perl notes for Solaris

(If you're intending to read these straight through for the first time, the suggested order will tend to reduce the number of forward references.)

The manpages listed above are installed in the `/usr/perl5/man/` directory.

Extensive additional documentation for Perl modules is available. This additional documentation is also in the `/usr/local/lib/perl5/man` directory. Some of this additional documentation is distributed as standard with Perl, but you'll also find documentation for any customer-installed third-party modules there.

Notice that running `catman(1M)` on the Perl manual pages is not supported. For other Solaris-specific details, see the NOTES section below.

perl(1)

You can also use the supplied `/usr/perl5/bin/perl5doc` script to view Perl information.

If something strange has gone wrong with your program and you're not sure where you should look for help, try the `-w` switch first. It will often point out exactly where the trouble is.

Perl is a language optimized for scanning arbitrary text files, extracting information from those text files, and printing reports based on that information. It's also a good language for many system management tasks. The language is intended to be practical (easy to use, efficient, complete) rather than beautiful (tiny, elegant, minimal).

Perl combines (in the author's opinion, anyway) some of the best features of `C`, `sed`, `awk`, and `sh`, so people familiar with those languages should have little difficulty with it. (Language historians will also note some vestiges of `csh`, Pascal, and even BASIC-PLUS.) Expression syntax corresponds quite closely to C expression syntax. Unlike most Unix utilities, Perl does not arbitrarily limit the size of your data--if you've got the memory, Perl can slurp in your whole file as a single string. Recursion is of unlimited depth. And the tables used by hashes (sometimes called "associative arrays") grow as necessary to prevent degraded performance. Perl can use sophisticated pattern matching techniques to scan large amounts of data quickly. Although optimized for scanning text, Perl can also deal with binary data, and can make dbm files look like hashes. Setuid Perl scripts are safer than C programs through a dataflow tracing mechanism that prevents many stupid security holes.

If you have a problem that would ordinarily use `sed` or `awk` or `sh`, but it exceeds their capabilities or must run a little faster, and you don't want to write the silly thing in `C`, then Perl may be for you. There are also translators to turn your `sed` and `awk` scripts into Perl scripts.

But wait, there's more...

Begun in 1993 (see the `perlh1st` man page), Perl version 5 is nearly a complete rewrite that provides the following additional benefits:

- Modularity and reusability using innumerable modules
Described in the `perlmod` man page, the `perlmodlib` man page, and the `perlmodinstall` man page.
- Embeddable and Extensible
Described in the `perlembed` man page, the `perlxs` man page, the `perlcall` man page, the `perlguits` man page, and the `xsubpp` man page.
- Roll-your-own magic variables
(Including multiple simultaneous DBM implementations) Described in the `perltie` man page and the `AnyDBM_File` man page.
- Subroutines can now be overridden, autoloading, and prototyped. Described in the `perlsub` man page.

- Arbitrarily nested data structures and anonymous functions. Described in the `perlreftut` man page, the `perlref` man page, the `perldsc` man page, and the `perl101` man page.
- Object-oriented programming
Described in the `perlobj` man page, the `perltoot` man page, and the `perlbot` man page.
- Compilability into C code or Perl bytecode
Described in the `B` man page and the `B::Bytecode` man page.
- Support for light-weight processes (threads)
Described in the `perlthrtut` man page and the `Thread` man page. Notice that the Perl shipped as part of Solaris does NOT have threads support enabled. If you require threads support, you should build and install your own Perl version (see the NOTES section below).
- Support for internationalization, localization, and Unicode. Described in the `perllocale` man page and the `utf8` man page.
- Lexical scoping
Described in the `perlsub` man page.
- Regular expression enhancements
Described in the `perlre` man page, with additional examples in the `perlop` man page.
- Enhanced debugger and interactive Perl environment, with integrated editor support. Described in the `perldebug` man page.
- POSIX 1003.1 compliant
Described in the `POSIX` man page.

Okay, that's *definitely* enough hype.

AVAILABILITY Perl is available for most operating systems, including virtually all Unix-like platforms. See the Supported Platforms entry in the `perlport` man page for a listing.

ENVIRONMENT The Perl shipped with Solaris is installed under `/usr/perl5` rather than the default `/usr/local` location. This is so that it can coexist with a customer-installed Perl in the default `/usr/local` location.

Any additional modules that you choose to install will be placed in the `/usr/perl5/site_perl/5.6.1` directory. The `/usr/perl5/vendor_perl` directory is reserved for SMI-provided modules.

Notice that the Perl utility scripts such as `perldoc` and `perlbug` are in the `/usr/perl5/bin` directory, so if you wish to use them you need to include `/usr/perl5/bin` in your `PATH` environment variable.

See also the `perlrun` man page.

perl(1)

AUTHOR Larry Wall , with the help of oodles of other folks.

DIAGNOSTICS The "use warnings" pragma (and the `-w` switch) produces some lovely diagnostics.
See the `perldiag` man page for explanations of all Perl's diagnostics. The "use diagnostics" pragma automatically turns Perl's normally terse warnings and errors into these longer forms.

Compilation errors will tell you the line number of the error, with an indication of the next token or token type that was to be examined. (In a script passed to Perl via `-e` switches, each `-e` is counted as one line.)

Setuid scripts have additional constraints that can produce error messages such as "Insecure dependency". See the `perlsec` man page.

Did we mention that you should definitely consider using the `-w` switch?

NOTES Solaris 9 contains two versions of Perl, 5.005_03 (as shipped in Solaris 8) and 5.6.1. `/bin/perl` is a link to the 5.6.1 interpreter, and `/usr/perl5/bin` is a link to the `/usr/perl5/5.6.1/bin` directory. It is likely that version 5.005_03 will be removed in a future release of Solaris.

Perl 5.6.1 has been built to be largefile-aware and to use 64-bit integers, although the interpreter itself is a 32-bit application (LP32). To view detailed configuration information, use `perl -V` and `perlbug -dv`.

Notice that 5.6.1 is binary incompatible with the 5.005_03 version, primarily due to the addition of largefile/64-bit integer support. Existing customer-installed XSUB-based modules will require recompilation, and non-XSUB modules will require reinstallation.

If you have any applications that require 5.005_03, you should make sure they explicitly use `/usr/perl5/5.005_03/bin/perl`. It is also possible to make 5.005_03 the default Perl version, although this is not recommended. The steps for this would be (as root):

```
# rm /usr/bin/perl
# ln -s ../perl5/5.00503/bin/perl /usr/bin/perl
# rm /usr/perl5/bin
# ln -s ../5.00503/bin /usr/perl5/bin
# rm /usr/perl5/man
# ln -s ../5.00503/man /usr/perl5/man
# rm /usr/perl5/pod
# ln -s ../5.00503/pod /usr/perl5/pod
```

If you wish to build and install your own version of Perl, you should NOT remove the 5.6.1 version of perl under `/usr/perl5`, as it is required by several system utilities. If you do not want to use the 5.005_03 version, you may remove that if you wish. The Perl package names are as follows:

```
SUNWpl5u      Perl 5.6.1
SUNWpl5p      Perl 5.6.1 (POD Documentation)
SUNWpl5m      Perl 5.6.1 (Manual pages)
SUNWop15u     Perl 5.005_03
SUNWop15p     Perl 5.005_03 (POD Documentation)
SUNWop15m     Perl 5.005_03 (Manual pages)
```

The Perl motto is "There's more than one way to do it." Divining how many more is left as an exercise to the reader.

The three principal virtues of a programmer are Laziness, Impatience, and Hubris. See the Camel Book for why.

BUGS The `-w` switch is not mandatory.

Perl is at the mercy of your machine's definitions of various operations such as type casting, `atof()`, and floating-point output with `sprintf()`.

If your stdio requires a seek or eof between reads and writes on a particular stream, so does Perl. (This doesn't apply to `sysread()` and `syswrite()`.)

perl(1)

While none of the built-in data types have any arbitrary size limits (apart from memory size), there are still a few arbitrary limits: a given variable name may not be longer than 251 characters. Line numbers displayed by diagnostics are internally stored as short integers, so they are limited to a maximum of 65535 (higher numbers usually being affected by wraparound).

You may mail your bug reports (be sure to include full configuration information as output by the `myconfig` program in the Perl source tree, or by `perl -V`) to [`<perlbug@perl.org>`](mailto:perlbug@perl.org).

Perl actually stands for Pathologically Eclectic Rubbish Lister, but don't tell anyone I said that.

NAME	pfexec, pfsh, pfcsh, pfksh – execute a command in a profile				
SYNOPSIS	<pre> /usr/bin/pfexec <i>command</i> /usr/bin/pfsh [<i>options</i>] [<i>argument</i> ...] /usr/bin/pfcsh [<i>options</i>] [<i>argument</i> ...] /usr/bin/pfksh [<i>options</i>] [<i>argument</i> ...] </pre>				
DESCRIPTION	<p>The pfexec program is used to execute commands with the attributes specified by the user's profiles in the exec_attr(4) database. It is invoked by the profile shells, pfsh, pfcsh, and pfksh which are linked to the Bourne shell, C shell, and Korn shell, respectively.</p> <p>Profiles are searched in the order specified in the user's entry in the user_attr(4) database. If the same command appears in more than one profile, the profile shell uses the first matching entry.</p>				
USAGE	<p>pfexec is used to execute commands with predefined process attributes, such as specific user or group IDs.</p> <p>Refer to the sh(1), csh(1), and ksh(1) man pages for complete usage descriptions of the profile shells.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

pg(1)

NAME	pg – files perusal filter for CRTs
SYNOPSIS	pg [- <i>number</i>] [-p <i>string</i>] [-cefnrs] [+ <i>linenumber</i>] [+/ <i>pattern</i> /] [<i>filename...</i>]
DESCRIPTION	<p>The pg command is a filter that allows the examination of <i>filenames</i> one screenful at a time on a CRT. If the user types a RETURN, another page is displayed; other possibilities are listed below.</p> <p>This command is different from previous paginators in that it allows you to back up and review something that has already passed. The method for doing this is explained below.</p> <p>To determine terminal attributes, pg scans the <code>terminfo(4)</code> data base for the terminal type specified by the environment variable <code>TERM</code>. If <code>TERM</code> is not defined, the terminal type <code>dumb</code> is assumed.</p>
OPTIONS	<p><i>-number</i> An integer specifying the size (in lines) of the window that pg is to use instead of the default. (On a terminal containing 24 lines, the default window size is 23).</p> <p><i>-p string</i> pg uses <i>string</i> as the prompt. If the prompt string contains a <code>%d</code>, the first occurrence of <code>%d</code> in the prompt will be replaced by the current page number when the prompt is issued. The default prompt string is <code>:"</code>.</p> <p><i>-c</i> Home the cursor and clear the screen before displaying each page. This option is ignored if <code>clear_screen</code> is not defined for this terminal type in the <code>terminfo(4)</code> data base.</p> <p><i>-e</i> pg does <i>not</i> pause at the end of each file.</p> <p><i>-f</i> Normally, pg splits lines longer than the screen width, but some sequences of characters in the text being displayed (for instance, escape sequences for underlining) generate undesirable results. The <i>-f</i> option inhibits pg from splitting lines.</p> <p><i>-n</i> Normally, commands must be terminated by a <code><newline></code> character. This option causes an automatic end of command as soon as a command letter is entered.</p> <p><i>-r</i> Restricted mode. The shell escape is disallowed. pg prints an error message but does not exit.</p> <p><i>-s</i> pg prints all messages and prompts in the standard output mode (usually inverse video).</p> <p><i>+linenumber</i> Start up at <i>linenumber</i>.</p> <p><i>+/<i>pattern</i>/</i> Start up at the first line containing the regular expression pattern.</p>
OPERANDS	The following operands are supported:

Commands	<p><i>filename</i> A path name of a text file to be displayed. If no <i>filename</i> is given, or if it is <code>-</code>, the standard input is read.</p> <p>The responses that may be typed when <code>pg</code> pauses can be divided into three categories: those causing further perusal, those that search, and those that modify the perusal environment.</p> <p>Commands that cause further perusal normally take a preceding <i>address</i>, an optionally signed number indicating the point from which further text should be displayed. This <i>address</i> is interpreted in either pages or lines depending on the command. A signed <i>address</i> specifies a point relative to the current page or line, and an unsigned <i>address</i> specifies an address relative to the beginning of the file. Each command has a default address that is used if none is provided.</p> <p>The perusal commands and their defaults are as follows:</p> <p>(+1)<<i>newline</i>> or <<i>blank</i>> This causes one page to be displayed. The address is specified in pages.</p> <p>(+1) 1 With a relative address this causes <code>pg</code> to simulate scrolling the screen, forward or backward, the number of lines specified. With an absolute address this command prints a screenful beginning at the specified line.</p> <p>(+1) d or ^D Simulates scrolling half a screen forward or backward.</p> <p><i>i</i>f Skip <i>i</i> screens of text.</p> <p><i>i</i>z Same as <<i>newline</i>> except that <i>i</i>, if present, becomes the new default number of lines per screenful.</p> <p>The following perusal commands take no <i>address</i>.</p> <p>. or ^L Typing a single period causes the current page of text to be redisplayed.</p> <p>§ Displays the last windowful in the file. Use with caution when the input is a pipe.</p> <p>The following commands are available for searching for text patterns in the text. The regular expressions are described on the <code>regex(5)</code> manual page. They must always be terminated by a <<i>newline</i>>, even if the <code>-n</code> option is specified.</p> <p><i>i</i>/<i>pattern</i>/ Search forward for the <i>i</i>th (default <i>i</i>=1) occurrence of <i>pattern</i>. Searching begins immediately after the current page and continues to the end of the current file, without wrap-around.</p> <p><i>i</i>^<i>pattern</i>^ Search backwards for the <i>i</i>th (default <i>i</i>=1) occurrence of <i>pattern</i>. Searching begins immediately before the current page and continues to the beginning of the current file, without</p>
-----------------	--

pg(1)

wrap-around. The ^ notation is useful for Adds 100 terminals which will not properly handle the ?.

After searching, pg will normally display the line found at the top of the screen. This can be modified by appending m or b to the search command to leave the line found in the middle or at the bottom of the window from now on. The suffix t can be used to restore the original situation.

The user of pg can modify the environment of perusal with the following commands:

<i>in</i>	Begin perusing the <i>i</i> th next file in the command line. The <i>i</i> is an unsigned number, default value is 1.
<i>ip</i>	Begin perusing the <i>i</i> th previous file in the command line. <i>i</i> is an unsigned number, default is 1.
<i>iw</i>	Display another window of text. If <i>i</i> is present, set the window size to <i>i</i> .
<i>s filename</i>	Save the input in the named file. Only the current file being perused is saved. The white space between the <i>s</i> and <i>filename</i> is optional. This command must always be terminated by a <i><newline></i> , even if the -n option is specified.
<i>h</i>	Help by displaying an abbreviated summary of available commands.
<i>q</i> or <i>Q</i>	Quit pg.
<i>!command</i>	<i>Command</i> is passed to the shell, whose name is taken from the SHELL environment variable. If this is not available, the default shell is used. This command must always be terminated by a <i><newline></i> , even if the -n option is specified.

At any time when output is being sent to the terminal, the user can hit the quit key (normally CTRL-\) or the interrupt (break) key. This causes pg to stop sending output, and display the prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost when this is done, because any characters waiting in the terminal's output queue are flushed when the quit signal occurs.

If the standard output is not a terminal, then pg acts just like cat(1), except that a header is printed before each file (if there is more than one).

Large File Behavior

See largefile(5) for the description of the behavior of pg when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

EXAMPLES

EXAMPLE 1 An example of the pg command.

The following command line uses pg to read the system news:

```
example% news | pg -p "(Page %d) :"
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pg`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The following environment variables affect the execution of `pg`:

<code>COLUMNS</code>	Determine the horizontal screen size. If unset or <code>NULL</code> , use the value of <code>TERM</code> , the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
<code>LINES</code>	Determine the number of lines to be displayed on the screen. If unset or <code>NULL</code> , use the value of <code>TERM</code> , the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
<code>SHELL</code>	Determine the name of the command interpreter executed for a <code>!command</code> .
<code>TERM</code>	Determine terminal attributes. Optionally attempt to search a system-dependent database, keyed on the value of the <code>TERM</code> environment variable. If no information is available, a terminal incapable of cursor-addressable movement is assumed.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

FILES

<code>/tmp/pg*</code>	temporary file when input is from a pipe
<code>/usr/share/lib/terminfo/?/*</code>	terminal information database

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

SEE ALSO

`cat(1)`, `grep(1)`, `more(1)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `regex(5)`

NOTES

While waiting for terminal input, `pg` responds to `BREAK`, `CTRL-C`, and `CTRL-\` by terminating execution. Between prompts, however, these signals interrupt `pg`'s current task and place the user in prompt mode. These should be used with caution when input is being read from a pipe, since an interrupt is likely to terminate the other commands in the pipeline.

The terminal `/`, `^`, or `?` may be omitted from the searching commands.

pg(1)

If terminal tabs are not set every eight positions, undesirable results may occur.

When using `pg` as a filter with another command that changes the terminal I/O options, terminal settings may not be restored correctly.

NAME	pgrep, pkill – find or signal processes by name and other attributes
SYNOPSIS	<pre> pgrep [-flvx] [-n -o] [-d <i>delim</i>] [-P <i>ppidlist</i>] [-g <i>pgrplist</i>] [-s <i>sidlist</i>] [-u <i>euidlist</i>] [-U <i>uidlist</i>] [-G <i>gidlist</i>] [-J <i>projidlist</i>] [-t <i>termlist</i>] [-T <i>taskidlist</i>] [<i>pattern</i>] pkill [-<i>signal</i>] [-fvx] [-n -o] [-P <i>ppidlist</i>] [-g <i>pgrplist</i>] [-s <i>sidlist</i>] [-u <i>euidlist</i>] [-U <i>uidlist</i>] [-G <i>gidlist</i>] [-J <i>projidlist</i>] [-t <i>termlist</i>] [-T <i>taskidlist</i>] [<i>pattern</i>] </pre>
DESCRIPTION	<p>The <code>pgrep</code> utility examines the active processes on the system and reports the process IDs of the processes whose attributes match the criteria specified on the command line. Each process ID is printed as a decimal value and is separated from the next ID by a delimiter string, which defaults to a newline. For each attribute option, the user can specify a set of possible values separated by commas on the command line. For example,</p> <pre>pgrep -G other,daemon</pre> <p>matches processes whose real group ID is <code>other</code> OR <code>daemon</code>. If multiple criteria options are specified, <code>pgrep</code> matches processes whose attributes match the logical AND of the criteria options. For example,</p> <pre>pgrep -G other,daemon -U root,daemon</pre> <p>matches processes whose attributes are:</p> <p>(real group ID is <code>other</code> OR <code>daemon</code>) AND (real user ID is <code>root</code> OR <code>daemon</code>)</p> <p><code>pkill</code> functions identically to <code>pgrep</code>, except that each matching process is signaled as if by <code>kill(1)</code> instead of having its process ID printed. A signal name or number may be specified as the first command line option to <code>pkill</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -d <i>delim</i> Specifies the output delimiter string to be printed between each matching process ID. If no <code>-d</code> option is specified, the default is a newline character. The <code>-d</code> option is only valid when specified as an option to <code>pgrep</code>. -f The regular expression <i>pattern</i> should be matched against the full process argument string (obtained from the <code>pr_psargs</code> field of the <code>/proc/<i>nnnnn</i>/psinfo</code> file). If no <code>-f</code> option is specified, the expression is matched only against the name of the executable file (obtained from the <code>pr_fname</code> field of the <code>/proc/<i>nnnnn</i>/psinfo</code> file). -g <i>pgrplist</i> Matches only processes whose process group ID is in the given list. If group 0 is included in the list, this is interpreted as the process group ID of the <code>pgrep</code> or <code>pkill</code> process.

pgrep(1)

-G <i>gidlist</i>	Matches only processes whose real group ID is in the given list. Each group ID may be specified as either a group name or a numerical group ID.
-J <i>projidlist</i>	Matches only processes whose project ID is in the given list. Each project ID may be specified as either a project name or a numerical project ID.
-l	Long output format. Prints the process name along with the process ID of each matching process. The process name is obtained from the <code>pr_psargs</code> or <code>pr_fname</code> field, depending on whether the <code>-f</code> option was specified (see above). The <code>-l</code> option is only valid when specified as an option to <code>pgrep</code> .
-n	Matches only the newest (most recently created) process that meets all other specified matching criteria. Cannot be used with option <code>-o</code> .
-o	Matches only the oldest (earliest created) process that meets all other specified matching criteria. Cannot be used with option <code>-n</code> .
-P <i>ppidlist</i>	Matches only processes whose parent process ID is in the given list.
-s <i>sidlist</i>	Matches only processes whose process session ID is in the given list. If ID 0 is included in the list, this is interpreted as the session ID of the <code>pgrep</code> or <code>pkill</code> process.
-t <i>termlist</i>	Matches only processes which are associated with a terminal in the given list. Each terminal is specified as the suffix following <code>"/dev/"</code> of the terminal's device path name in <code>/dev</code> . For example, <code>term/a</code> or <code>pts/0</code> .
-T <i>taskidlist</i>	Matches only processes whose task ID is in the given list. If ID 0 is included in the list, this is interpreted as the task ID of the <code>pgrep</code> or <code>pkill</code> process.
-u <i>uidlist</i>	Matches only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
-U <i>uidlist</i>	Matches only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
-v	Reverses the sense of the matching. Matches all processes <i>except</i> those which meet the specified matching criteria.
-x	Considers only processes whose argument string or executable file name <i>exactly</i> matches the specified <i>pattern</i> to be matching processes. The pattern match is considered to be exact when all characters in the process argument string or executable file name match the pattern.

-signal Specifies the signal to send to each matched process. If no signal is specified, SIGTERM is sent by default. The value of *signal* can be one of the symbolic names defined in signal(3HEAD) without the SIG prefix, or the corresponding signal number as a decimal value. The *-signal* option is only valid when specified as the first option to `kill`.

OPERANDS The following operand is supported:

pattern Specifies an Extended Regular Expression (ERE) pattern to match against either the executable file name or full process argument string. See regex(5) for a complete description of the ERE syntax.

EXAMPLES **EXAMPLE 1** Obtaining a process ID

Obtain the process ID of `sendmail`:

```
example% pgrep -x -u root sendmail
283
```

EXAMPLE 2 Terminating a process

Terminate the most recently created `xterm`:

```
example% pkill -n xterm
```

EXIT STATUS The following exit values are returned:

- 0 One or more processes were matched.
- 1 No processes were matched.
- 2 Invalid command line options were specified.
- 3 A fatal error occurred.

FILES `/proc/nnnnn/psinfo` Process information files

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `kill(1)`, `proc(1)`, `ps(1)`, `truss(1)`, `kill(2)`, `signal(3HEAD)`, `proc(4)`, `attributes(5)`, `regex(5)`

NOTES Both utilities match the ERE *pattern* argument against either the `pr_fname` or `pr_psargs` fields of the `/proc/nnnnn/psinfo` files. The lengths of these strings are limited according to definitions in `<sys/procfs.h>`. Patterns which can match strings longer than the current limits may fail to match the intended set of processes.

pgrep(1)

If the *pattern* argument contains ERE meta-characters which are also shell meta-characters, it may be necessary to enclose the pattern with appropriate shell quotes.

Defunct processes are never matched by either `pgrep` or `pskill`.

The current `pgrep` or `pskill` process will never consider itself a potential match.

NAME	pkginfo – display software package information
SYNOPSIS	<pre>pkginfo [-q -x -l] [-p -i] [-r] [-a <i>arch</i>] [-v <i>version</i>] [-c <i>category...</i>] [<i>pkginst...</i>] pkginfo [-d <i>device</i>] [-R <i>root_path</i>] [-q -x -l] [-a <i>arch</i>] [-v <i>version</i>] [-c <i>category...</i>] [<i>pkginst...</i>]</pre>
DESCRIPTION	<p>pkginfo displays information about software packages that are installed on the system (with the first synopsis) or that reside on a particular device or directory (with the second synopsis).</p> <p>Without options, pkginfo lists the primary category, package instance, and the names of all completely installed and partially installed packages. It displays one line for each package selected.</p>
OPTIONS	<p>The <code>-p</code> and <code>-i</code> options are meaningless if used in conjunction with the <code>-d</code> option.</p> <p>The options <code>-q</code>, <code>-x</code>, and <code>-l</code> are mutually exclusive.</p> <p><code>-a <i>arch</i></code> Specify the architecture of the package as <i>arch</i>.</p> <p><code>-c <i>category</i></code> Display packages that match <i>category</i>. Categories are defined with the <code>CATEGORY</code> parameter in the <code>pkginfo(4)</code> file. If more than one category is supplied, the package needs to match only one category in the list. The match is not case specific.</p> <p><code>-d <i>device</i></code> Defines a device, <i>device</i>, on which the software resides. <i>device</i> can be an absolute directory pathname or the identifiers for tape, floppy disk, removable disk, and so forth. The special token <code>spool</code> may be used to indicate the default installation spool directory (<code>/var/spool/pkg</code>).</p> <p><code>-i</code> Display information for fully installed packages only.</p> <p><code>-l</code> Specify long format, which includes all available information about the designated package(s).</p> <p><code>-p</code> Display information for partially installed packages only.</p> <p><code>-q</code> Do not list any information. Used from a program to check whether or not a package has been installed.</p> <p><code>-r</code> List the installation base for relocatable packages.</p> <p><code>-R <i>root_path</i></code> Defines the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>.</p> <p><code>-v <i>version</i></code> Specify the version of the package as <i>version</i>. The version is defined with the <code>VERSION</code> parameter in the <code>pkginfo(4)</code> file. All compatible versions can be requested by preceding the version name with a tilde (<code>~</code>). Multiple white spaces are replaced with a single white space during version comparison.</p>

pkginfo(1)

- OPERANDS**
 - x Designate an extracted listing of package information. The listing contains the package abbreviation, package name, package architecture (if available) and package version (if available).
 - pkginst* A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, *inst . 1* or *inst . 2*). All instances of a package can be requested by *inst . **. The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).
- EXIT STATUS**
 - 0 Successful completion.
 - >0 An error occurred.
- FILES** /var/spool/pkg default installation spool directory
- ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Application Packaging Developer's Guide

NAME	pkgmk – produce an installable package
SYNOPSIS	pkgmk [-o] [-a <i>arch</i>] [-b <i>base_src_dir</i>] [-d <i>device</i>] [-f <i>prototype</i>] [-l <i>limit</i>] [-p <i>pstamp</i>] [-r <i>root_path</i>] [-v <i>version</i>] [<i>variable=value...</i>] [<i>pkginst</i>]
DESCRIPTION	<p>The pkgmk utility produces an installable package to be used as input to the pkgadd(1M) command. The package contents will be in directory structure format.</p> <p>The command uses the package <i>prototype(4)</i> file as input and creates a <i>pkgmap(4)</i> file. The contents for each entry in the <i>prototype</i> file is copied to the appropriate output location. Information concerning the contents (checksum, file size, modification date) is computed and stored in the <i>pkgmap</i> file, along with attribute information specified in the <i>prototype</i> file.</p> <p>pkgmk searches for the files listed in the <i>prototype(4)</i> file as described in the following conditions. <i>Note:</i> If a <i>prototype</i> file contains the explicit location of the file to include in the package, then the following search explanations do not apply.</p> <ol style="list-style-type: none"> 1. If neither <i>-b</i> nor <i>-r</i> options are specified, the file name component of each file path listed in the <i>prototype(4)</i> file is expected to be found in the same directory as the <i>prototype(4)</i> file 2. If <i>-b</i> is specified as a relative path (without a leading <i>"/</i>"), then <i>base_src_dir</i> is prepended to the relative file paths from the <i>prototype(4)</i> file. The resulting path is searched for in the <i>root_path</i> directories. If a <i>root_path</i> is not specified, it defaults to <i>"/</i>". 3. If <i>-b</i> is specified as an absolute path (with a leading <i>"/</i>"), then <i>base_src_dir</i> is prepended to the relative paths from the <i>prototype(4)</i> file and the result is the location of the file. <i>root_path</i> is <i>not</i> searched. 4. If <i>-r</i> is specified, then full file paths are used from the <i>prototype(4)</i> file. Relative paths have <i>base_src_dir</i> prepended. If <i>base_src_dir</i> is not specified, it defaults to <i>""</i>. The resulting path is searched for in each directory of the <i>root_path</i>. <p>If you created your <i>prototype</i> file using <i>"pkgproto a/relative/path"</i> or <i>"pkgproto a/relative/path=install/path"</i>, then you should use the <i>-r root_path</i> option to specify the location of <i>a/relative/path</i> so that pkgmk can correctly locate your source files.</p>
OPTIONS	<p>The following options are supported:</p> <p><i>-a arch</i> Overrides the architecture information provided in the <i>pkginfo(4)</i> file with <i>arch</i>.</p> <p><i>-b base_src_dir</i> Prepends the indicated <i>base_src_dir</i> to locate relocatable objects on the source machine. Use this option to search for all objects in the <i>prototype</i> file. pkgmk expects to find the objects in <i>/base_src_dir</i> or to locate the objects by use of the <i>-b</i> and <i>-r</i> options, respectively.</p> <p><i>-d device</i> Creates the package on <i>device</i>. <i>device</i> can be an absolute directory pathname or the identifiers for a floppy disk or removable disk</p>

pkgmk(1)

	(for example, /dev/diskette). The default device is the installation spool directory (/var/spool/pkg).
-f <i>prototype</i>	Uses the file <i>prototype</i> as input to the command. The default <i>prototype</i> filename is [Pp]rototype.
-l <i>limit</i>	Specifies the maximum size in 512 byte blocks of the output device as <i>limit</i> . By default, if the output file is a directory or a mountable device, pkgmk will employ the df(1M) command to dynamically calculate the amount of available space on the output device. This option is useful in conjunction with pkgtrans(1) to create a package with a datastream format.
-o	Overwrites the same instance; package instance will be overwritten if it already exists.
-p <i>pstamp</i>	Overrides the production stamp definition in the pkginfo(4) file with <i>pstamp</i> .
-r <i>root_path</i>	Uses the indicated <i>root_path</i> with the source pathname appended to locate objects on the source machine, using a comma (,) as the separator for the path elements. If this option is specified, look for the full destination path in each of the directories specified. If neither -b nor -r is specified, look for the leaf filename in the current directory.
-v <i>version</i>	Overrides the version information provided in the pkginfo(4) file with <i>version</i> .
<i>variable=value</i>	Places the indicated variable in the packaging environment. (See prototype(4) for definitions of variable specifications.)
OPERANDS	The following operand is supported:
<i>pkginst</i>	A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, inst.1 or inst.2). All instances of a package can be requested by inst.*. The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).
EXIT STATUS	The following exit values are returned:
0	Successful completion.
>0	An error occurred.
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO pkgparam(1), pkgproto(1), pkgtrans(1), uname(1), df(1M), pkgadd(1M), pkginfo(4), pkgmap(4), prototype(4), attributes(5)

Application Packaging Developer's Guide

NOTES Architecture information is provided on the command line with the `-a` option or in the `prototype(4)` file. If no architecture information is supplied, `pkgmk` uses the output of `uname -m` (see `uname(1)`).

Version information is provided on the command line with the `-v` option or in the `pkginfo(4)` file. If no version information is supplied, a default based on the current date will be provided.

Command line definitions for both architecture and version override the `prototype(4)` definitions.

pkgparam(1)

NAME	pkgparam – display package parameter values
SYNOPSIS	pkgparam [-v] [-d <i>device</i>] [-R <i>root_path</i>] <i>pkginst</i> [<i>param...</i>] pkgparam -f <i>filename</i> [-v] [<i>param...</i>]
DESCRIPTION	<p>pkgparam displays the value associated with the parameter or parameters requested on the command line. The values are located in either the <code>pkginfo(4)</code> file for <i>pkginst</i> or from the specific file named with the <code>-f</code> option.</p> <p>One parameter value is shown per line. Only the value of a parameter is given unless the <code>-v</code> option is used. With this option, the output of the command is in this format:</p> <pre>parameter1='value1' parameter2='value2' parameter3='value3'</pre> <p>If no parameters are specified on the command line, values for all parameters associated with the package are shown.</p>
OPTIONS	<p>Options and arguments for this command are:</p> <p><code>-d <i>device</i></code> Specify the <i>device</i> on which a <i>pkginst</i> is stored. It can be a directory pathname or the identifiers for tape, floppy disk, or removable disk (for example, <code>/var/tmp</code>, <code>/dev/diskette</code>, and <code>/dev/dsk/c1d0s0</code>). The special token <code>spool</code> may be used to represent the default installation spool directory (<code>/var/spool/pkg</code>).</p> <p><code>-f <i>filename</i></code> Read <i>filename</i> for parameter values.</p> <p><code>-R <i>root_path</i></code> Defines the full path name of a subdirectory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>.</p> <p><code>-v</code> Verbose mode. Display name of parameter and its value.</p>
OPERANDS	<p><i>pkginst</i> Defines a specific package instance for which parameter values should be displayed.</p> <p><i>param</i> Defines a specific parameter whose value should be displayed.</p>
ERRORS	If parameter information is not available for the indicated package, the command exits with a non-zero status.
EXIT STATUS	0 Successful completion. >0 An error occurred.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO pkgmk(1), pkgproto(1), pkgtrans(1), pkginfo(4), attributes(5)

Application Packaging Developer's Guide

NOTES With the `-f` option, you can specify the file from which parameter values should be extracted. This file should be in the same format as a `pkginfo(4)` file. For example, such a file might be created during package development and used while testing software during this stage.

pkgproto(1)

NAME	pkgproto – generate prototype file entries for input to pkgmk command
SYNOPSIS	pkgproto [-i] [-c <i>class</i>] [<i>path1</i>] pkgproto [-i] [-c <i>class</i>] [<i>path1=path2...</i>]
DESCRIPTION	<p>pkgproto scans the indicated paths and generates prototype(4) file entries that may be used as input to the pkgmk(1) command.</p> <p>If no paths are specified on the command line, standard input is assumed to be a list of paths. If the pathname listed on the command line is a directory, the contents of the directory is searched. However, if input is read from <code>stdin</code>, a directory specified as a pathname will not be searched.</p>
OPTIONS	<p>-i Ignores symbolic links and records the paths as <code>f type=f</code> (a file) versus <code>f type=s</code> (symbolic link).</p> <p>-c <i>class</i> Maps the class of all paths to <i>class</i>.</p>
OPERANDS	<p><i>path1</i> Pathname where objects are located.</p> <p><i>path2</i> Pathname which should be substituted on output for <i>path1</i>.</p>
EXAMPLES	<p>EXAMPLE 1 Examples of the use of pkgproto.1.</p> <p>The following two examples show uses of pkgproto and a partial listing of the output produced.</p> <p>Example 1:</p> <pre>example% pkgproto /bin=bin /usr/bin=usrbin /etc=etc f none bin/sed=/bin/sed 0775 bin bin f none bin/sh=/bin/sh 0755 bin daemon f none bin/sort=/bin/sort 0755 bin bin f none usrbin/sdb=/usr/bin/sdb 0775 bin bin f none usrbin/shl=/usr/bin/shl 4755 bin bin d none etc/master.d 0755 root daemon f none etc/master.d/kernel=/etc/master.d/kernel 0644 root daemon f none etc/rc=/etc/rc 0744 root daemon</pre> <p>Example 2:</p> <pre>example% find / -type d -print pkgproto d none / 755 root root d none /bin 755 bin bin d none /usr 755 root root d none /usr/bin 775 bin bin d none /etc 755 root root d none /tmp 777 root root</pre>
EXIT STATUS	<p>0 Successful completion.</p> <p>>0 An error occurred.</p>
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO pkgmk(1), pkgparam(1), pkgtrans(1), prototype(4), attributes(5)

Application Packaging Developer's Guide

NOTES By default, `pkgproto` creates symbolic link entries for any symbolic link encountered (`ftype=s`). When you use the `-i` option, `pkgproto` creates a file entry for symbolic links (`ftype=f`). The `prototype(4)` file would have to be edited to assign such file types as `v` (volatile), `e` (editable), or `x` (exclusive directory). `pkgproto` detects linked files. If multiple files are linked together, the first path encountered is considered the source of the link.

By default, `pkgproto` prints `prototype` entries on the standard output. However, the output should be saved in a file (named `Prototype` or `prototype`, for convenience) to be used as input to the `pkgmk(1)` command.

pkgtrans(1)

NAME	pkgtrans – translate package format
SYNOPSIS	pkgtrans [-inos] <i>device1 device2</i> [<i>pkginst...</i>]
DESCRIPTION	<p>pkgtrans translates an installable package from one format to another. It translates:</p> <ul style="list-style-type: none">■ a file system format to a datastream■ a datastream to a file system format■ one file system format to another file system format
OPTIONS	<p>The options and arguments for this command are:</p> <ul style="list-style-type: none">-i Copy only the <i>pkginfo(4)</i> and <i>pkgmap(4)</i> files.-n Create a new instance of the package on the destination device if any instance of this package already exists, up to the number specified by the <i>MAXINST</i> variable in the <i>pkginfo(4)</i> file.-o Overwrite the same instance on the destination device; package instance will be overwritten if it already exists.-s Indicates that the package should be written to <i>device2</i> as a datastream rather than as a file system. The default behavior is to write a file system format on devices that support both formats.
OPERANDS	<p><i>device1</i> Indicates the source device. The package or packages on this device will be translated and placed on <i>device2</i>.</p> <p><i>device2</i> Indicates the destination device. Translated packages will be placed on this device.</p> <p><i>pkginst</i> Specifies which package instance or instances on <i>device1</i> should be translated. The token <i>all</i> may be used to indicate all packages. <i>pkginst.*</i> can be used to indicate all instances of a package. If no packages are defined, a prompt shows all packages on the device and asks which to translate.</p> <p>The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).</p>
EXAMPLES	<p>EXAMPLE 1 Examples of the <i>pkgtrans</i> command.</p> <p>The following example translates all packages on the floppy drive <i>/dev/diskette</i> and places the translations on <i>/tmp</i>:</p> <pre>example% pkgtrans /dev/diskette /tmp all</pre> <p>The next example translates packages <i>pkg1</i> and <i>pkg2</i> on <i>/tmp</i> and places their translations (that is, a datastream) on the <i>9track1</i> output device:</p> <pre>example% pkgtrans /tmp 9track1 pkg1 pkg2</pre>

EXAMPLE 1 Examples of the `pkgtrans` command. (Continued)

The next example translates `pkg1` and `pkg2` on `/tmp` and places them on the diskette in a datastream format:

```
example% pkgtrans -s /tmp /dev/diskette pkg1 pkg2
```

ENVIRONMENT VARIABLES

The `MAXINST` variable is set in the `pkginfo(4)` file and declares the maximum number of package instances.

EXIT STATUS

0 Successful completion.
>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`pkginfo(1)`, `pkgmk(1)`, `pkgparam(1)`, `pkgproto(1)`, `installf(1M)`, `pkgadd(1M)`, `pkgask(1M)`, `pkgrm(1M)`, `removef(1M)`, `pkginfo(4)`, `pkgmap(4)`, `attributes(5)`

Application Packaging Developer's Guide

NOTES

Device specifications can be either the special node name (for example, `/dev/diskette`) or a device alias (for example, `diskette1`). The device `spool` indicates the default spool directory. Source and destination devices cannot be the same.

By default, `pkgtrans` will not translate any instance of a package if any instance of that package already exists on the destination device. Using the `-n` option creates a new instance if an instance of this package already exists. Using the `-o` option overwrites an instance of this package if it already exists. Neither of these options are useful if the destination device is a datastream.

plimit(1)

NAME	plimit – get or set the resource limits of running processes
SYNOPSIS	plimit [-km] <i>pid...</i> plimit {-cdfnstv} <i>soft,hard...</i> <i>pid...</i>
DESCRIPTION	<p>If one or more of the <i>cdfnstv</i> options is specified, plimit sets the soft (current) limit and/or the hard (maximum) limit of the indicated resource(s) in the processes identified by the process-ID list, <i>pid</i>. Otherwise plimit reports the resource limits of the processes identified by the process-ID list, <i>pid</i>.</p> <p>Only the owner of a process or the super-user is permitted either to get or to set the resource limits of a process. Only the super-user can increase the hard limit.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-k On output, show file sizes in kilobytes (1024 bytes) rather than in 512-byte blocks.-m On output, show file and memory sizes in megabytes (1024*1024 bytes). <p>The remainder of the options are used to change specified resource limits. They each accept an argument of the form:</p> <p><i>soft,hard</i></p> <p>where <i>soft</i> specifies the soft (current) limit and <i>hard</i> specifies the hard (maximum) limit. If the hard limit is not specified, the comma may be omitted. If the soft limit is an empty string, only the hard limit is set. Each limit is either the literal string <i>unlimited</i>, or a number, with an optional scaling factor, as follows:</p> <ul style="list-style-type: none"><i>nk</i> <i>n</i> kilobytes<i>nm</i> <i>n</i> megabytes (minutes for CPU time)<i>nh</i> <i>n</i> hours (for CPU time only)<i>mm:ss</i> minutes and seconds (for CPU time only) <p>The soft limit cannot exceed the hard limit.</p> <ul style="list-style-type: none">-c <i>soft,hard</i> Set core file size limits (default unit is 512-byte blocks).-d <i>soft,hard</i> Set data segment (heap) size limits (default unit is kilobytes).-f <i>soft,hard</i> Set file size limits (default unit is 512-byte blocks).-n <i>soft,hard</i> Set file descriptor limits (no default unit).-s <i>soft,hard</i> Set stack segment size limits (default unit is kilobytes).-t <i>soft,hard</i> Set CPU time limits (default unit is seconds).-v <i>soft,hard</i> Set virtual memory size limits (default unit is kilobytes).

OPERANDS The following operands are supported.

`pid` Process ID list.

EXIT STATUS `plimit` returns the exit value zero on success, non-zero on failure (such as no such process, permission denied, or invalid option).

FILES `/proc/pid/*` process information and control files

pmap(1)

NAME	pmap – display information about the address space of a process
SYNOPSIS	<pre>/usr/bin/pmap [-rslF] [pid core...] /usr/bin/pmap -x [-slF] [pid core...] /usr/bin/pmap -S [-lF] [pid core...]</pre>
DESCRIPTION	The pmap utility prints information about the address space of a process.
OPTIONS	The following options are supported: -a Prints anonymous and swap reservations for shared mappings. -F Force. Grabs the target process even if another process has control. -r Prints the process's reserved addresses. -s Prints HAT page size information.
USAGE	The pmap utility prints information about the address space of a process. Process Mappings <pre>/usr/bin/pmap [-rslF] [pid core] ...</pre> <p>By default, pmap displays the mappings in the virtual address order they are mapped into the process. The mapping size, flags and mapped object name are shown.</p> <p>Process anon/locked mapping details <pre>/usr/bin/pmap -x [-aslF] [pid core] ...</pre><p>The -x option displays additional information per mapping. The size of each mapping, the amount of resident physical memory, the amount of anonymous memory, and the amount of memory locked is shown with this option.</p><p>Swap Reservations <pre>/usr/bin/pmap -S [-alF] [pid core] ...</pre><p>The -S option displays swap reservation information per mapping.</p></p></p>
DISPLAY FORMATS	One line of output is printed for each mapping within the process, unless the -s option is specified, where one line is printed for a contiguous mapping of each hardware translation page size. Virtual Address The first column of output represents the starting virtual address of each mapping. Virtual addresses are displayed in ascending order. Virtual Mapping Size The virtual size of each mapping.

Resident Physical Memory

The amount of physical memory resident for each mapping, including that which is shared with other address spaces.

Anonymous Memory

The amount of anonymous memory is reported for each mapping. Anonymous memory shared with other address spaces is not included, unless the `-a` option is specified.

Anonymous memory is reported for the process heap, stack, for 'copy on write' pages with mappings mapped with `MAP_PRIVATE`.

Locked

The number of pages locked within the mapping. Typical examples are memory locked with `mlock()` and System V shared memory created with `SHM_SHARE_MMU`.

Permissions/Flags

The virtual memory permissions are shown for each mapping. Valid permissions are:

- `r`: The mapping may be read by the process.
- `w`: The mapping may be written by the process.
- `x`: Instructions that reside within the mapping may be executed by the process.

Flags showing additional information for each mapping may be displayed:

- `s`: The mapping is shared such that changes made in the observed address space are committed to the mapped file, and are visible from all other processes sharing the mapping.
- `R`: Swap space is not reserved for this mapping. Mappings created with `MAP_NORESERVE` and System V ISM shared memory mappings do not reserve swap space.

Mapping Name

A descriptive name for each mapping. The following major types of names are displayed for mappings:

- *A mapped file*: For mappings between a process and a file, the `pmap` command attempts to resolve the file name for each mapping. If the file name cannot be resolved, `pmap` displays the major and minor number of the device containing the file, and the file system inode number of the file.
- *Anonymous memory*: Memory not relating to any named object or file within the file system is reported as `[anon]`.

The `pmap` command displays common names for certain known anonymous memory mappings, such as:

`[heap]` The process heap.

pmap(1)

[stack] The process stack.

If the common name for the mapping is unknown, pmap displays [anon] as the mapping name.

- *System V Shared Memory:* Mappings created using System V shared memory system calls are reported with the names shown below:

shmid=n: The mapping is a System V shared memory mapping. The shared memory identifier that the mapping was created with is reported.

ism shmid=n: The mapping is an "Intimate Shared Memory" variant of System V shared memory. ISM mappings are created with the SHM_SHARE_MMU flag set, in accordance with shmat(2) (see shmop(2)).

dism shmid=n: The mapping is a pageable variant of ISM. Pageable ISM is created with the SHM_PAGEABLE flag set in accordance with shmat(2) (see shmop(2)).

- *Other:* Mappings of other objects, including devices such as frame buffers. No mapping name is shown for other mapped objects.

EXAMPLES

EXAMPLE 1 Displaying process mappings

By default, pmap prints one line for each mapping within the address space of the target process. The following example displays the address space of a typical bourne shell:

```
example$ pmap 102905
102905:  sh
00010000  192K r-x-- /usr/bin/ksh
00040000   8K rwx-- /usr/bin/ksh
00042000  40K rwx-- [ heap ]
FF180000 664K r-x-- /usr/lib/libc.so.1
FF236000  24K rwx-- /usr/lib/libc.so.1
FF23C000   8K rwx-- /usr/lib/libc.so.1
FF250000   8K rwx-- [ anon ]
FF260000  16K r-x-- /usr/lib/en_US.ISO8859-1.so.2
FF272000  16K rwx-- /usr/lib/en_US.ISO8859-1.so.2
FF280000 560K r-x-- /usr/lib/libnsl.so.1
FF31C000  32K rwx-- /usr/lib/libnsl.so.1
FF324000  32K rwx-- /usr/lib/libnsl.so.1
FF340000  16K r-x-- /usr/lib/libc_psr.so.1
FF350000  16K r-x-- /usr/lib/libmp.so.2
FF364000   8K rwx-- /usr/lib/libmp.so.2
FF380000  40K r-x-- /usr/lib/libsocket.so.1
FF39A000   8K rwx-- /usr/lib/libsocket.so.1
FF3A0000   8K r-x-- /usr/lib/libdl.so.1
FF3B0000   8K rwx-- [ anon ]
FF3C0000 152K r-x-- /usr/lib/ld.so.1
FF3F6000   8K rwx-- /usr/lib/ld.so.1
FFBFC000  16K rw--- [ stack ]
total    1880K
```

EXAMPLE 2 Displaying memory allocation and mapping types

The `-x` option can be used to provide information about the memory allocation and mapping types per mapping. The amount of resident, non-shared anonymous, and locked memory is shown for each mapping:

```
example$ pmap -x 102908
102908:  sh
Address  Kbytes Resident  Anon  Locked Mode  Mapped File
00010000  88      88      -    -    r-x--  sh
00036000   8       8       8    -    rwx--  sh
00038000  16      16      16    -    rwx--  [ heap ]
FF260000  16      16      -    -    r-x--  en_US.ISO8859-1.so.2
FF272000  16      16      -    -    rwx--  en_US.ISO8859-1.so.2
FF280000  664     624     -    -    r-x--  libc.so.1
FF336000  32      32      8    -    rwx--  libc.so.1
FF360000  16      16      -    -    r-x--  libc_psr.so.1
FF380000  24      24      -    -    r-x--  libgen.so.1
FF396000   8       8       -    -    rwx--  libgen.so.1
FF3A0000   8       8       -    -    r-x--  libdl.so.1
FF3B0000   8       8       8    -    rwx--  [ anon ]
FF3C0000  152     152     -    -    r-x--  ld.so.1
FF3F6000   8       8       8    -    rwx--  ld.so.1
FFBFE000   8       8       8    -    rw---  [ stack ]
-----  -----  -----  -----  -----
total Kb   1072   1032    56    -
```

The amount of incremental memory used by each additional instance of a process can be estimated by using the resident and anonymous memory counts of each mapping.

In the above example, the bourne shell has a resident memory size of 1032Kbytes. However, a large amount of the physical memory used by the shell is shared with other instances of shell. Another identical instance of the shell will share physical memory with the other shell where possible, and allocate anonymous memory for any non-shared portion. In the above example, each additional bourne shell uses approximately 56Kbytes of additional physical memory.

A more complex example shows the output format for a process containing different mapping types. In this example, the mappings are as follows:

```
0001000: Executable text, mapped from 'maps' program
0002000: Executable data, mapped from 'maps' program
0002200: Program heap

0300000: A mapped file, mapped MAP_SHARED
0400000: A mapped file, mapped MAP_PRIVATE

0500000: A mapped file, mapped MAP_PRIVATE | MAP_NORESERVE
0600000: Anonymous memory, created by mapping /dev/zero
0700000: Anonymous memory, created by mapping /dev/zero
```

pmap(1)

EXAMPLE 2 Displaying memory allocation and mapping types (Continued)

```
with MAP_NORESERVE

0800000: A DISM shared memory mapping, created with SHM_PAGEABLE
with 8MB locked via mlock(2)

0900000: A DISM shared memory mapping, created with SHM_PAGEABLE,
with 4MB of its pages touched.

0A00000: A DISM shared memory mapping, created with SHM_PAGEABLE,
with none of its pages touched.

0B00000: An ISM shared memory mapping, created with SHM_SHARE_MMU

example$ pmap -xs 15492

EXAMPLE 3 Displaying Page Size Information

The `-s` option can be used to display the hardware translation page sizes for each portion of the address space. (See `memcntl(2)` for further information on Solaris multiple page size support).

In the example below, we can see that the majority of the mappings are using an 8K-Byte page size, while the heap is using a 4M-Byte page size.

Notice that non-contiguous regions of resident pages of the same page size are reported as separate mappings. In the example below, the `libc.so` library is reported as separate mappings, since only some of the `libc.so` text is resident:

EXAMPLE 4 Displaying swap reservations

The `-S` option can be used to describe the swap reservations for a process. The amount of swap space reserved is displayed for each mapping within the process. Swap reservations are reported as zero for shared mappings, since they are accounted for only once system wide.

```

example$ pmap -S 15492
15492: ./maps
Address  Kbytes  Swap  Mode  Mapped File
00010000      8      -   r-x--  maps

```

The swap reservation information can be used to estimate the amount of virtual swap used by each additional process. Each process consumes virtual swap from a global virtual swap pool. Global swap reservations are reported by the 'avail' field of the swap(1M) command.

EXIT STATUS

The following exit values are returned:

```

0                Successful operation.
non-zero        An error has occurred.

```

FILES

```

/proc/*          process files
/usr/proc/lib/*  proc tools supporting files

```

NAME	postdaisy – PostScript translator for Diablo 630 daisy-wheel files
SYNOPSIS	postdaisy [-c <i>num</i>] [-f <i>num</i>] [-h <i>num</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-r <i>num</i>] [-s <i>num</i>] [-v <i>num</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>] /usr/lib/lp/postscript/postdaisy
DESCRIPTION	The <code>postdaisy</code> filter translates Diablo 630 daisy-wheel <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.
OPTIONS	<ul style="list-style-type: none"> -c <i>num</i> Print <i>num</i> copies of each page. By default only one copy is printed. -f <i>name</i> Print <i>files</i> using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant-width fonts. The default font is Courier. -h <i>num</i> Set the initial horizontal motion index to <i>num</i>. Determines the character advance and the default point size, unless the <code>-s</code> option is used. The default is 12. -m <i>num</i> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0. -n <i>num</i> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1. -o <i>list</i> Print pages whose numbers are given in the comma-separated <i>list</i>. The list contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper. -p <i>mode</i> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait. -r <i>num</i> Selects carriage return and line feed behavior. If <i>num</i> is 1, a line feed generates a carriage return. If <i>num</i> is 2, a carriage return generates a line feed. Setting <i>num</i> to 3 enables both modes. -s <i>num</i> Use point size <i>num</i> instead of the default value set by the initial horizontal motion index. -v <i>num</i> Set the initial vertical motion index to <i>num</i>. The default is 8. -x <i>num</i> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the

postdaisy(1)

page, with positive *x* to the right and positive *y* down the page. Positive *num* moves everything right. The default offset is 0.25 inches.

-y num Translate the origin *num* inches along the positive *y* axis. Positive *num* moves text up the page. The default offset is -0.25 inches.

EXIT STATUS The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

NAME	postdmd – PostScript translator for DMD bitmap files
SYNOPSIS	postdmd [-b <i>num</i>] [-c <i>num</i>] [-f] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>] /usr/lib/lp/postscript/postdmd
DESCRIPTION	postdmd translates DMD bitmap <i>files</i> , as produced by <i>dmdps</i> , or <i>files</i> written in the Ninth Edition <i>bitfile</i> (9.5) format into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if – is one of the input <i>files</i> , the standard input is read.
OPTIONS	<p>-b <i>num</i> Pack the bitmap in the output file using <i>num</i> byte patterns. A value of 0 turns off all packing of the output file. By default, <i>num</i> is 6.</p> <p>-c <i>num</i> Print <i>num</i> copies of each page. By default only one copy is printed.</p> <p>-f Flip the sense of the bits in <i>files</i> before printing the bitmaps.</p> <p>-m <i>num</i> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which by default is located at the center of each page. The default magnification is 1.0.</p> <p>-n <i>num</i> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default <i>num</i> is set to 1.</p> <p>-o <i>list</i> Print pages whose numbers are given in the comma-separated <i>list</i>. The list contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p>-p <i>mode</i> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.</p> <p>-x <i>num</i> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0 inches.</p> <p>-y <i>num</i> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.</p>
	<p>Only one bitmap is printed on each logical page, and each of the input <i>files</i> must contain complete descriptions of at least one bitmap. Decreasing the pattern size using the -b option may help throughput on printers with fast processors (such as PS-810s), while increasing the pattern size will often be the right move on older models (such as PS-800s).</p>

postdmd(1)

EXIT STATUS The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

NAME	postio – serial interface for PostScript printers
SYNOPSIS	<pre>postio -l line [-D] [-i] [-q] [-t] [-S] [-b speed] [-B num] [-L file] [-P string] [-R num] [file...]</pre> <p><code>/usr/lib/lp/postscript/postio</code></p>
DESCRIPTION	postio sends <i>files</i> to the PostScript printer attached to <i>line</i> . If no <i>files</i> are specified the standard input is sent.
OPTIONS	<p>The first group of <i>options</i> should be sufficient for most applications:</p> <ul style="list-style-type: none"> -D Enable debug mode. Guarantees that everything read on <i>line</i> will be added to the log file (standard error by default). -q Prevents status queries while <i>files</i> are being sent to the printer. When status queries are disabled a dummy message is appended to the log file before each block is transmitted. -b <i>speed</i> Transmit data over <i>line</i> at baud rate <i>speed</i>. Recognized baud rates are 1200, 2400, 4800, 9600, and 19200. The default <i>speed</i> is 9600 baud. -B <i>num</i> Set the internal buffer size for reading and writing <i>files</i> to <i>num</i> bytes. By default <i>num</i> is 2048 bytes. -l <i>line</i> Connect to the printer attached to <i>line</i>. In most cases there is no default and postio must be able to read and write <i>line</i>. If the <i>line</i> does not begin with a / it may be treated as a Datakit destination. -L <i>file</i> Data received on <i>line</i> gets put in <i>file</i>. The default log file is standard error. Printer or status messages that don't show a change in state are not normally written to <i>file</i> but can be forced out using the -D option. -P <i>string</i> Send <i>string</i> to the printer before any of the input files. The default <i>string</i> is simple PostScript code that disables timeouts. -R <i>num</i> Run postio as a single process if <i>num</i> is 1 or as separate read and write processes if <i>num</i> is 2. By default postio runs as a single process. <p>The next two <i>options</i> are provided for users who expect to run postio on their own. Neither is suitable for use in spooler interface programs:</p> <ul style="list-style-type: none"> -i Run the program in interactive mode. Any <i>files</i> are sent first and followed by the standard input. Forces separate read and write processes and overrides many other options. To exit interactive mode use your interrupt or quit character. To get a friendly interactive connection with the printer type <code>executive</code> on a line by itself.

postio(1)

-t Data received on `line` and not recognized as printer or status information is written to the standard output. Forces separate read and write processes. Convenient if you have a PostScript program that will be returning useful data to the host.

The last option is not generally recommended and should only be used if all else fails to provide a reliable connection:

-S Slow the transmission of data to the printer. Severely limits throughput, runs as a single process, disables the `-q` option, limits the internal buffer size to 1024 bytes, can use an excessive amount of CPU time, and does nothing in interactive mode.

The best performance will usually be obtained by using a large internal buffer (the `-B` option) and by running the program as separate read and write processes (the `-R 2` option). Inability to fork the additional process causes `postio` to continue as a single read/write process. When one process is used, only data sent to the printer is flow controlled.

The *options* are not all mutually exclusive. The `-i` option always wins, selecting its own settings for whatever is needed to run interactive mode, independent of anything else found on the command line. Interactive mode runs as separate read and write processes and few of the other *options* accomplish anything in the presence of the `-i` option. The `-t` option needs a reliable two way connection to the printer and therefore tries to force separate read and write processes. The `-S` option relies on the status query mechanism, so `-q` is disabled and the program runs as a single process.

In most cases `postio` starts by making a connection to `line` and then attempts to force the printer into the IDLE state by sending an appropriate sequence of `^T` (status query), `^C` (interrupt), and `^D` (end of job) characters. When the printer goes IDLE, *files* are transmitted along with an occasional `^T` (unless the `-q` option was used). After all the *files* are sent the program waits until it's reasonably sure the job is complete. Printer generated error messages received at any time except while establishing the initial connection (or when running interactive mode) cause `postio` to exit with a non-zero status. In addition to being added to the log file, printer error messages are also echoed to standard error.

EXAMPLES

EXAMPLE 1 Examples of the `postio` command.

Run as a single process at 9600 baud and send *file1* and *file2* to the printer attached to `/dev/tty01`:

```
example% postio -l /dev/tty01 file1 file2
```

Same as above except two processes are used, the internal buffer is set to 4096 bytes, and data returned by the printer gets put in file *log*:

```
example% postio -R 2 -B 4096 -l/dev/tty01 -L log file1 file2
```

Establish an interactive connection with the printer at Datakit destination *my/prINTER*:

EXAMPLE 1 Examples of the `postio` command. (Continued)

```
example% postio -i -l my/printer
```

Send file `program` to the printer connected to `/dev/tty22`, recover any data in file `results`, and put log messages in file `log`:

```
example% postio -t -l /dev/tty22 -L log program >results
```

EXIT STATUS The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsf

SEE ALSO `download(1)`, `dpost(1)`, `postdaisy(1)`, `postdmd(1)`, `postmd(1)`, `postprint(1)`, `postreverse(1)`, `posttek(1)`, `attributes(5)`

NOTES The input *files* are handled as a single PostScript job. Sending several different jobs, each with their own internal end of job mark (^D) is not guaranteed to work properly. `postio` may quit before all the jobs have completed and could be restarted before the last one finishes.

All the capabilities described above may not be available on every machine or even across the different versions of the UNIX system that are currently supported by the program.

There may be no default `line`, so using the `-l` option is strongly recommended. If omitted, `postio` may attempt to connect to the printer using the standard output. If Datakit is involved, the `-b` option may be ineffective and attempts by `postio` to impose flow control over data in both directions may not work. The `-q` option can help if the printer is connected to RADIANT. The `-S` option is not generally recommended and should be used only if all other attempts to establish a reliable connection fail.

postmd(1)

NAME	postmd – matrix display program for PostScript printers
SYNOPSIS	postmd [-b <i>num</i>] [-c <i>num</i>] [-d <i>dimen</i>] [-g <i>list</i>] [-i <i>list</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-w <i>window</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>] /usr/lib/lp/postscript/postmd
DESCRIPTION	The <code>postmd</code> filter reads a series of floating point numbers from <i>files</i> , translates them into a PostScript gray scale image, and writes the results on the standard output. In a typical application, the numbers might be the elements of a large matrix, written in row major order, while the printed image could help locate patterns in the matrix. If no <i>files</i> are specified, or if - is one of the input <i>files</i> , the standard input is read.
OPTIONS	The following options are supported: -b <i>num</i> Packs the bitmap in the output file using <i>num</i> byte patterns. A value of 0 turns off all packing of the output file. By default, <i>num</i> is 6. -c <i>num</i> Prints <i>num</i> copies of each page. By default, only one copy is printed. -d <i>dimen</i> Sets the default matrix dimensions for all input <i>files</i> to <i>dimen</i> . The <i>dimen</i> string can be given as <i>rows</i> or <i>rowsx columns</i> . If <i>columns</i> is omitted it will be set to <i>rows</i> . By default, <code>postmd</code> assumes each matrix is square and sets the number of rows and columns to the square root of the number of elements in each input file. -g <i>list</i> <i>list</i> is a comma- or space-separated string of integers, each lying between 0 and 255 inclusive, that assigns PostScript gray scales to the regions of the real line selected by the -i option. 255 corresponds to white, and 0, to black. The <code>postmd</code> filter assigns a default gray scale that omits white (that is, 255) and gets darker as the regions move from left to right along the real line. -i <i>list</i> <i>list</i> is a comma-, space-, or slash(/)-separated string of <i>N</i> floating point numbers that partition the real line into 2 <i>N</i> +1 regions. The <i>list</i> must be given in increasing numerical order. The partitions are used to map floating point numbers read from the input <i>files</i> into gray scale integers that are either assigned automatically by <code>postmd</code> or arbitrarily selected using the -g option. The default interval <i>list</i> is -1, 0, 1, which partitions the real line into seven regions. -m <i>num</i> Magnifies each logical page by the factor <i>num</i> . Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0. -n <i>num</i> Prints <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.

- o *list* Prints pages whose numbers are given in the comma separated *list*. The list contains single numbers *N* and ranges *N1* – *N2*. A missing *N1* means the lowest numbered page, a missing *N2* means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then *only* page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.
- p *mode* Prints *files* in either portrait or landscape *mode*. Only the first character of *mode* is significant. The default *mode* is portrait.
- w *window* *window* is a comma- or space-separated list of four positive integers that select the upper left and lower right corners of a submatrix from each of the input *files*. Row and column indices start at 1 in the upper left corner and the numbers in the input *files* are assumed to be written in row major order. By default, the entire matrix is displayed.
- x *num* Translates the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive *num* moves everything right. The default offset is 0 inches.
- y *num* Translates the origin *num* inches along the positive y axis. Positive *num* moves everything up the page. The default offset is 0.

Only one matrix is displayed on each logical page, and each of the input *files* must contain complete descriptions of exactly one matrix. Matrix elements are floating point numbers arranged in row major order in each input file. White space, including newlines, is not used to determine matrix dimensions. By default, `postmd` assumes each matrix is square and sets the number of rows and columns to the square root of the number of elements in the input file. Supplying default dimensions on the command line with the `-d` option overrides this default behavior, and in that case the dimensions apply to all input *files*.

An optional header can be supplied with each input file and is used to set the matrix dimensions, the partition of the real line, the gray scale map, and a window into the matrix. The header consists of keyword/value pairs, each on a separate line. It begins on the first line of each input file and ends with the first unrecognized string, which should be the first matrix element. Values set in the header take precedence, but apply only to the current input file. Recognized header keywords are `dimension`, `interval`, `grayscale`, and `window`. The syntax of the value string that follows each keyword parallels what is accepted by the `-d`, `-i`, `-g`, and `-w` options.

postmd(1)

EXAMPLES

EXAMPLE 1 Generating an interval list

For example, suppose *file* initially contains the 1000 numbers in a 20x50 matrix. Then you can produce exactly the same output by completing three steps.

1. First, issue the following command line:

```
example% postmd -d20x50 -i"-100 100" -g0,128,254,128,0 file
```

2. Second, prepend the following header to *file*:

```
example% postmd -d20x50 -i"-100 100" -g0,128,254,128,0 file
```

3. Third, issue the following command line:

```
example% postmd file
```

The interval list partitions the real line into five regions and the gray scale list maps numbers less than -100 or greater than 100 into 0 (that is, black), numbers equal to -100 or 100 into 128 (that is, 50 percent black), and numbers between -100 and 100 into 254 (that is, almost white).

FILES

/usr/lib/lp/postscript/forms.ps

/usr/lib/lp/postscript/ps.requests

EXIT STATUS

The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsf

SEE ALSO

`dpost(1)`, `postdaisy(1)`, `postdmd(1)`, `postio(1)`, `postprint(1)`, `postreverse(1)`, `posttek(1)`, `attributes(5)`

NOTES

The largest matrix that can be adequately displayed is a function of the interval and gray scale lists, the printer resolution, and the paper size. A 600 by 600 matrix is an optimistic upper bound for a two element interval list (that is, five regions) using 8.5 by 11 inch paper on a 300 dpi printer.

Using white (that is, 255) in a gray scale list is not recommended and won't show up in the legend and bar graph that `postmd` displays below each image.

NAME	postplot – PostScript translator for plot(4B) graphics files
SYNOPSIS	postplot [-c <i>num</i>] [-f <i>name</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-w <i>num</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>filename...</i>] /usr/lib/lp/postscript/postplot
DESCRIPTION	The <code>postplot</code> filter translates <code>plot(1B)</code> graphics <i>filenames</i> into PostScript and writes the results on the standard output. If no <i>filenames</i> are specified, or if <code>-</code> is one of the input <i>filenames</i> , the standard input is read.
OPTIONS	The following options are supported: -c <i>num</i> Print <i>num</i> copies of each page. By default, only one copy is printed. -f <i>name</i> Print text using font <i>name</i> . Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier. -m <i>num</i> Magnify each logical page by the factor <i>num</i> . Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0. -n <i>num</i> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1. -o <i>list</i> Print pages whose numbers are given in the comma-separated <i>list</i> . The list contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i> . A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. -p <i>mode</i> Print <i>filenames</i> in either portrait or landscape <i>mode</i> . Only the first character of <i>mode</i> is significant. The default <i>mode</i> is landscape. -w <i>num</i> Set the line width used for graphics to <i>num</i> points, where a point is approximately 1/72 of an inch. By default, <i>num</i> is set to 0 points, which forces lines to be one pixel wide. -x <i>num</i> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0.0 inches. -y <i>num</i> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.0.
OPERANDS	The following operand is supported: <i>filename</i> The graphics filename to be translated
EXIT STATUS	The following exit value is returned: 0 <i>filename(s)</i> were successfully processed.

postplot(1)

FILES /usr/lib/lp/postscript/forms.ps
/usr/lib/lp/postscript/postplot.ps

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWlps

SEE ALSO `download(1)`, `dpost(1)`, `plot(1B)`, `postdaisy(1)`, `postdmd(1)`, `postio(1)`, `postmd(1)`, `postprint(1)`, `postreverse(1)`, `plot(4B)`, `attributes(5)`

NOTES The default line width is too small for write-white print engines, such as the one used by the PS-2400.

NAME	postprint – PostScript translator for text files
SYNOPSIS	postprint [-c <i>num</i>] [-f <i>name</i>] [-l <i>num</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-r <i>num</i>] [-s <i>num</i>] [-t <i>num</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>] /usr/lib/lp/postscript/postprint
DESCRIPTION	The <code>postprint</code> filter translates text <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.
OPTIONS	<p><code>-c <i>num</i></code> Print <i>num</i> copies of each page. By default, only one copy is printed.</p> <p><code>-f <i>name</i></code> Print <i>files</i> using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.</p> <p><code>-l <i>num</i></code> Set the length of a page to <i>num</i> lines. By default, <i>num</i> is 66. Setting <i>num</i> to 0 is allowed, and will cause <code>postprint</code> to guess a value, based on the point size that's being used.</p> <p><code>-m <i>num</i></code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.</p> <p><code>-n <i>num</i></code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</p> <p><code>-o <i>list</i></code> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p <i>mode</i></code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.</p> <p><code>-r <i>num</i></code> Selects carriage return behavior. Carriage returns are ignored if <i>num</i> is 0, cause a return to column 1 if <i>num</i> is 1, and generate a newline if <i>num</i> is 2. The default <i>num</i> is 0.</p> <p><code>-s <i>num</i></code> Print <i>files</i> using point size <i>num</i>. When printing in landscape mode <i>num</i> is scaled by a factor that depends on the imaging area of the device. The default size for portrait mode is 10. Note that increasing point size increases virtual image size, so you either need to load larger paper, or use the <code>-l0</code> option to scale the number of lines per page.</p> <p><code>-t <i>num</i></code> Assume tabs are set every <i>num</i> columns, starting with the first column. By default, tabs are set every 8 columns.</p>

postprint(1)

- x *num* Translate the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive *num* moves everything to the right. The default offset is 0.25 inches.
- y *num* Translate the origin *num* inches along the positive y axis. Positive *num* moves text up the page. The default offset is -0.25 inches.

A new logical page is started after 66 lines have been printed on the current page, or whenever an ASCII form feed character is read. The number of lines per page can be changed using the -l option. Unprintable ASCII characters are ignored, and lines that are too long are silently truncated by the printer.

EXAMPLES **EXAMPLE 1** Examples of postprint.

To print *file1* and *file2* in landscape mode, issue the following command:

```
example% postprint -pland file1 file2
```

To print three logical pages on each physical page in portrait mode:

```
example% postprint -n3 file
```

EXIT STATUS The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

NAME	postreverse – reverse the page order in a PostScript file
SYNOPSIS	postreverse [-o <i>list</i>] [-r] [<i>file</i>] /usr/lib/lp/postscript/postreverse
DESCRIPTION	<p>The <code>postreverse</code> filter reverses the page order in files that conform to Adobe's Version 1.0 or Version 2.0 file structuring conventions, and writes the results on the standard output. Only one input <code>file</code> is allowed and if no <code>file</code> is specified, the standard input is read.</p> <p>The <code>postreverse</code> filter can handle a limited class of files that violate page independence, provided all global definitions are bracketed by <code>%%BeginGlobal</code> and <code>%%EndGlobal</code> comments. In addition, files that mark the end of each page with <code>%%EndPage: label ordinal</code> comments will also reverse properly, provided the prologue and trailer sections can be located. If <code>postreverse</code> fails to find an <code>%%EndProlog</code> or <code>%%EndSetup</code> comment, the entire <code>file</code> is copied, unmodified, to the standard output.</p> <p>Because global definitions are extracted from individual pages and put in the prologue, the output file can be minimally conforming, even if the input <code>file</code> was not.</p>
OPTIONS	<p><code>-o list</code> Select pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-r</code> Do not reverse the pages in <i>file</i>.</p>
EXAMPLES	<p>EXAMPLE 1 Examples of <code>postreverse</code>.</p> <p>o select pages 1 to 100 from <i>file</i> and reverse the pages: example% <code>postreverse -o1-100 file</code></p> <p>To print four logical pages on each physical page and reverse all the pages: example% <code>postprint -n4 file postreverse</code></p> <p>To produce a minimally conforming file from output generated by <code>dpost</code> without reversing the pages: example% <code>dpost file postreverse -r</code></p>
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p>

postreverse(1)

non-zero An error occurred.

SEE ALSO `download(1)`, `dpost(1)`, `postdaisy(1)`, `postdmd(1)`, `postio(1)`, `postmd(1)`, `postprint(1)`, `posttek(1)`, `attributes(5)`

NOTES No attempt has been made to deal with redefinitions of global variables or procedures. If standard input is used, the input file will be read three times before being reversed.

NAME	posttek – PostScript translator for Tektronix 4014 files				
SYNOPSIS	<pre>posttek [-c num] [-f name] [-m num] [-n num] [-o list] [-p mode] [-w num] [-x num] [-y num] [file...]</pre> <p>/usr/lib/lp/postscript/posttek</p>				
DESCRIPTION	The <code>posttek</code> filter translates Tektronix 4014 graphics <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.				
OPTIONS	<p><code>-c num</code> Print <i>num</i> copies of each page. By default, only one copy is printed.</p> <p><code>-f name</code> Print text using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.</p> <p><code>-m num</code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0.</p> <p><code>-n num</code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</p> <p><code>-o list</code> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p mode</code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is landscape.</p> <p><code>-w num</code> Set the line width used for graphics to <i>num</i> points, where a point is approximately 1/72 of an inch. By default, <i>num</i> is set to 0 points, which forces lines to be one pixel wide.</p> <p><code>-x num</code> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0.0 inches.</p> <p><code>-y num</code> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.0.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <table border="0"> <tr> <td style="padding-right: 20px;">0</td> <td>Successful completion.</td> </tr> <tr> <td>non-zero</td> <td>An error occurred.</td> </tr> </table>	0	Successful completion.	non-zero	An error occurred.
0	Successful completion.				
non-zero	An error occurred.

by the PS-2400.

NAME	ppgsz – set preferred stack and/or heap page size
SYNOPSIS	<code>/usr/bin/ppgsz [-F] -o option [,option] cmd -p pid...</code>
DESCRIPTION	The <code>ppgsz</code> utility sets the preferred stack and/or heap page size for the target process(es), that is, the launched <code>cmd</code> or the process(es) in the pid list. <code>ppgsz</code> stops the target process(es) while changing the page size. See <code>memcntl(2)</code> .
OPTIONS	<p>The following options are supported:</p> <p><code>-F</code> Force. Sets the preferred page size options(s) for target process(es) even if controlled by other process(es). Caution should be exercised when using the <code>-F</code> flag. See <code>proc(1)</code>.</p> <p><code>-p pid</code> Sets the preferred page size option(s) for the target process(es) in the process-id (<code>pid</code>) list following the <code>-p</code> option. The pid list can also consist of names in the <code>/proc</code> directory. Only the process owner or the super-user is permitted to set page size.</p> <p><code>cmd</code> is interpreted if <code>-p</code> is not specified. <code>ppgsz</code> launches <code>cmd</code> and applies page size option(s) to the new process.</p> <p>The heap and stack preferred page sizes are inherited. Child process(es) created (see <code>fork(2)</code>) from the launched process or the target process(es) in the pid list after <code>ppgsz</code> completes will inherit the preferred heap and stack page sizes. The preferred page sizes are set back to the default system page size on <code>exec(2)</code> (see <code>getpagesize(3C)</code>).</p> <p><code>-o option[,option]</code> The options are:</p> <p style="padding-left: 20px;"><code>heap=size</code> This option specifies the preferred page size for the heap of the target process(es). <code>heap</code> is defined to be the bss (uninitialized data) and the brk area that immediately follows the bss (see <code>brk(2)</code>). The preferred heap page size is set for the existing heap and for any additional heap memory allocated in the future. See NOTES.</p> <p style="padding-left: 20px;"><code>stack=size</code> This option specifies the preferred page size for the stack of the target process(es). The preferred stack page size is set for the existing stack and newly allocated parts of the stack as it expands.</p> <p>At least one of the above options must be specified.</p> <p><code>size</code> must be a supported page size (see <code>pagesize(1)</code>) or 0, in which case the system will select an appropriate page size (see <code>memcntl(2)</code>).</p>

ppgsz(1)

size defaults to bytes and can be specified in octal (0), decimal, or hexadecimal (0x). The numeric value can be qualified with K, M, G, or T to specify Kilobytes, Megabytes, Gigabytes, or Terabytes, respectively. 4194304, 0x400000, 4096K, 0x1000K, and 4M are different ways to specify 4 Megabytes.

EXAMPLES **EXAMPLE 1** Setting the preferred heap and stack page size

The following example sets the preferred heap page size to 4M and the preferred stack page size to 512K for all ora—owned processes running commands that begin with ora:

```
example% ppgsz -o heap=4M,stack=512K -p `pgrep -u ora '^ora`
```

EXIT STATUS If *cmd* is specified and successfully invoked (see *exec(2)*), the exit status of *ppgsz* will be the exit status of *cmd*. Otherwise, *ppgsz* will exit with one of the following values:

- 0 Successfully set preferred page size(s) for processes in the pid list.
- 125 An error occurred in *ppgsz*. Errors include: invalid argument, invalid page size(s) specified, and failure to set preferred page size(s) for one or more processes in the pid list or *cmd*.
- 126 *cmd* was found but could not be invoked.
- 127 *cmd* could not be found.

FILES /proc/* Process files.

Linker and Libraries Guide

NOTES Due to resource constraints, the setting of the preferred page size does not necessarily guarantee that the target process(es) will get the preferred page size. Use *pmap(1)* to view the *actual* heap and stack page sizes of the target process(es) (see *pmap -s* option).

ppgsz(1)

Large pages are required to be mapped at addresses that are multiples of the size of the large page. Given that the heap is typically not large page aligned, the starting portions of the heap (below the first large page aligned address) are mapped with the system memory page size. See `getpagesize(3C)`.

To provide a heap that will be mapped with a large page size, an application can be built using a link-editor (`ld(1)`) `mapfile` containing the `bss` segment declaration directive. Refer to the section “Mapfile Option” in the *Linker and Libraries Guide* for more details of this directive and the template `mapfile` provided in `/usr/lib/ld/map.bssalign`. Users are cautioned that an alignment specification may be machine-specific and may lose its benefit on different hardware platforms. A more flexible means of requesting the most optimal underlying page size may evolve in future releases.

`mpss.so.1(1)`, a preloadable shared object, can also be used to set the preferred stack and/or heap page sizes.

pr(1)

NAME	pr – print files				
SYNOPSIS	<pre>/usr/bin/pr [+ page] [-column] [-adFmrt] [-e [char] [gap]] [-h header] [-i [char] [gap]] [-l lines] [-n [char] [width]] [-o offset] [-s [char]] [-w width] [-fp] [file...] /usr/xpg4/bin/pr [+ page] [-column -c column] [-adFmrt] [-e [char] [gap]] [-h header] [-i [char] [gap]] [-l lines] [-n [char] [width]] [-o offset] [-s [char]] [-w width] [-fp] [file...]</pre>				
DESCRIPTION	<p>The <code>pr</code> utility is a printing and pagination filter. If multiple input files are specified, each is read, formatted, and written to standard output. By default, the input is separated into 66-line pages, each with:</p> <ul style="list-style-type: none">■ a 5-line header that includes the page number, date, time and the path name of the file■ a 5-line trailer consisting of blank lines <p>If standard output is associated with a terminal, diagnostic messages will be deferred until the <code>pr</code> utility has completed processing.</p> <p>When options specifying multi-column output are specified, output text columns will be of equal width; input lines that do not fit into a text column will be truncated. By default, text columns are separated with at least one blank character.</p>				
OPTIONS	<p>The following options are supported. In the following option descriptions, <i>column</i>, <i>lines</i>, <i>offset</i>, <i>page</i>, and <i>width</i> are positive decimal integers; <i>gap</i> is a non-negative decimal integer. Some of the option-arguments are optional, and some of the option-arguments cannot be specified as separate arguments from the preceding option letter. In particular, the <code>-s</code> option does not allow the option letter to be separated from its argument, and the options <code>-e</code>, <code>-i</code>, and <code>-n</code> require that both arguments, if present, not be separated from the option letter.</p> <p>The following options are supported for both <code>/usr/bin/pr</code> and <code>/usr/xpg4/bin/pr</code>:</p> <table><tr><td><code>+page</code></td><td>Begins output at page number <i>page</i> of the formatted input.</td></tr><tr><td><code>-column</code></td><td>Produces multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code>. The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column will never exceed the length of the page (see the <code>-l</code> option). When used with <code>-t</code>, use the minimum number of lines to write the output.</td></tr></table>	<code>+page</code>	Begins output at page number <i>page</i> of the formatted input.	<code>-column</code>	Produces multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code> . The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column will never exceed the length of the page (see the <code>-l</code> option). When used with <code>-t</code> , use the minimum number of lines to write the output.
<code>+page</code>	Begins output at page number <i>page</i> of the formatted input.				
<code>-column</code>	Produces multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code> . The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column will never exceed the length of the page (see the <code>-l</code> option). When used with <code>-t</code> , use the minimum number of lines to write the output.				

-a	Modifies the effect of the <code>-column</code> option so that the columns are filled across the page in a round-robin order (for example, when <code>column</code> is 2, the first input line heads column 1, the second heads column 2, the third is the second line in column 1, and so forth).
-d	Produces output that is double-spaced; append an extra NEWLINE character following every NEWLINE character found in the input.
-e [<i>char</i>] [<i>gap</i>]	Expands each input TAB character to the next greater column position specified by the formula $n * gap + 1$, where n is an integer > 0 . If <i>gap</i> is 0 or is omitted, it defaults to 8. All TAB characters in the input will be expanded into the appropriate number of SPACE characters. If any non-digit character, <i>char</i> , is specified, it will be used as the input tab character.
-f	Uses a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters. Pauses before beginning the first page if the standard output is associated with a terminal.
-h <i>header</i>	Uses the string <i>header</i> to replace the contents of the <i>file</i> operand in the page header.
-l <i>lines</i>	Overrides the 66-line default and reset the page length to <i>lines</i> . If <i>lines</i> is not greater than the sum of both the header and trailer depths (in lines), <code>pr</code> will suppress both the header and trailer, as if the <code>-t</code> option were in effect.
-m	Merges files. Standard output will be formatted so <code>pr</code> writes one line from each file specified by <i>file</i> , side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations support merging of at least nine <i>files</i> .
-n [<i>char</i>] [<i>width</i>]	Provides <i>width</i> -digit line numbering (default for <i>width</i> is 5). The number will occupy the first <i>width</i> column positions of each text column of default output or each line of <code>-m</code> output. If <i>char</i> (any non-digit character) is given, it will be appended to the line number to separate it from whatever follows (default for <i>char</i> is a TAB character).
-o <i>offset</i>	Each line of output will be preceded by <code>offset <space>s</code> . If the <code>-o</code> option is not specified, the default offset is 0. The space taken will be in addition to the output line width (see <code>-w</code> option below).

pr(1)

	-p	Pauses before beginning each page if the standard output is directed to a terminal (<code>pr</code> will write an ALERT character to standard error and wait for a carriage-return character to be read on <code>/dev/tty</code>).
	-r	Writes no diagnostic reports on failure to open files.
	-s [<i>char</i>]	Separates text columns by the single character <i>char</i> instead of by the appropriate number of SPACE characters (default for <i>char</i> is the TAB character).
	-t	Writes neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quits writing after the last line of each file without spacing to the end of the page.
	-w <i>width</i>	Sets the width of the line to <i>width</i> column positions for multiple text-column output only. If the <code>-w</code> option is not specified and the <code>-s</code> option is not specified, the default width is 72. If the <code>-w</code> option is not specified and the <code>-s</code> option is specified, the default width is 512. For single column output, input lines will not be truncated.
/usr/bin/pr	The following options are supported for <code>/usr/bin/pr</code> only:	
	-F	Folds the lines of the input file. When used in multi-column mode (with the <code>-a</code> or <code>-m</code> options), lines will be folded to fit the current column's width. Otherwise, they will be folded to fit the current line width (80 columns).
	-i [<i>char</i>] [<i>gap</i>]	In output, replaces SPACE characters with TAB characters wherever one or more adjacent SPACE characters reach column positions <i>gap</i> +1, 2* <i>gap</i> +1, 3* <i>gap</i> +1, and so forth. If <i>gap</i> is 0 or is omitted, default TAB settings at every eighth column position are assumed. If any non-digit character, <i>char</i> , is specified, it will be used as the output TAB character.
/usr/xpg4/bin/pr	The following options are supported for <code>/usr/xpg4/bin/pr</code> only:	
	-F	Uses a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters.
	-i [<i>char</i>] [<i>gap</i>]	In output, replaces multiple SPACE characters with TAB characters wherever two or more adjacent SPACE characters reach column positions <i>gap</i> +1, 2* <i>gap</i> +1, 3* <i>gap</i> +1, and so forth. If <i>gap</i> is 0 or is omitted, default

TAB settings at every eighth column position are assumed. If any non-digit character, *char*, is specified, it will be used as the output TAB character.

OPERANDS The following operand is supported:

file A path name of a file to be written. If no *file* operands are specified, or if a *file* operand is -, the standard input will be used.

EXAMPLES **EXAMPLE 1** Printing a numbered list of all files in the current directory

```
example% ls -a | pr -n -h "Files in $(pwd) ."
```

EXAMPLE 2 Printing files in columns

This example prints *file1* and *file2* as a double-spaced, three-column listing headed by *file list*:

```
example% pr -3d -h "file list" file1 file2
```

EXAMPLE 3 Writing files with expanded column tabs

The following example writes *file1* on *file2*, expanding tabs to columns 10, 19, 28, ...

```
example% pr -e9 -t <file1 >file2
```

ENVIRONMENT VARIABLES See *environ(5)* for descriptions of the following environment variables that affect the execution of *pr*: *LANG*, *LC_ALL*, *LC_CTYPE*, *LC_MESSAGES*, *LC_TIME*, *TZ*, and *NLSPATH*.

NAME	praliases – display system mail aliases					
SYNOPSIS	praliases [-c <i>configfile</i>] [-f <i>aliasfile</i>] [<i>key</i>]					
DESCRIPTION	The <i>praliases</i> utility displays system mail aliases. When no key is given, <i>praliases</i> displays the current system aliases, one per line, in no particular order. The form is <i>key:value</i> . If a key is given, only that key is looked up and the appropriate <i>key:value</i> is displayed if found.					
OPTIONS	The following options are supported:					
	-c <i>configfile</i>	Specifies a sendmail configuration file.				
	-f <i>aliasfile</i>	Reads the specified file <i>aliasfile</i> instead of the default sendmail system aliases file.				
OPERANDS	The following operands are supported:					
	<i>key</i>	A specific alias key to look up.				
EXIT STATUS	The following exit values are returned:					
	0	Successful operation.				
	>0	An error occurred.				
FILES	/etc/mail/aliases	Default sendmail system aliases file				
	/etc/mail/aliases.db	Database versions of the /etc/mail/aliases file				
	/etc/mail/aliases.dir					
	/etc/mail/aliases.pag	Database versions of the /etc/mail/aliases file

prctl(1)

NAME	prctl – get or set the resource controls of running processes, tasks, and projects
SYNOPSIS	prctl [-t [basic privileged system]] [-e -d <i>action</i>] [-rx] [-n <i>name</i> [-v <i>value</i>]] [-i <i>idtype</i>] [<i>id...</i>]
DESCRIPTION	The prctl utility allows the examination and modification of the resource controls associated with an active process, task, or project on the system. It allows access to the basic and privileged limits on the specified entity.
OPTIONS	The following options are supported: -d -e <i>action</i> Disables (-d) or enables (-e) the specified <i>action</i> on the specified resource control. The special token all is valid with the disable option to deactivate all actions on the given resource control value. The other defined actions for a resource are deny and signal=signum . The deny action indicates that the resource control encountered will attempt to deny granting the resource to the process, task, or project on a request for resources in excess of the value provided by the -v option for the new resource control. In the signal=signum action, <i>signum</i> is a signal number (or string representation of a signal). deny actions may not be activated or deactivated if global flags indicate that the deny action is unchangeable. -i <i>idtype</i> Specifies the type of the id operands. Valid <i>idtypes</i> are process , task , or project . The default id type, if the -i option is omitted, is process . -n <i>name</i> Specifies the name of the resource control to get or set. If the <i>name</i> is unspecified, all resource controls are retrieved. -r Replaces the first resource control value (matching with the -t privilege) with the new value specified through the -v option. -t [basic privileged system] Specifies which resource control type to set. Unless the "lowerable" flag is set for a resource control, only invocations by users (or setuid programs) who have privileges equivalent to those of root can modify privileged resource controls. See

rctlblk_set_value(3C) for a description of the RCTL_GLOBAL_LOWERABLE flag. If the type is not specified, `basic` is assumed. For a get operation, the values of all resource control types, including `system`, are displayed if no type is specified.

`-v value`

Specifies the value for the resource control for a set operation. If no *value* is specified, then the modification (deletion, action enabling or disabling) will be carried out on the lowest-valued resource control with the given type.

`-x`

Deletes the specified resource control value. If the delete option is not provided, the default operation of `prctl` is to modify a resource control value of matching value and privilege, or insert a new value with the given privilege. The matching criteria are discussed more fully in `setrctl(2)`.

If none of the `-d`, `-e`, `-v`, or `-x` options is specified, the invocation is considered a get operation.

OPERANDS The following operand is supported:

id The ID of the entity (`process`, `task`, or `project`) to interrogate. If the invoking user's credentials are unprivileged and the entity being interrogated possesses different credentials, the operation will fail. If no *id* is specified, an error message is returned.

EXAMPLES **EXAMPLE 1** Displaying current resource control settings for a specific process

```
example$ pgrep sort
111759
example$ prctl 111759
111759: /usr/bin/sort
process.max-address-space      [ lowerable deny no-local-action ]
    18446744073709551615 privileged deny
    18446744073709551615 system    deny
process.max-file-descriptor    [ lowerable deny ]
    256 basic                      deny
    65536 privileged               deny
    2147483647 system              deny
process.max-core-size          [ lowerable deny no-local-action ]
    18446744073709551615 privileged deny
    18446744073709551615 system    deny
process.max-stack-size         [ lowerable deny no-local-action ]
    8388608 basic                  deny
    9223372036854775807 privileged deny
    9223372036854775807 system    deny
process.max-data-size          [ lowerable deny no-local-action ]
```

prctl(1)

EXAMPLE 1 Displaying current resource control settings for a specific process (Continued)

```

18446744073709551615 privileged deny
18446744073709551615 system deny
process.max-file-size [ lowerable deny file-size ]
9223372036854775807 privileged signal=XFSZ deny
9223372036854775807 system deny
process.max-cpu-time [ lowerable no-deny cpu-time ]
18446744073709551615 privileged signal=XCPU
18446744073709551615 system deny [ infinite ]
task.max-cpu-time [ no-deny cpu-time ]

NAME	preap – force a defunct process to be reaped by its parent				
SYNOPSIS	preap [-F] <i>pid</i> ...				
DESCRIPTION	<p>A defunct (or zombie) process is one whose exit status has yet to be reaped by its parent. The exit status is reaped via the <code>wait(2)</code>, <code>waitid(2)</code>, or <code>waitpid(2)</code> system call. In the normal course of system operation, zombies may occur, but are typically short-lived. This may happen if a parent exits without having reaped the exit status of some or all of its children. In that case, those children are reparented to <code>PID 1</code>. See <code>init(1M)</code>, which periodically reaps such processes.</p> <p>An irresponsible parent process may not exit for a very long time and thus leave zombies on the system. Since the operating system destroys nearly all components of a process before it becomes defunct, such defunct processes do not normally impact system operation. However, they do consume a small amount of system memory.</p> <p><code>preap</code> forces the parent of the process specified by <i>pid</i> to <code>waitid(2)</code> for <i>pid</i>, if <i>pid</i> represents a defunct process.</p> <p><code>preap</code> will attempt to prevent the administrator from unwisely reaping a child process which might soon be reaped by the parent, if:</p> <ul style="list-style-type: none"> ■ The process is a child of <code>init(1M)</code>. ■ The parent process is stopped and might wait on the child when it is again allowed to run. ■ The process has been defunct for less than one minute. 				
OPTIONS	<p>The following option is supported:</p> <p>-F Forces the parent to reap the child, overriding safety checks.</p>

preap(1)

WARNINGS

preap should be applied sparingly and only in situations in which the administrator or developer has confirmed that defunct processes will not be reaped by the parent process. Otherwise, applying preap may damage the parent process in unpredictable ways.

NAME	prex – control tracing and manipulate probe points in a process or the kernel
SYNOPSIS	<pre>prex [-o trace_file_name] [-l libraries] [-s kbytes_size] cmd [cmd-args...] prex [-o trace_file_name] [-l libraries] [-s kbytes_size] -p pid prex -k [-s kbytes_size]</pre>
DESCRIPTION	<p>The <code>prex</code> command is the part of the Solaris tracing architecture that controls probes in a process or the kernel. See <code>tracing(3TNF)</code> for an overview of this tracing architecture, including example source code using it.</p> <p><code>prex</code> is the application used for external control of probes. It automatically preloads the <code>libtnfprobe</code> library. <code>prex</code> locates all the probes in a target executable or the kernel and provides an interface for the user to manipulate them. It allows a probe to be turned on for tracing, debugging, or both. Tracing generates a TNF (Trace Normal Form) trace file that can be converted to ASCII by <code>tnfdump(1)</code> and used for performance analysis. Debugging generates a line to standard error whenever the probe is hit at run time.</p> <p><code>prex</code> does not work on static executables. It only works on dynamic executables.</p>
Invoking prex	<p>There are three ways to invoke <code>prex</code>:</p> <ol style="list-style-type: none"> 1. Use <code>prex</code> to start the target application <code>cmd</code>. In this case, the target application need not be built with a dependency on <code>libtnfprobe</code>. See <code>TNF_PROBE(3TNF)</code>. <code>prex</code> sets the environment variable <code>LD_PRELOAD</code> to load <code>libtnfprobe</code> into the target process. See <code>ld(1)</code>. <code>prex</code> then uses the environment variable <code>PATH</code> to find the target application. 2. Attach <code>prex</code> to a running application. In this case, the running target application should have <code>libtnfprobe</code> already linked in. Alternatively, the user may manually set <code>LD_PRELOAD</code> to include <code>libtnfprobe.so.1</code> prior to invoking the target. 3. Use <code>prex</code> with the <code>-k</code> option to set <code>prex</code> to kernel mode. <code>prex</code> can then be used to control probes in the Solaris kernel. In kernel mode, additional commands are defined, and some commands that are valid in other modes are invalid. See <code>Kernel Mode</code> below.
Control File Format and Command Language	<p>In a future release of <code>prex</code>, the command language may be moved to a syntax that is supported by an existing scripting language like <code>ksh(1)</code>. In the meantime, the interface to <code>prex</code> is uncommitted.</p> <ul style="list-style-type: none"> ■ Commands should be in ASCII. ■ Each command is terminated with the NEWLINE character. ■ A command can be continued onto the next line by ending the previous line with the backslash ("<code>\</code>") character. ■ Tokens in a command must be separated by whitespace (one or more spaces or tabs). ■ The "<code>#</code>" character implies that the rest of the line is a comment.

prex(1)

Basic prex Commands

Command	Result
% prex a.out	Attaches <code>prex</code> to your program and starts <code>prex</code> .
prex> enable \$all	Enables all the probes.
prex> quit resume	Quits <code>prex</code> and resumes execution of program.

Control File Search Path

There are two different methods of communicating with `prex`:

- By specifications in a control file. During start-up, `prex` searches for a file named `.prexrc` in the directories specified below. `prex` does not stop at the first one it finds. This way a user can override any defaults that are set up. The search order is:

```
$HOME/  
./
```

- By typing commands at the `prex` prompt.

The command language for both methods is the same and is specified in `USAGE`. The commands that return output will not make sense in a control file. The output will go to standard output.

When using `prex` on a target process, the target will be in one of two states, running or stopped. This can be detected by the presence or absence of the `prex>` prompt. If the prompt is absent, it means that the target process is running. Typing Control-C will stop the target process and return the user to the prompt. There is no guarantee that Control-C will return to a `prex` prompt immediately. For example, if the target process is stopped on a job control stop (`SIGSTOP`), then Control-C in `prex` will wait until the target has been continued (`SIGCONT`). See `Signals to Target Program` below for more information on signals and the target process.

OPTIONS

The following options are supported:

- k kernel mode: `prex` is used to control probes in the Solaris kernel. In kernel mode, additional commands are defined, and some commands valid in other modes are invalid. See `Kernel Mode` below.
- l *libraries* The *libraries* mentioned are linked in to the target application using `LD_PRELOAD` (see `ld(1)`). This option cannot be used when attaching to a running process. The argument to the `-l` option should be a space-separated string enclosed in double quotes. Each token in the string is a library name. It follows the `LD_PRELOAD` rules on how libraries should be specified and where they will be found.

- `-o trace_file_name` File to be used for the trace output. *trace_file_name* is assumed to be relative to the current working directory of `prex` (that is, the directory that the user was in when `prex` was started).
- If `prex` attaches to a process that is already tracing, the new *trace_file_name* (if provided) will not be used. If no *trace_file_name* is specified, the default is `/${TMPDIR}/trace-pid` where *pid* is the process id of the target program. If `TMPDIR` is not set, `/tmp` is used.
- `-s kbytes_size` Maximum size of the output trace file in Kbytes. The default size of the trace *kbytes_size* is 4096 (2¹⁰) bytes or 4 Mbytes for normal usage, and 384 or 384 kbytes in kernel mode. The minimum size that can be specified is 128 Kbytes. The trace file can be thought of as a least recently used circular buffer. Once the file has been filled, newer events will overwrite the older ones.

Grammar Probes are specified by a list of space-separated selectors. Selectors are of the form:

attribute=value

(See `TNF_PROBE(3TNF)`). The “*attribute=*” is optional. If it is not specified, it defaults to “*keys=*”.

The *attribute* or *value* (generically called “*spec*”) can be any of the following:

- IDENT** Any sequence of letters, digits, `_`, `\`, `.`, `%` not beginning with a digit. **IDENT** implies an exact match.
- QUOTED_STR** Usually used to escape reserved words (any commands in the command language). **QUOTED_STR** implies an exact match and has to be enclosed in single quotes (`'`).
- REGEXP** An `ed(1)` regular expression pattern match. **REGEXP** has to be enclosed in slashes (`/ /`). A `/` can be included in a **REGEXP** by escaping it with a backslash `\`.

The following grammar explains the syntax.

```
selector_list ::= | /* empty */
                selector_list selector
selector ::=    spec=spec | /* whitespace around '=' opt */
                spec
spec ::=       IDENT |
                QUOTED_STR |
                REGEXP
```

The terminals in the above grammar are:

prex(1)

```
IDENT =      [a-zA-Z_\.\%]{[a-zA-Z0-9_\.\%]}+
QUOTED_STR = '[^\n]*' /* any string in single quotes */
REGEXP =     /^[^\n]*/ /* regexp's have to be in / / */
```

This is a list of the remaining grammar that is needed to understand the syntax of the command language (defined in next subsection):

```
filename ::= QUOTED_STR /* QUOTED_STR defined above */
spec_list ::= /* empty */ |
            spec_list spec /* spec defined above */
fcn_handle ::= &IDENT /* IDENT defined above */
set_name ::= $IDENT /* IDENT defined above */
```

Command Language

1. Set Creation and Set Listing

```
create $set_name selector_list
```

```
list sets # list the defined sets
```

create can be used to define a set which contains probes that match the *selector_list*. The set `$all` is pre-defined as `/* */` and it matches all the probes.

2. Function Listing

```
list fcns # list the available fcn_handle
```

The user can list the different functions that can be connected to probe points. Currently, only the debug function called `&debug` is available.

3. Commands to Connect and Disconnect Probe Functions

```
connect &fcn_handle $set_name
connect &fcn_handle selector_list
clear $set_name
```

```
clear selector_list
```

The `connect` command is used to connect probe functions (which must be prefixed by `&`) to probes. The probes are specified either as a single set (with a `$`), or by explicitly listing the probe selectors in the command. The probe function has to be one that is listed by the `list fcns` command. This command does not enable the probes. The `clear` command is used to disconnect all connected probe functions from the specified probes.

4. Commands to Toggle the Tracing Mode

```
trace $set_name
trace selector_list
untrace $set_name
```

```
untrace selector_list
```

The `trace` and `untrace` commands are used to toggle the tracing action of a probe point (that is, whether a probe will emit a trace record or not if it is hit). This command does not enable the probes specified. Probes have tracing on by default. The most efficient way to turn off tracing is by using the `disable` command. `untrace` is useful if you want debug output but no tracing. If so, set the state of the probe to enabled, untraced, and the debug function connected.

5. Commands to Enable and Disable Probes

```
enable $set_name
enable selector_list
disable $set_name
```

disable selector_list The `enable` and `disable` commands are used to control whether the probes perform the action that they have been set up for. To trace a probe, it has to be both enabled and traced (using the `trace` command). Probes are disabled by default. The `list history` command is used to list the probe control commands issued: `connect`, `clear`, `trace`, `untrace`, `enable`, and `disable`. These are the commands that are executed whenever a new shared object is brought in to the target program by `dlopen(3DL)`. See the subsection, `dlopen'ed Libraries`, below for more information. The following table shows the actions that result from specific combinations of tracing, enabling, and connecting:

Enabled or Disabled	Tracing State (On/Off)	Debug State (Connected/Cleared)	Results In
Enabled	On	Connected	Tracing and Debugging
Enabled	On	Cleared	Tracing only
Enabled	Off	Connected	Debugging only
Enabled	Off	Cleared	Nothing
Disabled	On	Connected	Nothing
Disabled	On	Cleared	Nothing
Disabled	Off	Connected	Nothing
Disabled	Off	Cleared	Nothing

6. List History

```
list history # lists probe control command history
```

The `list history` command displays a list of the probe control commands previously issued in the tracing session, for example, `connect`, `clear`, `trace`, `disable`. Commands in the history list are executed wherever a new shared object is brought into the target program by `dlopen(3DL)`.

7. Commands to List Probes, List Values, or List Trace File Name

```
list spec_list probes $set_name # list probes $all
list spec_list probes selector_list # list name probes file=test.c
list values spec_list # list values keys given in spec_list
list tracefile # list tracefile
```

The first two commands list the

prex(1)

selected attributes and values of the specified probes. They can be used to check the state of a probe. The third command lists the various values associated with the selected attributes. The fourth command lists the current tracefile.

8. Help Command

help *topic* To get a list of the help topics that are available, invoke the **help** command with no arguments. If a *topic* argument is specified, help is printed for that topic.

9. Source a File

source *filename* The **source** command can be used to source a file of **prex** commands. **source** can be nested (that is, a file can source another file). *filename* is a quoted string.

10. Process Control

```
continue          # resumes the target process
quit kill          # quit prex, kill target
quit resume       # quit prex, continue target
quit suspend      # quit prex, leave target suspended
quit              # quit prex (continue or kill target)
```

The default **quit** will continue the target process if **prex** attached to it. Instead, if **prex** had started the target program, **quit** will kill the target process.

dlopen'ed Libraries

Probes in shared objects that are brought in by **dlopen(3DL)** are automatically set up according to the command history of **prex**. When a shared object is removed by a **dldclose(3DL)**, **prex** again needs to refresh its understanding of the probes in the target program. This implies that there is more work to do for **dlopen(3DL)** and **dldclose(3DL)**—so they will take slightly longer. If a user is not interested in this feature and doesn't want to interfere with **dlopen(3DL)** and **dldclose(3DL)**, detach **prex** from the target to inhibit this feature.

Signals to Target Program

prex does not interfere with signals that are delivered directly to the target program. However, **prex** receives all signals normally generated from the terminal, for example, Control-C (**SIGINT**), and Control-Z (**SIGSTOP**), and does not forward them to the target program. To signal the target program, use the **kill(1)** command from a shell.

Interactions with Other Applications

Process managing applications like **dbx**, **truss(1)**, and **prex** cannot operate on the same target program simultaneously. **prex** will not be able to attach to a target which is being controlled by another application. A user can trace and debug a program serially by the following method: first attach **prex** to target (or start target through **prex**), set up the probes using the command language, and then type **quit** suspend. The user can then attach **dbx** to the suspended process and debug it. A user

	<p>can also suspend the target by sending it a SIGSTOP signal, and then by typing <code>quit</code> resume to <code>prex</code>. In this case, the user should also send a SIGCONT signal after invoking <code>dbx</code> on the stopped process (else <code>dbx</code> will be hung).</p>
<p>Failure of Event Writing Operations</p>	<p>There are a few failure points that are possible when writing out events to a trace file, for example, system call failures. These failures result in a failure code being set in the target process. The target process continues normally, but no trace records are written. Whenever a user enters Control-C to <code>prex</code> to get to a <code>prex</code> prompt, <code>prex</code> will check the failure code in the target and inform the user if there was a tracing failure.</p>
<p>Target Executing a Fork or exec</p>	<p>If the target program does a <code>fork(2)</code>, any probes that the child encounters will cause events to be logged to the same trace file. Events are annotated with a process id, so it will be possible to determine which process a particular event came from. In multi-threaded programs, there is a race condition with a thread doing a fork while the other threads are still running. For the trace file not to get corrupted, the user should either use <code>fork1(2)</code>, or make sure that all other threads are quiescent when doing a <code>fork(2)</code>.</p>
	<p>If the target program itself (not any children it may <code>fork(2)</code>) does an <code>exec(2)</code>, <code>prex</code> detaches from the target and exits. The user can reconnect <code>prex</code> with <code>prex -p pid</code>.</p> <p>A <code>vfork(2)</code> is generally followed quickly by an <code>exec(2)</code> in the child, and in the interim, the child borrows the parent's process while the parent waits for the <code>exec(2)</code>. Any events logged by the child from the parent process will appear to have been logged by the parent.</p>
<p>Kernel Mode</p>	<p>Invoking <code>prex</code> with the <code>-k</code> flag causes <code>prex</code> to run in kernel mode. In kernel mode, <code>prex</code> controls probes in the Solaris kernel. See <code>tnf_kernel_probes(4)</code> for a list of available probes in the Solaris kernel. A few <code>prex</code> commands are unavailable in kernel mode; many other commands are valid in kernel mode only.</p> <p>The <code>-l</code>, <code>-o</code>, and <code>-p</code> command-line options are not valid in kernel mode (that is, they may not be combined with the <code>-k</code> flag).</p> <p>The rest of this section describes the differences in the <code>prex</code> command language when running <code>prex</code> in kernel mode.</p> <ol style="list-style-type: none"> 1. <code>prex</code> will not stop the kernel <p>When <code>prex</code> attaches to a running user program, it stops the user program. Obviously, it cannot do this when attaching to the kernel. Instead, <code>prex</code> provides a "tracing master switch": no probes will have any effect unless the tracing master switch is on. This allows the user to iteratively select probes to enable, then enable them all at once by turning on the master switch.</p> <p>The command</p> <pre>ktrace [on off]</pre> <p>is used to inspect and set the value of the master switch. Without an argument, <code>prex</code> reports the current state of the master switch. Since <code>prex</code> will not stop or kill the kernel, the</p>

prex(1)

`quit resumeand`

`quit kill` commands are not valid in kernel mode.

2. No functions may be attached to probes in the kernel

In particular, the debug function is unavailable in kernel mode.

3. Trace output is written to an in-core buffer

In kernel mode, a trace output file is not generated directly, in order to allow probes to be placed in time-critical code. Instead, trace output is written to an in-core buffer, and copied out by a separate program, `tnfextract(1)`.

The in-core buffer is not automatically created. The following `prex` command controls buffer allocation and deallocation:

`buffer [alloc [size] | dealloc]` Without an argument, the `buffer` command reports the size of the currently allocated buffer, if any. With an argument of `alloc [size]`, `prex` allocates a buffer of the given size. *size* is in bytes, with an optional suffix of 'k' or 'm' specifying a multiplier of 1024 or 1048576, respectively. If no *size* is specified, the *size* specified on the command line with the `-s` option is used as a default. If the `-s` command line option was not used, the "default default" is 384 kilobytes. With an argument of `dealloc`, `prex` deallocates the trace buffer in the kernel. `prex` will reject attempts to turn the tracing master switch on when no buffer is allocated, and to deallocate the buffer when the tracing master switch is on. `prex` will refuse to allocate a buffer when one is already allocated; use `buffer dealloc` first. `prex` will not allocate a buffer larger than one-half of a machine's physical memory.

4. `prex` supports per-process probe enabling in the kernel

In kernel mode, it is possible to select a set of processes for which probes are enabled. No trace output will be written when other processes traverse these probe points. This is called "process filter mode". By default, process filter mode is off, and all processes cause the generation of trace records when they hit an enabled probe.

Some kernel events such as interrupts cannot be associated with a particular user process. By convention, these events are considered to be generated by process id 0.

`prex` provides commands to turn process filter mode on and off, to get the current status of the process filter mode switch, to add and delete processes (by process id) from the process filter set, and to list the current process filter set.

The process filter set is maintained even when process filter mode is off, but has no effect unless process filter mode is on.

When a process in the process filter set exits, its process id is automatically deleted from the process filter set.

The command:

prex(1)

`pfilter [on | off | add pidlist | delete pidlist]` controls the process filter switch, and process filter set membership. With no arguments, `pfilter` prints the current process filter set and the state of the process filter mode switch:

`on` or `off` set the state of the process filter mode switch.

`add pidlist`

`delete pidlist` add or delete processes from the process filter set. *pidlist* is a comma-separated list of one or more process ids.

EXAMPLES See `tracing(3TNF)` for complete examples showing, among other things, the use of `prex` to do simple probe control.

When either the process or kernel is started, all probes are disabled.

EXAMPLE 1 Set creation and set listing

```
create $out name=/out/        # $out = probes with "out" in
                              # value of "name" attribute
create $foo /page/ name=biodone # $foo = union of
                              # probes with "page" in value of keys attribute
                              # probes with "biodone" as value of "name" attribute
list sets                    # list the defined sets
list fcns                    # list the defined probe fcns
```

EXAMPLE 2 Commands to trace and connect probe functions

```
trace foobar='on'            # exact match on foobar attribute
trace $all                   # trace all probes (predefined set $all)
connect &debug $foo         # connect debug func to probes in $foo
```

EXAMPLE 3 Commands to enable and disable probes

```
enable $all                  # enable all probes
enable /vm/ name=alloc       # enable the specified probes
disable $foo                 # disable probes in set $foo
list history                 # list probe control commands issued
```

EXAMPLE 4 Process control

```
continue                    # resumes the target process
^C                           # stop target; give control to prex
quit resume                 # exit prex, leave process running
                              # and resume execution of program
```

EXAMPLE 5 Kernel mode

```
buffer alloc 2m             # allocate a 2 Megabyte buffer
enable $all                 # enable all probes
trace $all                  # trace all probes
ktrace on                    # turn tracing on
ktrace off                  # turn tracing back off
```

prex(1)

EXAMPLE 5 Kernel mode (Continued)

```

pfilter on           # turn process filter mode on
pfilter add 1379     # add pid 1379 to process filter
ktrace on           # turn tracing on
                   # (only pid 1379 will be traced)

```

FILES

.prexrc local prex initialization file

~/.prexrc user's prex initialization file

/proc/*nnnnn* process files

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtnfc (32-bit) SUNWtnfcx (64-bit)

SEE ALSO ed(1), kill(1), ksh(1), ld(1), tnfdump(1), tnfextract(1), truss(1), exec(2), fork(2), fork1(2), vfork(2), TNF_DECLARE_RECORD(3TNF), TNF_PROBE(3TNF), dlclose(3DL), dlopen(3DL), gethrtime(3C), libtnfctl(3TNF), tnf_process_disable(3TNF), tracing(3TNF), tnf_kernel_probes(4), attributes(5)

NOTES Currently, the only probe function that is available is the &debug function. When this function is executed, it prints out the arguments sent in to the probe as well as the value associated with the sunw%debug attribute in the detail field (if any) to stderr.

For example, for the following probe point:

```

TNF_PROBE_2(input_values, "testapp main",
            "sunw%debug 'have read input values successfully'",
            tnf_long, int_input, x,
            tnf_string, string_input, input);

```

If *x* was 100 and *input* was the string "success", then the output of the debug probe function would be:

```

probe input_values; sunw%debug "have read input values successfully";
int_input=100; string_input="success";

```

Some non-SPARC hardware lacks a true high-resolution timer, causing gethrtime() to return the same value multiple times in succession. This can lead to problems in how some tools interpret the trace file. This situation can be improved by interposing a version of gethrtime(), which causes these successive values to be artificially incremented by one nanosecond:

```

hrtime_t
gethrtime()
{
    static mutex_t lock;
    static hrtime_t (*real_gethrtime)(void) = NULL;
    static hrtime_t last_time = 0;

    hrtime_t this_time;

    if (real_gethrtime == NULL) {
        real_gethrtime =
            (hrtime_t (*)(void)) dlsym(RTLD_NEXT, "gethrtime");
    }
    this_time = real_gethrtime();

    mutex_lock(&lock);
    if (this_time <= last_time)
        this_time = ++last_time;
    else
        last_time = this_time;
    mutex_unlock(&lock);

    return (this_time);
}

```

Of course, this does not increase the resolution of the timer, so timestamps for individual events are still relatively inaccurate. But this technique maintains ordering, so that if event A causes event B, B never appears to happen before or at the same time as A.

dbx is available with the Sun Workshop Products.

BUGS prex should issue a notification when a process id has been automatically deleted from the filter set.

There is a known bug in prex which can result in this message:

```

Tracing shut down in target program due to an internal
error - Please restart prex and target

```

When prex runs as root, and the target process is not root, and the tracefile is placed in a directory where it cannot be removed and re-created (a directory with the sticky bit on, like /tmp), then the target process will not be able to open the tracefile when it needs to. This results in tracing being disabled.

Changing any of the circumstances listed above should fix the problem. Either don't run prex as root, or run the target process as root, or specify the tracefile in a directory other than /tmp.

print(1)

NAME	print – shell built-in function to output characters to the screen or window				
ksh	print [-Rnrpsu [<i>n</i>]] [<i>arg</i> ...]				
ksh	The shell output mechanism. With no flags or with flag <code>-</code> or <code>-</code> , the arguments are printed on standard output as described by <code>echo(1)</code> .				
OPTIONS	The following options are supported: <ul style="list-style-type: none"><code>-n</code> suppresses new-line from being added to the output.<code>-R</code><code>-r</code> (raw mode) ignore the escape conventions of <code>echo</code>. The <code>-R</code> option will print all subsequent arguments and options other than <code>-n</code>.<code>-p</code> causes the arguments to be written onto the pipe of the process spawned with <code> &</code> instead of standard output.<code>-s</code> causes the arguments to be written onto the history file instead of standard output.<code>-u [<i>n</i>]</code> flag can be used to specify a one digit file descriptor unit number <i>n</i> on which the output will be placed. The default is 1.				
EXIT STATUS	The following exit values are returned: <ul style="list-style-type: none">0 Successful operation.>0 Output file is not open for writing.

DIAGNOSTICS	If a <i>variable</i> is specified and it is not defined in the environment, printenv returns an exit status of 1.				

printf(1)

NAME	printf – write formatted output
SYNOPSIS	printf <i>format</i> [<i>argument...</i>]
DESCRIPTION	The <code>printf</code> command writes formatted operands to the standard output. The <i>argument</i> operands are formatted under control of the <i>format</i> operand.
OPERANDS	<p>The following operands are supported:</p> <p><i>format</i></p> <p>A string describing the format to use to write the remaining operands. The <i>format</i> operand is used as the <i>format</i> string described on the <code>formats(5)</code> manual page, with the following exceptions:</p> <ul style="list-style-type: none">■ A SPACE character in the format string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output.■ A character in the format string is treated as a character, not as a SPACE character.■ In addition to the escape sequences described on the <code>formats(5)</code> manual page (<code>\\</code>, <code>\a</code>, <code>\b</code>, <code>\f</code>, <code>\n</code>, <code>\r</code>, <code>\t</code>, <code>\v</code>), <code>\ddd</code>, where <i>ddd</i> is a one-, two- or three-digit octal number, is written as a byte with the numeric value specified by the octal number.■ The program does not precede or follow output from the <code>d</code> or <code>u</code> conversion specifications with blank characters not specified by the <i>format</i> operand.■ The program does not precede output from the <code>o</code> conversion specification with zeros not specified by the <i>format</i> operand.■ An additional conversion character, <code>b</code>, is supported as follows. The argument is taken to be a string that may contain backslash-escape sequences. The following backslash-escape sequences are supported:<ul style="list-style-type: none">– the escape sequences listed on the <code>formats(5)</code> manual page (<code>\\</code>, <code>\a</code>, <code>\b</code>, <code>\f</code>, <code>\n</code>, <code>\r</code>, <code>\t</code>, <code>\v</code>), which are converted to the characters they represent– <code>\0ddd</code>, where <i>ddd</i> is a zero-, one-, two- or three-digit octal number that is converted to a byte with the numeric value specified by the octal number– <code>\c</code>, which is written and causes <code>printf</code> to ignore any remaining characters in the string operand containing it, any remaining string operands and any additional characters in the <i>format</i> operand. <p>The interpretation of a backslash followed by any other sequence of characters is unspecified.</p> <p>Bytes from the converted string are written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it is taken to be</p>

infinite, so all bytes up to the end of the converted string are written. For each specification that consumes an argument, the next argument operand is evaluated and converted to the appropriate type for the conversion as specified below. The *format* operand is reused as often as necessary to satisfy the argument operands. Any extra *c* or *s* conversion specifications are evaluated as if a null string argument were supplied; other extra conversion specifications are evaluated as if a zero argument were supplied. If the *format* operand contains no conversion specifications and *argument* operands are present, the results are unspecified. If a character sequence in the *format* operand begins with a % character, but does not form a valid conversion specification, the behavior is unspecified.

argument

The strings to be written to standard output, under the control of *format*. The *argument* operands are treated as strings if the corresponding conversion character is *b*, *c* or *s*. Otherwise, it is evaluated as a C constant, as described by the ISO C standard, with the following extensions:

- A leading plus or minus sign is allowed.
- If the leading character is a single- or double-quote, the value is the numeric value in the underlying codeset of the character following the single- or double-quote.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does not exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

USAGE Notice that this `printf` utility, like the `printf(3C)` function on which it is based, makes no special provision for dealing with multi-byte characters when using the `%c` conversion specification or when a precision is specified in a `%b` or `%s` conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.

Field widths and precisions cannot be specified as `*`.

For compatibility with previous versions of SunOS 5.x, the `$` format specifier is supported for formats containing *only* `%s` specifiers.

The `%b` conversion specification is not part of the ISO C standard; it has been added here as a portable way to process backslash escapes expanded in string operands as provided by the `echo` utility. See also the USAGE section of the `echo(1)` manual page for ways to use `printf` as a replacement for all of the traditional versions of the `echo` utility.

printf(1)

If an argument cannot be parsed correctly for the corresponding conversion specification, the `printf` utility reports an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion are to be reported as errors.

It is not considered an error if an argument operand is not completely used for a `c` or `s` conversion or if a string operand's first or second character is used to get the numeric value of a character.

EXAMPLES

EXAMPLE 1 Printing a series of prompts

To alert the user and then print and read a series of prompts:

```
example% printf "\aPlease fill in the following: \nName: "  
read name  
printf "Phone number: "  
read phone
```

EXAMPLE 2 Printing a table of calculations

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single tab character. The percentage is written to one decimal place of accuracy:

```
example% while read right wrong ; do  
  percent=$(echo "scale=1; ($right*100)/($right+$wrong)" | bc)  
  printf "%2d right\t%2d wrong\t(%%s%%)\n" \  
    $right $wrong $percent  
done < database_file
```

EXAMPLE 3 Printing number strings

The command:

```
example% printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:

```
      1  21  
     3214321  
54321   0
```

Notice that the *format* operand is used three times to print all of the given strings and that a 0 was supplied by `printf` to satisfy the last `%4d` conversion specification.

EXAMPLE 4 Tabulating conversion errors

The `printf` utility tells the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when `%d` is specified as the *format* operand:

EXAMPLE 4 Tabulating conversion errors *(Continued)*

Arguments	Standard	Diagnostic
5a	5	printf: 5a not completely converted
9999999999	2147483647	printf: 9999999999: Results too large
-9999999999	-2147483648	printf: -9999999999: Results too large
ABC	0	printf: ABC expected numeric value

Notice that the value shown on standard output is what would be expected as the return value from the function `strtol(3C)`. A similar correspondence exists between `%u` and `strtoul(3C)`, and `%e`, `%f` and `%g` and `strtod(3C)`.

EXAMPLE 5 Printing output for a specific locale

In a locale using the ISO/IEC 646:1991 standard as the underlying codeset, the command:

```
example% printf "%d\n" 3 +3 -3 \'3 \'+3 \'-3"
```

produces:

3	Numeric value of constant 3
3	Numeric value of constant 3
-3	Numeric value of constant -3
51	Numeric value of the character '3' in the ISO/IEC 646:1991 standard codeset
43	Numeric value of the character '+' in the ISO/IEC 646:1991 standard codeset
45	Numeric value of the character '-' in the SO/IEC 646:1991 standard codeset

Notice that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the `wchar_t` representation of the character.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

**ENVIRONMENT
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `printf`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, and `NLSPATH`.

printf(1)

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc
CSI	enabled
Interface Stability	Standard

SEE ALSO `awk(1)`, `bc(1)`, `echo(1)`, `printf(3C)`, `strtod(3C)`, `strtol(3C)`, `strtoul(3C)`, `attributes(5)`, `environ(5)`, `formats(5)`, `standards(5)`

NAME	prioctl – display or set scheduling parameters of specified process(es)
SYNOPSIS	<pre>prioctl -l prioctl -d [-i <i>idtype</i>] [<i>idlist</i>] prioctl -s [-c <i>class</i>] [<i>class-specific options</i>] [-i <i>idtype</i>] [<i>idlist</i>] prioctl -e [-c <i>class</i>] [<i>class-specific options</i>] <i>command</i> [<i>argument(s)</i>]</pre>
DESCRIPTION	<p>The <code>prioctl</code> command displays or sets scheduling parameters of the specified process(es). It can also be used to display the current configuration information for the system's process scheduler or execute a command with specified scheduling parameters.</p> <p>Processes fall into distinct classes with a separate scheduling policy applied to each class. The process classes currently supported are the real-time class, time-sharing class, interactive class, fair-share class, and the fixed priority class. The characteristics of these classes and the class-specific options they accept are described below in the USAGE section under the headings <i>Real-Time Class</i>, <i>Time-Sharing Class</i>, <i>Inter-Active Class</i>, <i>Fair-Share Class</i>, and <i>Fixed-Priority Class</i>. With appropriate permissions, the <code>prioctl</code> command can change the class and other scheduling parameters associated with a running process.</p> <p>In the default configuration, a runnable real-time process runs before any other process. Therefore, inappropriate use of real-time processes can have a dramatic negative impact on system performance.</p> <p>If an <i>idlist</i> is present, it must appear last on the command line and the elements of the list must be separated by white space. If no <i>idlist</i> is present, an <i>idtype</i> argument of <code>pid</code>, <code>ppid</code>, <code>pgid</code>, <code>sid</code>, <code>taskid</code>, <code>class</code>, <code>uid</code>, <code>gid</code>, or <code>projid</code> specifies the process ID, parent process ID, process group ID, session ID, task ID, class, user ID, group ID, or project ID, respectively, of the <code>prioctl</code> command itself.</p> <p>The command</p> <pre>prioctl -d [-i <i>idtype</i>] [<i>idlist</i>]</pre> <p>displays the class and class-specific scheduling parameters of the process(es) specified by <i>idtype</i> and <i>idlist</i>.</p> <p>The command</p> <pre>prioctl -s [-c <i>class</i>] [<i>class-specific options</i>] \ [-i <i>idtype</i>] [<i>idlist</i>]</pre> <p>sets the class and class-specific parameters of the specified processes to the values given on the command line. The <code>-c class</code> option specifies the class to be set. (The valid <i>class</i> arguments are RT for real-time, TS for time-sharing, IA for inter-active, FSS for fair-share, or FX for fixed-priority.)</p>

priocntl(1)

The class-specific parameters to be set are specified by the class-specific options as explained under the appropriate heading below. If the `-c class` option is omitted, *idtype* and *idlist* must specify a set of processes which are all in the same class, otherwise an error results. If no class-specific options are specified, the process's class-specific parameters are set to the default values for the class specified by `-c class` (or to the default parameter values for the process's current class if the `-c class` option is also omitted).

In order to change the scheduling parameters of a process using `priocntl` the real or effective user ID (respectively, groupID) of the user invoking `priocntl` must match the real or effective user ID (respectively, groupID) of the receiving process or the effective user ID of the user must be super-user. These are the minimum permission requirements enforced for all classes. An individual class may impose additional permissions requirements when setting processes to that class or when setting class-specific scheduling parameters.

When *idtype* and *idlist* specify a set of processes, `priocntl` acts on the processes in the set in an implementation-specific order. If `priocntl` encounters an error for one or more of the target processes, it may or may not continue through the set of processes, depending on the nature of the error.

If the error is related to permissions, `priocntl` prints an error message and then continues through the process set, resetting the parameters for all target processes for which the user has appropriate permissions. If `priocntl` encounters an error other than permissions, it does not continue through the process set but prints an error message and exits immediately.

A special `sys` scheduling class exists for the purpose of scheduling the execution of certain special system processes (such as the swapper process). It is not possible to change the class of any process to `sys`. In addition, any processes in the `sys` class that are included in the set of processes specified by *idtype* and *idlist* are disregarded by `priocntl`. For example, if *idtype* were `uid`, an *idlist* consisting of a zero would specify all processes with a UID of 0, except processes in the `sys` class and (if changing the parameters using the `-s` option) the `init` process.

The `init` process (process ID 1) is a special case. In order for the `priocntl` command to change the class or other scheduling parameters of the `init` process, *idtype* must be `pid` and *idlist* must consist of only a 1. The `init` process may be assigned to any class configured on the system, but the time-sharing class is almost always the appropriate choice. (Other choices may be highly undesirable; see the *System Administration Guide: Basic Administration* for more information.)

The command

```
priocntl -e [-c class] [class-specific options] command \  
[argument . . .]
```

executes the specified command with the class and scheduling parameters specified on the command line (*arguments* are the arguments to the command). If the `-c class` option is omitted the command is run in the user's current class.

OPTIONS The following options are supported:

- c *class* Specifies the *class* to be set. (The valid *class* arguments are RT for real-time, TS for time-sharing, IA for inter-active, FSS for fair-share, or FX for fixed-priority.) If the specified class is not already configured, it will be automatically configured.
- d Displays the scheduling parameters associated with a set of processes.
- e Executes a specified command with the class and scheduling parameters associated with a set of processes.
- i *idtype* This option, together with the *idlist* arguments (if any), specifies one or more processes to which the `prioctl` command is to apply. The interpretation of *idlist* depends on the value of *idtype*. The valid *idtype* arguments and corresponding interpretations of *idlist* are as follows:
 - i pid *idlist* is a list of process IDs. The `prioctl` command applies to the specified processes.
 - i ppid *idlist* is a list of parent process IDs. The `prioctl` command applies to all processes whose parent process ID is in the list.
 - i pgid *idlist* is a list of process group IDs. The `prioctl` command applies to all processes in the specified process groups.
 - i sid *idlist* is a list of session IDs. The `prioctl` command applies to all processes in the specified sessions.
 - i taskid *idlist* is a list of task IDs. The `prioctl` command applies to all processes in the specified tasks.
 - i class *idlist* consists of a single class name (RT for real-time, TS for time-sharing, IA for inter-active, FSS for fair-share, or FX for fixed-priority). The `prioctl` command applies to all processes in the specified class.
 - i uid *idlist* is a list of user IDs. The `prioctl` command applies to all processes with an effective user ID equal to an ID from the list.
 - i gid *idlist* is a list of group IDs. The `prioctl` command applies to all processes with an effective group ID equal to an ID from the list.

priocntl(1)

	<code>-i projid</code>	<i>idlist</i> is a list of project IDs. The <code>priocntl</code> command applies to all processes with an effective project ID equal to an ID from the list.
	<code>-i all</code>	The <code>priocntl</code> command applies to all existing processes. No <i>idlist</i> should be specified (if one is specified, it is ignored). The permission restrictions described below still apply.
		If the <code>-i idtype</code> option is omitted when using the <code>-d</code> or <code>-s</code> options the default <i>idtype</i> of <code>pid</code> is assumed.
<code>-l</code>		Displays a list of the classes currently configured in the system along with class-specific information about each class. The format of the class-specific information displayed is described under <code>USAGE</code> .
<code>-s</code>		Sets the scheduling parameters associated with a set of processes.
		The valid class-specific options for setting real-time parameters are:
	<code>-p rtpri</code>	Sets the real-time priority of the specified process(es) to <i>rtpri</i> .
	<code>-t tqntm [-r res]</code>	Sets the time quantum of the specified process(es) to <i>tqntm</i> . You may optionally specify a resolution as explained below.
	<code>-q tqsig</code>	Sets the real-time time quantum signal of the specified process(es) to <i>tqsig</i> .
		The valid class-specific options for setting time-sharing parameters are:
	<code>-m tsuprilim</code>	Sets the user priority limit of the specified process(es) to <i>tsuprilim</i> .
	<code>-p tsupri</code>	Sets the user priority of the specified process(es) to <i>tsupri</i> .
		The valid class-specific options for setting inter-active parameters are:
	<code>-m iauprilim</code>	Sets the user priority limit of the specified process(es) to <i>iauprilim</i> .
	<code>-p iaupri</code>	Sets the user priority of the specified process(es) to <i>iaupri</i> .
		The valid class-specific options for setting fair-share parameters are:
	<code>-m fssuprilim</code>	Sets the user priority limit of the specified process(es) to <i>fssuprilim</i> .
	<code>-p fssupri</code>	Sets the user priority of the specified process(es) to <i>fssupri</i> .
		The valid class-specific options for setting fixed-priority parameters are:
	<code>-m fxuprilim</code>	Sets the user priority limit of the specified process(es) to <i>fxuprilim</i> .
	<code>-p fxupri</code>	Sets the user priority of the specified process(es) to <i>fxupri</i> .

`-t tqntm` `[-r res]` Sets the time quantum of the specified process(es) to *tqntm*. You may optionally specify a resolution as explained below.

Real-Time Class

The real-time class provides a fixed priority preemptive scheduling policy for those processes requiring fast and deterministic response and absolute user/application control of scheduling priorities. If the real-time class is configured in the system, it should have exclusive control of the highest range of scheduling priorities on the system. This ensures that a runnable real-time process is given CPU service before any process belonging to any other class.

The real-time class has a range of real-time priority (*rtpri*) values that may be assigned to processes within the class. Real-time priorities range from 0 to *x*, where the value of *x* is configurable and can be displayed for a specific installation that has already configured a real-time scheduler, by using the command

```
priocntl -l
```

The real-time scheduling policy is a fixed priority policy. The scheduling priority of a real-time process never changes except as the result of an explicit request by the user/application to change the *rtpri* value of the process.

For processes in the real-time class, the *rtpri* value is, for all practical purposes, equivalent to the scheduling priority of the process. The *rtpri* value completely determines the scheduling priority of a real-time process relative to other processes within its class. Numerically higher *rtpri* values represent higher priorities. Since the real-time class controls the highest range of scheduling priorities in the system, it is guaranteed that the runnable real-time process with the highest *rtpri* value is always selected to run before any other process in the system.

In addition to providing control over priority, `priocntl` provides for control over the length of the time quantum allotted to processes in the real-time class. The time quantum value specifies the maximum amount of time a process may run, assuming that it does not complete or enter a resource or event wait state (`sleep`). Notice that if another process becomes runnable at a higher priority, the currently running process may be preempted before receiving its full time quantum.

The command

```
priocntl -d [-i idtype] [idlist]
```

displays the real-time priority, time quantum (in millisecond resolution), and time quantum signal value for each real-time process in the set specified by *idtype* and *idlist*.

Any combination of the `-p`, `-t [-r]`, and `-q` options may be used with `priocntl -s` or `priocntl -e` for the real-time class. If an option is omitted and the process is currently real-time, the associated parameter is unaffected. If an option is omitted when changing the class of a process to real-time from some other class, the associated parameter is set to a default value. The default value for *rtpri* is 0 and the default for time quantum is dependent on the value of *rtpri* and on the system configuration; see `rt_dptbl(4)`.

priocntl(1)

When using the `-t tqntm` option, you may optionally specify a resolution using the `-r res` option. (If no resolution is specified, millisecond resolution is assumed.) If `res` is specified, it must be a positive integer between 1 and 1,000,000,000 inclusively and the resolution used is the reciprocal of `res` in seconds. For example, specifying `-t 10 -r 100` would set the resolution to hundredths of a second and the resulting time quantum length would be 10/100 seconds (one tenth of a second). Although very fine (nanosecond) resolution may be specified, the time quantum length is rounded up by the system to the next integral multiple of the system clock's resolution. Requests for time quanta of zero or quanta greater than the (typically very large) implementation-specific maximum quantum result in an error.

The real-time time quantum signal can be used to notify runaway real-time processes about the consumption of their time quantum. Those processes, which are monitored by the real-time time quantum signal, receive the configured signal in the event of time quantum expiration. The default value (0) of the time quantum signal `tqsig` will denote no signal delivery. A positive value will denote the delivery of the signal specified by the value. Like `kill(1)` and other commands operating on signals, the `-q tqsig` option is also able to handle symbolically named signals, like `XCPU` or `KILL`.

In order to change the class of a process to real-time (from any other class), the user invoking `priocntl` must have super-user privilege. In order to change the `rtpri` value or time quantum of a real-time process, the user invoking `priocntl` must either be super-user, or must currently be in the real-time class (shell running as a real-time process) with a real or effective user ID matching the real or effective user ID of the target process.

The real-time priority, time quantum, and time quantum signal are inherited across the `fork(2)` and `exec(2)` system calls. When using the time quantum signal with a user defined signal handler across the `exec(2)` system call, the new image must install an appropriate user defined signal handler before the time quantum expires. Otherwise, unpredictable behavior would result.

Time-Sharing Class

The time-sharing scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics. The objectives of the time-sharing policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs, while providing a degree of user/application control over scheduling.

The time-sharing class has a range of time-sharing user priority (`tsupri`) values that may be assigned to processes within the class. User priorities range from $-x$ to $+x$, where the value of x is configurable. The range for a specific installation can be displayed by using the command

```
priocntl -l
```

The purpose of the user priority is to provide some degree of user/application control over the scheduling of processes in the time-sharing class. Raising or lowering the `tsupri` value of a process in the time-sharing class raises or lowers the scheduling

priority of the process. It is not guaranteed, however, that a time-sharing process with a higher *tsupri* value will run before one with a lower *tsupri* value. This is because the *tsupri* value is just one factor used to determine the scheduling priority of a time-sharing process. The system may dynamically adjust the internal scheduling priority of a time-sharing process based on other factors such as recent CPU usage.

In addition to the system-wide limits on user priority (displayed with `prioctl -l`), there is a per process user priority limit (*tsuprilim*), which specifies the maximum *tsupri* value that may be set for a given process.

The command

```
prioctl -d [-i idtype] [idlist]
```

displays the user priority and user priority limit for each time-sharing process in the set specified by *idtype* and *idlist*.

Any time-sharing process may lower its own *tsuprilim* (or that of another process with the same user ID). Only a time-sharing process with super-user privilege may raise a *tsuprilim*. When changing the class of a process to time-sharing from some other class, super-user privilege is required in order to set the initial *tsuprilim* to a value greater than zero.

Any time-sharing process may set its own *tsupri* (or that of another process with the same user ID) to any value less than or equal to the process's *tsuprilim*. Attempts to set the *tsupri* above the *tsuprilim* (and/or set the *tsuprilim* below the *tsupri*) result in the *tsupri* being set equal to the *tsuprilim*.

Any combination of the `-m` and `-p` options may be used with `prioctl -s` or `prioctl -e` for the time-sharing class. If an option is omitted and the process is currently time-sharing, the associated parameter is normally unaffected. The exception is when the `-p` option is omitted and `-m` is used to set a *tsuprilim* below the current *tsupri*. In this case, the *tsupri* is set equal to the *tsuprilim* which is being set. If an option is omitted when changing the class of a process to time-sharing from some other class, the associated parameter is set to a default value. The default value for *tsuprilim* is 0 and the default for *tsupri* is to set it equal to the *tsuprilim* value which is being set.

The time-sharing user priority and user priority limit are inherited across the `fork(2)` and `exec(2)` system calls.

Inter-Active Class

The inter-active scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics while providing good responsiveness for user interaction. The objectives of the inter-active policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs. The priorities of processes in the inter-active class can be changed in the same manner as those in the time-sharing class, though the modified priorities will continue to be adjusted to provide good responsiveness for user interaction.

prionctl(1)

The inter-active user priority limit, *iaupri*, is equivalent to *tsupri*. The inter-active per process user priority, *iauprilim*, is equivalent to *tsuprilim*.

Inter-active class processes that have the *iamode* ("interactive mode") bit set are given a priority boost value of 10, which is factored into the user mode priority of the process when that calculation is made, that is, every time a process's priority is adjusted. This feature is used by the X windowing system, which sets this bit for those processes that run inside of the current active window to give them a higher priority.

Fair-Share Class

The fair-share scheduling policy provides a fair allocation of system CPU resources among projects, independent of the number of processes they own. Projects are given "shares" to control their entitlement to CPU resources. Resource usage is remembered over time, so that entitlement is reduced for heavy usage, and increased for light usage, with respect to other projects. CPU time is scheduled among processes according to their owner's entitlements, independent of the number of processes each project owns.

The FSS scheduling class supports the notion of per-process user priority and user priority limit for compatibility with the time-share scheduler. The fair share scheduler attempts to provide an evenly graded effect across the whole range of user priorities. Processes with positive *fssupri* values receive time slices less frequently than normal, while negative nice processes receive time slices more frequently than normal. Notice that user priorities do not interfere with shares. That is, changing a *fssupri* value of a process is not going to affect its project's overall CPU usage which only relates to the amount of shares it is allocated compared to other projects.

The priorities of processes in the fair-share class can be changed in the same manner as those in the time-share class.

Fixed-Priority Class

The fixed-priority class provides a fixed priority preemptive scheduling policy for those processes requiring that the scheduling priorities do not get dynamically adjusted by the system and that the user/application have control of the scheduling priorities.

The fixed-priority class shares the same range of scheduling priorities with the time-sharing class, by default. The fixed-priority class has a range of fixed-priority user priority (*fxupri*) values that may be assigned to processes within the class. User priorities range from 0 to *x*, where the value of *x* is configurable. The range for a specific installation can be displayed by using the command

```
prionctl -l
```

The purpose of the user priority is to provide user/application control over the scheduling of processes in the fixed-priority class. For processes in the fixed-priority class, the *fxupri* value is, for all practical purposes, equivalent to the scheduling priority of the process. The *fxupri* value completely determines the scheduling priority of a fixed-priority process relative to other processes within its class. Numerically higher *fxupri* values represent higher priorities.

In addition to the system-wide limits on user priority (displayed with `prioctl -l`), there is a per process user priority limit (*fxuprilm*), which specifies the maximum *fxupri* value that may be set for a given process.

Any fixed-priority process may lower its own *fxuprilm* (or that of another process with the same user ID). Only a process with super-user privilege may raise a *fxuprilm*. When changing the class of a process to fixed-priority from some other class, super-user privilege is required in order to set the initial *fxuprilm* to a value greater than zero.

Any fixed-priority process may set its own *fxupri* (or that of another process with the same user ID) to any value less than or equal to the process's *fxuprilm*. Attempts to set the *fxupri* above the *fxuprilm* (and/or set the *fxuprilm* below the *fxupri*) result in the *fxupri* being set equal to the *fxuprilm*.

In addition to providing control over priority, `prioctl` provides for control over the length of the time quantum allotted to processes in the fixed-priority class. The time quantum value specifies the maximum amount of time a process may run, before surrendering the CPU, assuming that it does not complete or enter a resource or event wait state (sleep). Notice that if another process becomes runnable at a higher priority, the currently running process may be preempted before receiving its full time quantum.

Any combination of the `-m`, `-p`, and `-t` options may be used with `prioctl -s` or `prioctl -e` for the fixed-priority class. If an option is omitted and the process is currently fixed-priority, the associated parameter is normally unaffected. The exception is when the `-p` option is omitted and the `-m` option is used to set a *fxuprilm* below the current *fxupri*. In this case, the *fxupri* is set equal to the *fxuprilm* which is being set. If an option is omitted when changing the class of a process to fixed-priority from some other class, the associated parameter is set to a default value. The default value for *fxuprilm* is 0. The default for *fxupri* is to set it equal to the *fxuprilm* value which is being set. The default for time quantum is dependent on the *fxupri* and on the system configuration. See `fx_dptbl(4)`.

The time quantum of processes in the fixed-priority class can be changed in the same manner as those in the real-time class.

The fixed-priority user priority, user priority limit, and time quantum are inherited across the `fork(2)` and `exec(2)` system calls.

EXAMPLES Real-Time Class examples follow:

EXAMPLE 1 Setting the class of any non-real-time processes

This example sets the class of any non-real-time processes selected by *idtype* and *idlist* to real-time and sets their real-time priority to the default value of 0. The real-time priorities of any processes currently in the real-time class are unaffected. The time quantum of all of the specified processes are set to 1/10 seconds.

priocntl(1)

EXAMPLE 1 Setting the class of any non-real-time processes (Continued)

```
example% priocntl -s -c RT -t 1 -r 10 -i idtype idlist
```

EXAMPLE 2 Executing a command in real-time

This example executes *command* in the real-time class with a real-time priority of 15 and a time quantum of 20 milliseconds:

```
example% priocntl -e -c RT -p 15 -t 20 command
```

EXAMPLE 3 Executing a command in real-time with a specified quantum signal

This example executes *command* in the real-time class with a real-time priority of 11, a time quantum of 250 milliseconds, and where the specified real-time quantum signal is SIGXCPU:

```
example% priocntl -e -c RT -p 11 -t 250 -q XCPU command
```

Time-Sharing Class examples follow:

EXAMPLE 4 Setting the class of non-time-sharing processes

This example sets the class of any non-time-sharing processes selected by *idtype* and *idlist* to time-sharing and sets both their user priority limit and user priority to 0. Processes already in the time-sharing class are unaffected.

```
example% priocntl -s -c TS -i idtype idlist
```

EXAMPLE 5 Executing a command in the time-sharing class

This example executes *command* with the arguments *arguments* in the time-sharing class with a user priority limit of 0 and a user priority of -15:

```
example% priocntl -e -c TS -m 0 -p -15 command [arguments]
```

EXAMPLE 6 Executing a command in fixed-priority class

This example executes a command in the fixed-priority class with a user priority limit of 20 and user priority of 10 and time quantum of 250 milliseconds:

```
example% priocntl -e -c FX -m 20 -p 10 -t 250 command
```

EXIT STATUS

The following exit values are returned:

For options -d, -l, and -s:

0 Successful operation.

1 Error condition.

For option -e:

Return of the Exit Status of the executed command denotes successful operation. Otherwise,

1 Command could not be executed at the specified priority.

ATTRIBUTES

DIAGNOSTICS

priocntl prints the following error messages:

Process(es) not found

None of the specified processes exists.

Specified processes from different classes

The -s option is being used to set parameters, the -c class option is not present, and processes from more than one class are specified.

Invalid option or argument

An unrecognized or invalid option or option argument is used.

proc(1)

NAME	proc, pflags, pcred, pldd, psig, pstack, pfiles, pwdx, pstop, prun, pwait, ptree, ptime – proc tools																
SYNOPSIS	<pre>/usr/bin/pflags [-r] [pid core...] /usr/bin/pcred [pid core...] /usr/bin/pldd [-F] [pid core...] /usr/bin/psig [-n] pid... /usr/bin/pstack [-F] [pid core...] /usr/bin/pfiles [-F] pid... /usr/bin/pwdx [-F] pid... /usr/bin/pstop pid... /usr/bin/prun pid... /usr/bin/pwait [-v] pid... /usr/bin/ptree [-a] [pid user...] /usr/bin/ptime command [arg...]</pre>																
DESCRIPTION	<p>The proc tools are utilities that exercise features of /proc (see proc(4)). Most of them take a list of process-ids (<i>pid</i>). The tools that do take process-ids also accept /proc/<i>nnn</i> as a process-id, so the shell expansion /proc/* can be used to specify all processes in the system.</p> <p>Some of the proc tools can also be applied to core files (see core(4)). The tools that apply to core files accept a list of either process IDs or names of core files or both.</p> <p>See WARNINGS.</p> <table><tr><td>pflags</td><td>Print the /proc tracing flags, the pending and held signals, and other /proc status information for each lwp in each process.</td></tr><tr><td>pcred</td><td>Print the credentials (effective, real, saved UIDs and GIDs) of each process.</td></tr><tr><td>pldd</td><td>List the dynamic libraries linked into each process, including shared objects explicitly attached using dlopen(3DL). See also ldd(1).</td></tr><tr><td>psig</td><td>List the signal actions and handlers of each process. See signal(3HEAD).</td></tr><tr><td>pstack</td><td>Print a hex+symbolic stack trace for each lwp in each process.</td></tr><tr><td>pfiles</td><td>Report fstat(2) and fcntl(2) information for all open files in each process.</td></tr><tr><td>pwdx</td><td>Print the current working directory of each process.</td></tr><tr><td>pstop</td><td>Stop each process (PR_REQUESTED stop).</td></tr></table>	pflags	Print the /proc tracing flags, the pending and held signals, and other /proc status information for each lwp in each process.	pcred	Print the credentials (effective, real, saved UIDs and GIDs) of each process.	pldd	List the dynamic libraries linked into each process, including shared objects explicitly attached using dlopen(3DL). See also ldd(1).	psig	List the signal actions and handlers of each process. See signal(3HEAD).	pstack	Print a hex+symbolic stack trace for each lwp in each process.	pfiles	Report fstat(2) and fcntl(2) information for all open files in each process.	pwdx	Print the current working directory of each process.	pstop	Stop each process (PR_REQUESTED stop).
pflags	Print the /proc tracing flags, the pending and held signals, and other /proc status information for each lwp in each process.																
pcred	Print the credentials (effective, real, saved UIDs and GIDs) of each process.																
pldd	List the dynamic libraries linked into each process, including shared objects explicitly attached using dlopen(3DL). See also ldd(1).																
psig	List the signal actions and handlers of each process. See signal(3HEAD).																
pstack	Print a hex+symbolic stack trace for each lwp in each process.																
pfiles	Report fstat(2) and fcntl(2) information for all open files in each process.																
pwdx	Print the current working directory of each process.																
pstop	Stop each process (PR_REQUESTED stop).																

prun	Set each process running (inverse of <code>pstop</code>).
pwait	Wait for all of the specified processes to terminate.
ptree	Print the process trees containing the specified <i>pids</i> or <i>users</i> , with child processes indented from their respective parent processes. An argument of all digits is taken to be a process-id, otherwise it is assumed to be a user login name. Default is all processes.
ptime	Time the <i>command</i> , like <code>time(1)</code> , but using microstate accounting for reproducible precision. Unlike <code>time(1)</code> , children of the command are not timed.

OPTIONS The following options are supported:

- a (ptree only) All. Includes children of process 0.
- F Force. Grabs the target process even if another process has control.
- n (psig only) Displays signal handler addresses rather than names.
- r (pflags only) If the process is stopped, displays its machine registers.
- v (pwait only) Verbose. Reports terminations to standard output.

USAGE These proc tools stop their target processes while inspecting them and reporting the results: `pfiles`, `pldd`, and `pstack`. A process can do nothing while it is stopped. Thus, for example, if the X server is inspected by one of these proc tools running in a window under the X server's control, the whole window system can become deadlocked because the proc tool would be attempting to print its results to a window that cannot be refreshed. Logging in from another system using `rlogin(1)` and killing the offending proc tool would clear up the deadlock in this case.

See WARNINGS.

Caution should be exercised when using the `-F` flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the proc tool in question.

Some of the proc tools can also be applied to core files, as shown by the synopsis above. A core file is a snapshot of a process's state and is produced by the kernel prior to terminating a process with a signal or by the `gcore(1)` utility. Some of the proc tools may need to derive the name of the executable corresponding to the process which dumped core or the names of shared libraries associated with the process. These files are needed, for example, to provide symbol table information for `pstack(1)`. If the proc tool in question is unable to locate the needed executable or shared library, some symbol information will be unavailable for display. Similarly, if a

proc(1)

core file from one operating system release is examined on a different operating system release, the run-time link-editor debugging interface (`librtld_db`) may not be able to initialize. In this case, symbol information for shared libraries will not be available.

EXIT STATUS The following exit values are returned:

0 Successful operation.
non-zero An error has occurred.

FILES `/proc/*` process files
`/usr/proc/lib/*` proc tools supporting files

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu (32-bit) SUNWesxu (64-bit)

SEE ALSO `gcore(1)`, `ldd(1)`, `pargs(1)`, `pgrep(1)`, `pkill(1)`, `plimit(1)`, `pmap(1)`, `preap(1)`, `ps(1)`, `pwd(1)`, `rlogin(1)`, `time(1)`, `truss(1)`, `wait(1)`, `fcntl(2)`, `fstat(2)`, `dlopen(3DL)`, `signal(3HEAD)`, `core(4)`, `proc(4)`, `attributes(5)`

WARNINGS The following `proc` tools stop their target processes while inspecting them and reporting the results: `pfiles`, `pldd`, `pmap`, and `pstack`.

A process can do nothing while it is stopped. Stopping a heavily used process in a production environment, even for a short amount of time, can cause severe bottlenecks and even hangs of these processes, causing them to be unavailable to users. Some databases could also terminate abnormally. Thus, for example, a database server under heavy load could hang when one of the database processes is traced using the above mentioned `proc` tools. Because of this, stopping a UNIX process in a production environment should be avoided.

A process being stopped by these tools can be identified by issuing `/usr/bin/ps -eflL` and looking for "T" in the first column. Notice that certain processes, for example "sched", can show the "T" status by default most of the time.

NAME	prof – display profile data
SYNOPSIS	prof [-ChsVz] [-a c n t] [-o x] [-g l] [-m <i>mdata</i>] [<i>prog</i>]
DESCRIPTION	The <code>prof</code> command interprets a profile file produced by the <code>monitor</code> function. The symbol table in the object file <i>prog</i> (<code>a.out</code> by default) is read and correlated with a profile file (<code>mon.out</code> by default). For each external text symbol the percentage of time spent executing between the address of that symbol and the address of the next is printed, together with the number of times that function was called and the average number of milliseconds per call.
OPTIONS	<p>The mutually exclusive options <code>-a</code>, <code>-c</code>, <code>-n</code>, and <code>-t</code> determine the type of sorting of the output lines:</p> <ul style="list-style-type: none"> <code>-a</code> Sort by increasing symbol address. <code>-c</code> Sort by decreasing number of calls. <code>-n</code> Sort lexically by symbol name. <code>-t</code> Sort by decreasing percentage of total time (default). <p>The mutually exclusive options <code>-o</code> and <code>-x</code> specify the printing of the address of each symbol monitored:</p> <ul style="list-style-type: none"> <code>-o</code> Print each symbol address (in octal) along with the symbol name. <code>-x</code> Print each symbol address (in hexadecimal) along with the symbol name. <p>The mutually exclusive options <code>-g</code> and <code>-l</code> control the type of symbols to be reported. The <code>-l</code> option must be used with care; it applies the time spent in a static function to the preceding (in memory) global function, instead of giving the static function a separate entry in the report. If all static functions are properly located, this feature can be very useful. If not, the resulting report may be misleading.</p> <p>Assume that <code>A</code> and <code>B</code> are global functions and only <code>A</code> calls static function <code>S</code>. If <code>S</code> is located immediately after <code>A</code> in the source code (that is, if <code>S</code> is properly located), then, with the <code>-l</code> option, the amount of time spent in <code>A</code> can easily be determined, including the time spent in <code>S</code>. If, however, both <code>A</code> and <code>B</code> call <code>S</code>, then, if the <code>-l</code> option is used, the report will be misleading; the time spent during <code>B</code>'s call to <code>S</code> will be attributed to <code>A</code>, making it appear as if more time had been spent in <code>A</code> than really had. In this case, function <code>S</code> cannot be properly located.</p> <ul style="list-style-type: none"> <code>-g</code> List the time spent in static (non-global) functions separately. The <code>-g</code> option function is the opposite of the <code>-l</code> function. <code>-l</code> Suppress printing statically declared functions. If this option is given, time spent executing in a static function is allocated to the closest global function loaded before the static function in the executable. This option is the default. It is the opposite of the <code>-g</code> function and should be used with care. <p>The following options may be used in any combination:</p>

prof(1)

- C Demangle C++ symbol names before printing them out.
- h Suppress the heading normally printed on the report. This is useful if the report is to be processed further.
- m *mdata* Use file *mdata* instead of *mon.out* as the input profile file.
- s Print a summary of several of the monitoring parameters and statistics on the standard error output.
- V Print *prof* version information on the standard error output.
- z Include all symbols in the profile range, even if associated with zero number of calls and zero time.

A program creates a profile file if it has been link edited with the `-p` option of `cc(1B)`. This option to the `cc(1B)` command arranges for calls to `monitor` at the beginning and end of execution. It is the call to `monitor` at the end of execution that causes the system to write a profile file. The number of calls to a function is tallied if the `-p` option was used when the file containing the function was compiled.

A single function may be split into subfunctions for profiling by means of the `MARK` macro. See `prof(5)`.

ENVIRONMENT VARIABLES

PROFDIR The name of the file created by a profiled program is controlled by the environment variable `PROFDIR`. If `PROFDIR` is not set, *mon.out* is produced in the directory current when the program terminates. If `PROFDIR=string, string/pid.progname` is produced, where *progname* consists of `argv[0]` with any path prefix removed, and *pid* is the process ID of the program. If `PROFDIR` is set, but null, no profiling output is produced.

FILES

mon.out default profile file
a.out default namelist (object) file

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

`cc(1B)`, `gprof(1)`, `exit(2)`, `pcsample(2)`, `profil(2)`, `malloc(3C)`, `malloc(3MALLOC)`, `monitor(3C)`, `attributes(5)`, `prof(5)`

NOTES

The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may "beat" with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.

Only programs that call `exit` or return from `main` are guaranteed to produce a profile file, unless a final call to `monitor` is explicitly coded.

The times for static functions are attributed to the preceding external text symbol if the `-g` option is not used. However, the call counts for the preceding function are still correct; that is, the static function call counts are not added to the call counts of the external function.

If more than one of the options `-t`, `-c`, `-a`, and `-n` is specified, the last option specified is used and the user is warned.

`LD_LIBRARY_PATH` must not contain `/usr/lib` as a component when compiling a program for profiling. If `LD_LIBRARY_PATH` contains `/usr/lib`, the program will not be linked correctly with the profiling versions of the system libraries in `/usr/lib/libp`. See `gprof(1)`.

Functions such as `mcount()`, `_mcount()`, `moncontrol()`, `_moncontrol()`, `monitor()`, and `_monitor()` may appear in the `prof` report. These functions are part of the profiling implementation and thus account for some amount of the runtime overhead. Since these functions are not present in an unprofiled application, time accumulated and call counts for these functions may be ignored when evaluating the performance of an application.

64-bit profiling

64-bit profiling may be used freely with dynamically linked executables, and profiling information is collected for the shared objects if the objects are compiled for profiling. Care must be applied to interpret the profile output, since it is possible for symbols from different shared objects to have the same name. If duplicate names are seen in the profile output, it is better to use the `-s` (summary) option, which prefixes a module id before each symbol that is duplicated. The symbols can then be mapped to appropriate modules by looking at the modules information in the summary.

If the `-a` option is used with a dynamically linked executable, the sorting occurs on a per-shared-object basis. Since there is a high likelihood of symbols from differed shared objects to have the same value, this results in an output that is more understandable. A blank line separates the symbols from different shared objects, if the `-s` option is given.

32-bit profiling

32-bit profiling may be used with dynamically linked executables, but care must be applied. In 32-bit profiling, shared objects cannot be profiled with `prof`. Thus, when a profiled, dynamically linked program is executed, only the "main" portion of the image is sampled. This means that all time spent outside of the "main" object, that is, time spent in a shared object, will not be included in the profile summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is profiled with `prof`. If desired, the program should be linked to the profiled version of a library (or to the standard

prof(1)

archive version if no profiling version is available), instead of the shared object to get profile information on the functions of a library. Versions of profiled libraries may be supplied with the system in the `/usr/lib/libp` directory. Refer to compiler driver documentation on profiling.

Consider an extreme case. A profiled program dynamically linked with the shared C library spends 100 units of time in some `libc` routine, say, `malloc()`. Suppose `malloc()` is called only from routine B and B consumes only 1 unit of time. Suppose further that routine A consumes 10 units of time, more than any other routine in the "main" (profiled) portion of the image. In this case, `prof` will conclude that most of the time is being spent in A and almost no time is being spent in B. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine B and not routine A. The value of the profiler in this case is severely degraded; the solution is to use archives as much as possible for profiling.

NAME	profiles – print execution profiles for a user
SYNOPSIS	profiles [-l] [user ...]
DESCRIPTION	<p>The <code>profiles</code> command prints on standard output the names of the execution profiles that have been assigned to you or to the optionally-specified user or role name. Profiles are a bundling mechanism used to enumerate the commands and authorizations needed to perform a specific function. Along with each listed executable are the process attributes, such as the effective user and group IDs, with which the process runs when started by a privileged command interpreter. The profile shells are <code>pf_csh</code>, <code>pf_ksh</code>, and <code>pf_eexec</code>. See the <code>pf_eexec(1)</code> man page. Profiles can contain other profiles defined in <code>prof_attr(4)</code>.</p> <p>Multiple profiles can be combined to construct the appropriate access control. When profiles are assigned, the authorizations are added to the existing set. If the same command appears in multiple profiles, the first occurrence, as determined by the ordering of the profiles, is used for process-attribute settings. For convenience, a wild card can be specified to match all commands.</p> <p>When profiles are interpreted, the profile list is loaded from <code>user_attr(4)</code>. If any default profile is defined in <code>/etc/security/policy.conf</code> (see <code>policy.conf(4)</code>), the list of default profiles will be added to the list loaded from <code>user_attr(4)</code>. Matching entries in <code>prof_attr(4)</code> provide the authorizations list, and matching entries in <code>exec_attr(4)</code> provide the commands list.</p>
OPTIONS	<p><code>-l</code> Lists the commands in each profile followed by the special process attributes such as user and group IDs.</p>
EXAMPLES	<p>EXAMPLE 1 Sample output</p> <p>The output of the <code>profiles</code> command has the following form:</p> <pre>example% profiles tester01 tester02 tester01 : Audit Management, All Commands tester02 : Device Management, All Commands example%</pre> <p>EXAMPLE 2 Using the list option</p> <pre>example% profiles -l tester01 tester02 tester01 : Audit Management: /usr/sbin/audit euid=root /usr/sbin/auditconfig euid=root egid=sys All Commands: * tester02 : Device Management: /usr/bin/allocate: euid=root /usr/bin/deallocate: euid=root All Commands * example%</pre>

ps(1)

NAME	ps – report process status
SYNOPSIS	ps [-aAcdefjLLPy] [-g <i>grplist</i>] [-n <i>namelist</i>] [-o <i>format</i>]... [-p <i>proclist</i>] [-s <i>sidlist</i>] [-t <i>term</i>] [-u <i>uidlist</i>] [-U <i>uidlist</i>] [-G <i>gidlist</i>]
DESCRIPTION	<p>The ps command prints information about active processes. Without options, ps prints information about processes that have the same effective user ID and the same controlling terminal as the invoker. The output contains only the process ID, terminal identifier, cumulative execution time, and the command name. Otherwise, the information that is displayed is controlled by the options.</p> <p>Some options accept lists as arguments. Items in a list can be either separated by commas or else enclosed in quotes and separated by commas or spaces. Values for <i>proclist</i> and <i>grplist</i> must be numeric.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Lists information about all processes most frequently requested: all those except session leaders and processes not associated with a terminal.-A Lists information for all processes. Identical to -e, below.-c Prints information in a format that reflects scheduler properties as described in <code>pricontrl(1)</code>. The -c option affects the output of the -f and -l options, as described below.-d Lists information about all processes except session leaders.-e Lists information about every process now running.-f Generates a full listing. (See below for significance of columns in a full listing.)-g <i>grplist</i> Lists only process data whose group leader's ID number(s) appears in <i>grplist</i>. (A group leader is a process whose process ID number is identical to its process group ID number.)-G <i>gidlist</i> Lists information for processes whose real group ID numbers are given in <i>gidlist</i>. The <i>gidlist</i> must be a single argument in the form of a blank- or comma-separated list.-j Prints session ID and process group ID.-l Generates a long listing. (See below.)-L Prints information about each light weight process (<i>lwp</i>) in each selected process. (See below.)-n <i>namelist</i> Specifies the name of an alternative system <i>namelist</i> file in place of the default. This option is accepted for compatibility, but is ignored.-o <i>format</i> Prints information according to the format specification given in <i>format</i>. This is fully described in <code>DISPLAY FORMATS</code>. Multiple -o

options can be specified; the format specification will be interpreted as the space-character-separated concatenation of all the *format* option-arguments.

- ps *proclist* Lists only process data whose process ID numbers are given in *proclist*.
- P Prints the number of the processor to which the process or lwp is bound, if any, under an additional column header, *PSR*.
- s *sidlist* Lists information on all session leaders whose IDs appear in *sidlist*.
- t *term* Lists only process data associated with *term*. Terminal identifiers are specified as a device file name, and an identifier. For example, *term/a*, or *pts/0*.
- u *uidlist* Lists only process data whose effective user ID number or login name is given in *uidlist*. In the listing, the numerical user ID will be printed unless you give the -f option, which prints the login name.
- U *uidlist* Lists information for processes whose real user ID numbers or login names are given in *uidlist*. The *uidlist* must be a single argument in the form of a blank- or comma-separated list.
- y Under a long listing (-l), omits the obsolete F and ADDR columns and includes an RSS column to report the resident set size of the process. Under the -y option, both RSS and SZ (see below) will be reported in units of kilobytes instead of pages.

Many of the options shown are used to select processes to list. If any are specified, the default list will be ignored and *ps* will select the processes represented by the inclusive OR of all the selection-criteria options.

DISPLAY FORMATS

Under the -f option, *ps* tries to determine the command name and arguments given when the process was created by examining the user block. Failing this, the command name is printed, as it would have appeared without the -f option, in square brackets.

The column headings and the meaning of the columns in a *ps* listing are given below; the letters f and l indicate the option (full or long, respectively) that causes the corresponding heading to appear; all means that the heading always appears. *Note:* These two options determine only what information is provided for a process; they do not determine which processes will be listed.

- F (l) Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.
- S (l) The state of the process:
 - O Process is running on a processor.
 - S Sleeping: process is waiting for an event to complete.

ps(1)

	R	Runnable: process is on run queue.
	Z	Zombie state: process terminated and parent not waiting.
	T	Process is stopped, either by a job control signal or because it is being traced.
UID (f,l)		The effective user ID number of the process (the login name is printed under the <code>-f</code> option).
PID (all)		The process ID of the process (this datum is necessary in order to kill a process).
PPID (f,l)		The process ID of the parent process.
C (f,l)		Processor utilization for scheduling (obsolete). Not printed when the <code>-c</code> option is used.
CLS (f,l)		Scheduling class. Printed only when the <code>-c</code> option is used.
PRI (l)		The priority of the process. Without the <code>-c</code> option, higher numbers mean lower priority. With the <code>-c</code> option, higher numbers mean higher priority.
NI (l)		Nice value, used in priority computation. Not printed when the <code>-c</code> option is used. Only processes in the certain scheduling classes have a nice value.
ADDR (l)		The memory address of the process.
SZ (l)		The total size of the process in virtual memory, including all mapped files and devices, in pages. See <code>pagesize(1)</code> .
WCHAN (l)		The address of an event for which the process is sleeping (if blank, the process is running).
STIME (f)		The starting time of the process, given in hours, minutes, and seconds. (A process begun more than twenty-four hours before the <code>ps</code> inquiry is executed is given in months and days.)
TTY (all)		The controlling terminal for the process (the message, <code>?</code> , is printed when there is no controlling terminal).
TIME (all)		The cumulative execution time for the process.
CMD (all)		The command name (the full command name and its arguments, up to a limit of 80 characters, are printed under the <code>-f</code> option).
The following two additional columns are printed when the <code>-j</code> option is specified:		
PGID		The process ID of the process group leader.
SID		The process ID of the session leader.
The following two additional columns are printed when the <code>-L</code> option is specified:		

LWP The lwp ID of the lwp being reported.

NLWP The number of lwps in the process (if `-f` is also specified).

Under the `-L` option, one line is printed for each lwp in the process and the time-reporting fields `STIME` and `TIME` show the values for the lwp, not the process. A traditional single-threaded process contains only one lwp.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked `<defunct>`.

`-o format` The `-o` option allows the output format to be specified under user control.

The format specification must be a list of names presented as a single argument, blank- or comma-separated. Each variable has a default header. The default header can be overridden by appending an equals sign and the new text of the header. The rest of the characters in the argument will be used as the header text. The fields specified will be written in the order specified on the command line, and should be arranged in columns in the output. The field widths will be selected by the system to be at least as wide as the header text (default or overridden value). If the header text is null, such as `-o user=`, the field width will be at least as wide as the default header text. If all header text fields are null, no header line will be written.

The following names are recognized in the POSIX locale:

<code>user</code>	The effective user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
<code>ruser</code>	The real user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
<code>group</code>	The effective group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
<code>rgroup</code>	The real group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
<code>pid</code>	The decimal value of the process ID.
<code>ppid</code>	The decimal value of the parent process ID.
<code>pgid</code>	The decimal value of the process group ID.
<code>pcpu</code>	The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of “recently” in this context is unspecified. The CPU time available is determined in an unspecified manner.
<code>vsz</code>	The total size of the process in virtual memory, in kilobytes.

ps(1)

nice	The decimal value of the system scheduling priority of the process. See <code>nice(1)</code> .
etime	In the POSIX locale, the elapsed time since the process was started, in the form: [<i>dd-</i> <i>hh:</i> <i>mm:ss</i> where <i>dd</i> is the number of days <i>hh</i> is the number of hours <i>mm</i> is the number of minutes <i>ss</i> is the number of seconds The <i>dd</i> field will be a decimal integer. The <i>hh</i> , <i>mm</i> and <i>ss</i> fields will be two-digit decimal integers padded on the left with zeros.
time	In the POSIX locale, the cumulative CPU time of the process in the form: [<i>dd-</i>] <i>hh:mm:ss</i> The <i>dd</i> , <i>hh</i> , <i>mm</i> , and <i>ss</i> fields will be as described in the <code>etime</code> specifier.
tty	The name of the controlling terminal of the process (if any) in the same format used by the <code>who(1)</code> command.
comm	The name of the command being executed (<code>argv[0]</code> value) as a string.
args	The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-dependent whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of <code>ps</code> . The Solaris implementation limits the string to 80 bytes; the string is the version of the argument list as it was passed to the command when it started.
The following names are recognized in the Solaris implementation:	
f	Flags (hexadecimal and additive) associated with the process.
s	The state of the process.
c	Processor utilization for scheduling (obsolete).

uid	The effective user ID number of the process as a decimal integer.
ru+id	The real user ID number of the process as a decimal integer.
gid	The effective group ID number of the process as a decimal integer.
rgid	The real group ID number of the process as a decimal integer.
projid	The project ID number of the process as a decimal integer.
project	The project ID of the process as a textual value if that value can be obtained; otherwise as a decimal integer.
sid	The process ID of the session leader.
taskid	The task ID of the process.
class	The scheduling class of the process.
pri	The priority of the process. Higher numbers mean higher priority.
opri	The obsolete priority of the process. Lower numbers mean higher priority.
lwp	The decimal value of the lwp ID. Requesting this formatting option causes one line to be printed for each lwp in the process.
nlwp	The number of lwps in the process.
psr	The number of the processor to which the process or lwp is bound.
pset	The ID of the processor set to which the process or lwp is bound.
addr	The memory address of the process.
osz	The total size of the process in virtual memory, in pages.
wchan	The address of an event for which the process is sleeping (if -, the process is running).
stime	The starting time or date of the process, printed with no blanks.
rss	The resident set size of the process, in kilobytes.
pmem	The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.
fname	The first 8 bytes of the base name of the process's executable file.

Only `comm` and `args` are allowed to contain blank characters; all others, including the Solaris implementation variables, are not.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

ps(1)

Format	Default	Format	Default
Specifier	Header	Specifier	Header
args	COMMAND	ppid	PPID
comm	COMMAND	rgroup	RGROUP
etime	ELAPSED	ruser	RUSER
group	GROUP	time	TIME
nice	NI	tty	TT
pcpu	%CPU	user	USER
pgid	PGID	vsz	VSZ
pid	PID		

The following table lists the Solaris implementation format specifiers and the default header used with each.

Format	Default	Format	Default
Specifier	Header	Specifier	Header
addr	ADDR	projid	PROJID
c	C	project	PROJECT
class	CLS	psr	PSR
f	F	rgid	RGID
fname	COMMAND	rss	RSS
gid	GID	ruid	RUID
lwp	LWP	s	S
nlwp	NLWP	sid	SID
opri	PRI	stime	STIME
osz	SZ	taskid	TASKID
pmem	%MEM	uid	UID
pri	PRI	wchan	WCHAN

EXAMPLES

EXAMPLE 1 An example of the ps command

The command:

```
example% ps -o user,pid,ppid=MOM -o args
```

EXAMPLE 1 An example of the ps command (Continued)

writes the following in the POSIX locale:

```
USER  PID  MOM  COMMAND
helene 34   12  ps -o uid,pid,ppid=MOM -o args
```

The contents of the COMMAND field need not be the same due to possible truncation.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of ps: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, LC_TIME, and NLSPATH.

COLUMNS Override the system-selected horizontal screen size, used to determine the number of text columns to display.

EXIT STATUS

The following exit values are returned:

0 Successful completion.
>0 An error occurred.

FILES

/dev/pts/*
/dev/term/* terminal (“tty”) names searcher files
/etc/passwd UID information supplier
/proc/* process control files
/tmp/ps_data internal data structure

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled (see USAGE)
Interface Stability	Standard

SEE ALSO

`kill(1)`, `nice(1)`, `pagesize(1)`, `pgrep(1)`, `priocntl(1)`, `who(1)`, `getty(1M)`, `proc(4)`, `ttysrch(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

NOTES

Things can change while ps is running. The snapshot it gives is true only for a split-second, and it may not be accurate by the time you see it. Some data printed for defunct processes is irrelevant.

If no options to select processes are specified, ps will report all processes associated with the controlling terminal. If there is no controlling terminal, there will be no report other than the header.

ps(1)

`ps -ef` or `ps -o stime` may not report the actual start of a tty login session, but rather an earlier time, when a `getty` was last respawned on the tty line.

`ps` is CSI-enabled except for login names (usernames).

NAME	ps – display the status of current processes
SYNOPSIS	<code>/usr/ucb/ps [-aceglnrSuUvwx] [-t <i>term</i>] [<i>num</i>]</code>
DESCRIPTION	<p>The <code>ps</code> command displays information about processes. Normally, only those processes that are running with your effective user ID and are attached to a controlling terminal (see <code>termio(7I)</code>) are shown. Additional categories of processes can be added to the display using various options. In particular, the <code>-a</code> option allows you to include processes that are not owned by you (that do not have your user ID), and the <code>-x</code> option allows you to include processes without controlling terminals. When you specify both <code>-a</code> and <code>-x</code>, you get processes owned by anyone, with or without a controlling terminal. The <code>-r</code> option restricts the list of processes printed to running and runnable processes.</p> <p><code>ps</code> displays in tabular form the process ID, under <code>PID</code>; the controlling terminal (if any), under <code>TT</code>; the cpu time used by the process so far, including both user and system time, under <code>TIME</code>; the state of the process, under <code>S</code>; and finally, an indication of the <code>COMMAND</code> that is running.</p> <p>The state is given by a single letter from the following:</p> <ul style="list-style-type: none"> O Process is running on a processor. S Sleeping. Process is waiting for an event to complete. R Runnable. Process is on run queue. Z Zombie state. Process terminated and parent not waiting. T Traced. Process stopped by a signal because parent is tracing it.
OPTIONS	<p>The following options must all be combined to form the first argument:</p> <ul style="list-style-type: none"> -a Includes information about processes owned by others. -c Displays the command name rather than the command arguments. -e Displays the environment as well as the arguments to the command. -g Displays all processes. Without this option, <code>ps</code> only prints interesting processes. Processes are deemed to be uninteresting if they are process group leaders. This normally eliminates top-level command interpreters and processes waiting for users to login on free terminals. -l Displays a long listing, with fields <code>F</code>, <code>PPID</code>, <code>CP</code>, <code>PRI</code>, <code>NI</code>, <code>SZ</code>, <code>RSS</code>, and <code>WCHAN</code> as described below. -n Produces numerical output for some fields. In a user listing, the <code>USER</code> field is replaced by a <code>UID</code> field. -r Restricts output to running and runnable processes. -S Displays accumulated CPU time used by this process and all of its reaped children.

ps(1B)

- t *term* Lists only process data associated with the terminal, *term*. Terminal identifiers may be specified in one of two forms: the device's file name (for example, `tty04` or `term/14`) or, if the device's file name starts with `tty`, just the digit identifier (for example, `04`).
- u Displays user-oriented output. This includes fields `USER`, `%CPU`, `%MEM`, `SZ`, `RSS`, and `START` as described below.
- U Obsolete. This option no longer has any effect. It causes `ps` to exit without printing the process listing.
- v Displays a version of the output containing virtual memory. This includes fields `SIZE`, `%CPU`, `%MEM`, and `RSS`, described below.
- w Uses a wide output format (132 columns rather than 80). If the option letter is repeated, that is, `-ww`, uses arbitrarily wide output. This information is used to decide how much of long commands to print.
- x Includes processes with no controlling terminal.
- num* A process number may be given, in which case the output is restricted to that process. This option must be supplied last.

DISPLAY FORMATS

Fields that are not common to all output formats:

<code>USER</code>	Name of the owner of the process.
<code>%CPU</code>	CPU use of the process. This is a decaying average over up to a minute of previous (real) time.
<code>NI</code>	Process scheduling increment (see <code>getpriority(3C)</code> and <code>nice(3UCB)</code>).
<code>SIZE</code>	The total size of the process in virtual memory, including all mapped files and devices, in kilobyte units.
<code>SZ</code>	Same as <code>SIZE</code> .
<code>RSS</code>	Real memory (resident set) size of the process, in kilobyte units.
<code>UID</code>	Numerical user-ID of process owner.
<code>PPID</code>	Numerical ID of parent of process.
<code>CP</code>	Short-term CPU utilization factor (used in scheduling).
<code>PRI</code>	The priority of the process (higher numbers mean lower priority).
<code>START</code>	The starting time of the process, given in hours, minutes, and seconds. A process begun more than 24 hours before the <code>ps</code> inquiry is executed is given in months and days.
<code>WCHAN</code>	The address of an event for which the process is sleeping (if blank, the process is running).

%MEM The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.

F Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked `<defunct>`; otherwise, `ps` tries to determine the command name and arguments given when the process was created by examining the user block.

FILES /dev/tty*

/etc/passwd UID information supplier

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO `kill(1)`, `ps(1)`, `whodo(1M)`, `getpriority(3C)`, `nice(3UCB)`, `proc(4)`, `attributes(5)`, `termio(7I)`

NOTES Things can change while `ps` is running. The picture `ps` gives is only a close approximation to the current state. Some data printed for defunct processes is irrelevant.

pvs(1)

NAME	pvs – display the internal version information of dynamic objects
SYNOPSIS	pvs [-Cdlnorsv] [-N <i>name</i>] <i>file</i> ...
DESCRIPTION	<p>The <code>pvs</code> utility displays any internal version information contained within an ELF file. Commonly, these files are dynamic executables and shared objects, and possibly relocatable objects. This version information can fall into one of two categories:</p> <ul style="list-style-type: none">■ version definitions■ version dependencies <p>Version <i>definitions</i> describe the interfaces made available by an ELF file. Each version definition is associated to a set of global symbols provided by the file. Version definitions may be assigned to a file during its creation by the link-editor using the <code>-M</code> option and the associated <i>mapfile</i> directives (see the <i>Linker and Libraries Guide</i> for more details).</p> <p>Version <i>dependencies</i> describe the binding requirements of dynamic objects on the version definitions of any shared object dependencies. When a dynamic object is built with a shared object, the link-editor records information within the dynamic object indicating that the shared object is a dependency. This dependency must be satisfied at runtime. If the shared object also contains version <i>definitions</i>, then those version definitions that satisfy the global symbol requirements of the dynamic object will also be recorded in the dynamic object being created. At process initialization, the runtime linker will use any version <i>dependencies</i> as a means of validating the interface requirements of the dynamic objects used to construct the process.</p>
OPTIONS	<p>The following options are supported. If neither the <code>-d</code> or <code>-r</code> options are specified, both will be enabled.</p> <ul style="list-style-type: none"><code>-C</code> Demangles C++ symbol names.<code>-d</code> Prints version definition information.<code>-l</code> When used with the <code>-s</code> option, prints any symbols that have been reduced from global to local binding due to versioning. By convention, these symbol entries are located in the <i>.symtab</i> section, and fall between the <i>FILE</i> symbol representing the output file, and the <i>FILE</i> symbol representing the first input file used to generate the output file. These reduced symbol entries are assigned the fabricated version definition <code>_REDUCED_</code>. No reduced symbols will be printed if the file has been stripped (see <code>strip(1)</code>), or if the symbol entry convention cannot be determined.<code>-n</code> Normalizes version definition information. By default, all version definitions within the object are displayed. However, version definitions may inherit other version definitions, and under normalization only the head of each inheritance list is displayed.<code>-N name</code> Prints only the information for the given version definition <i>name</i> and any of its inherited version definitions (when used with the <code>-d</code> option), or for the given dependency file <i>name</i> (when used with the <code>-r</code> option).

- o Creates one-line version definition output. By default, file, version definitions, and any symbol output is indented to ease human inspection. This option prefixes each output line with the file and version definition name and may be more useful for analysis with automated tools.
- r Prints version dependency (requirements) information.
- s Prints the symbols associated with each version definition. Any data symbols are accompanied with the size, in bytes, of the data item.
- v Verbose output. Indicates any weak version definitions, and any version definition inheritance. When used with the `-N` and `-d` options, the inheritance of the base version definition is also shown. When used with the `-s` option, the version symbol definition is also shown.

OPERANDS The following operands are supported.

file The ELF file about which internal version information is displayed.

EXAMPLES **EXAMPLE 1** Displaying version definitions

The following example displays the version definitions of `libelf.so.1`:

```
% pvs -d /usr/lib/libelf.so.1
libelf.so.1;
SUNW_1.1
```

EXAMPLE 2 Creating a one-liner display

A normalized, one-liner display, suitable for creating a *mapfile* version control directive, can be created using the `-n` and `-o` options:

```
% pvs -don /usr/lib/libelf.so.1
/usr/lib/libelf.so.1 - SUNW_1.1;
```

EXAMPLE 3 Displaying version requirements

The following example displays the version requirements of `ldd` and `pvs`:

```
% pvs -r /usr/bin/ldd /usr/bin/pvs
/usr/bin/ldd:
libelf.so.1 (SUNW_1.1);
libc.so.1 (SUNW_1.1);
/usr/bin/pvs:
libelf.so.1 (SUNW_1.1);
libc.so.1 (SUNW_1.1);
```

EXIT STATUS If the requested version information is not found, a non-zero value is returned; otherwise a 0 value is returned.

Version information is determined not found when any of the following is true:

- the `-d` option is specified and no version definitions are found;

pvs(1)

- the `-r` option is specified and no version requirements are found;
- neither the `-d` nor `-r` option is specified and no version definitions or version requirements are found.

SEE ALSO	<code>cd(1)</code> , <code>ksh(1)</code> , <code>sh(1)</code> , <code>shell_builtins(1)</code> , <code>attributes(5)</code> , <code>environ(5)</code> , <code>standards(5)</code>								
DIAGNOSTICS	“Cannot open . .” and “Read error in . .” indicate possible file system trouble and should be referred to a UNIX system administrator.								
NOTES	If you move the current directory or one above it, <code>pwd</code> may not give the correct response. Use the <code>cd(1)</code> command with a full path name to correct this situation.								

ranlib(1)

NAME ranlib – convert archives to random libraries

SYNOPSIS `/usr/ccs/bin/ranlib archive`

DESCRIPTION The `ranlib` utility was used in SunOS 4.x to add a table of contents to archive libraries, which converted each archive to a form that could be linked more rapidly. This is no longer needed, as the `ar(1)` command automatically provides all the functionality `ranlib` used to provide.

This script is provided as a convenience for software developers who need to maintain Makefiles that are portable across a variety of operating systems.

EXIT STATUS `ranlib` has exit status 0.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

SEE ALSO `ar(1)`, `ar(3HEAD)`, `attributes(5)`

NAME	rcp – remote file copy
SYNOPSIS	<pre>rcp [-p] filename1 filename2 rcp [-pr] filename... directory</pre>
DESCRIPTION	<p>The <code>rcp</code> command copies files between machines. Each <i>filename</i> or <i>directory</i> argument is either a remote file name of the form:</p> <pre>hostname:path</pre> <p>or a local file name (containing no ":" (colon) characters, or "/" (backslash) before any ":" (colon) characters).</p> <p>The <i>hostname</i> can be an IPv4 or IPv6 address string. See <code>inet(7P)</code> and <code>inet6(7P)</code>. Since IPv6 addresses already contain colons, the <i>hostname</i> should be enclosed in a pair of square brackets when an IPv6 address is used. Otherwise, the first occurrence of a colon can be interpreted as the separator between <i>hostname</i> and <i>path</i>. For example,</p> <pre>[1080::8:800:200C:417A]:tmp/file</pre> <p>If a <i>filename</i> is not a full path name, it is interpreted relative to your home directory on <i>hostname</i>. A <i>path</i> on a remote host may be quoted using <code>\</code>, <code>"</code>, or <code>'</code>, so that the metacharacters are interpreted remotely.</p> <p><code>rcp</code> does not prompt for passwords; your current local user name must exist on <i>hostname</i> and allow remote command execution by <code>rsh(1)</code>.</p> <p><code>rcp</code> handles third party copies, where neither source nor target files are on the current machine. Hostnames may also take the form</p> <pre>username@hostname:filename</pre> <p>to use <i>username</i> rather than your current local user name as the user name on the remote host. <code>rcp</code> also supports Internet domain addressing of the remote host, so that:</p> <pre>username@host.domain:filename</pre> <p>specifies the username to be used, the hostname, and the domain in which that host resides. File names that are not full path names will be interpreted relative to the home directory of the user named <i>username</i>, on the remote host.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -p Attempts to give each copy the same modification times, access times, modes, and ACLs if applicable as the original file. -r Copies each subtree rooted at <i>filename</i>; in this case the destination must be a directory.
USAGE	<p>See <code>largefile(5)</code> for the description of the behavior of <code>rcp</code> when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).</p> <p>The <code>rcp</code> command is IPv6-enabled. See <code>ip6(7P)</code>.</p>

rcp(1)

EXIT STATUS 0 All files were copied successfully.
>0 An error occurred.

FILES \$HOME/.profile

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc
CSI	Enabled

SEE ALSO `cpio(1)`, `ftp(1)`, `rlogin(1)`, `rsh(1)`, `setfacl(1)`, `tar(1)`, `hosts.equiv(4)`, `attributes(5)`, `largefile(5)`, `inet(7P)`, `inet6(7P)`, `ip6(7P)`

NOTES `rcp` is meant to copy between different hosts. Attempting to `rcp` a file onto itself, as with:

```
example% rcp tmp/file myhost:/tmp/file
```

results in a severely corrupted file.

`rcp` may not correctly fail when the target of a copy is a file instead of a directory.

`rcp` can become confused by output generated by commands in a `$HOME/.profile` on the remote host.

`rcp` requires that the source host have permission to execute commands on the remote host when doing third-party copies.

`rcp` does not properly handle symbolic links. Use `tar` or `cpio` piped to `rsh` to obtain remote copies of directories containing symbolic links or named pipes. See `tar(1)` and `cpio(1)`.

If you forget to quote metacharacters intended for the remote host, you will get an incomprehensible error message.

`rcp` will fail if you copy ACLs to a file system that does not support ACLs.

`rcp` is CSI-enabled except for the handling of username, hostname, and domain.

NAME	rdist – remote file distribution program
SYNOPSIS	<pre>rdist [-b] [-D] [-h] [-i] [-n] [-q] [-R] [-v] [-w] [-y] [-d <i>macro</i> = <i>value</i>] [-f <i>distfile</i>] [-m <i>host</i>]... rdist [-b] [-D] [-h] [-i] [-n] [-q] [-R] [-v] [-w] [-y] -c <i>pathname</i>... [<i>login</i> @] <i>hostname</i> [: <i>destpath</i>]</pre>
DESCRIPTION	<p>The <code>rdist</code> utility maintains copies of files on multiple hosts. It preserves the owner, group, mode, and modification time of the master copies, and can update programs that are executing. (Note: <code>rdist</code> does not propagate ownership or mode changes when the file contents have not changed.) Normally, a copy on a remote host is updated if its size or modification time differs from the original on the local host. (With the <code>-y</code> option (younger mode), only the modification times are checked, not the size. See OPTIONS below.)</p> <p>There are two forms of the <code>rdist</code> command. In the first form shown in the SYNOPSIS section above, <code>rdist</code> reads the indicated <i>distfile</i> for instructions on updating files and/or directories. If <i>distfile</i> is <code>'-'</code>, the standard input is used. If no <code>-f</code> option is present, <code>rdist</code> first looks in its working directory for <i>distfile</i>, and then for <code>Distfile</code>, for instructions.</p> <p>The second form shown in SYNOPSIS uses the <code>-c</code> option and specifies paths as command line options.</p> <p>In order to be able to use <code>rdist</code> across machines, each host machine must have a <code>/etc/host.equiv</code> file, or the user must have an entry in the <code>.rhosts</code> file in the home directory. See <code>hosts.equiv(4)</code> for more information.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -b Binary comparison. Performs a binary comparison and updates files if they differ, rather than merely comparing dates and sizes. -c <i>pathname</i> . . . [<i>login</i> @]<i>hostname</i>[: <i>destpath</i>] Copies each <i>pathname</i> to the named host; if <i>destpath</i> is specified, it will not update any <i>pathname</i> on the named host. (Relative filenames are taken as relative to your home directory.) If the <code>'login @'</code> prefix is given, the update is performed with the user ID of <i>login</i>. If the <code>':destpath'</code> is given, the remote file is installed as that <i>pathname</i>. -d <i>macro=value</i> Defines <i>macro</i> to have <i>value</i>. This option is used to define or override macro definitions in the <i>distfile</i>. <i>value</i> can be the empty string, one name, or a list of names surrounded by parentheses and separated by white space. -D Enables debugging.

rdist(1)

	<p>-f <i>distfile</i> Uses the description file <i>distfile</i>. A '-' as the <i>distfile</i> argument denotes the standard input.</p> <p>-h Follows symbolic links. Copies the file that the link points to rather than the link itself.</p> <p>-i Ignores unresolved links. <i>rdist</i> will normally try to maintain the link structure of files being transferred and warn the user if all the links cannot be found.</p> <p>-m <i>host</i> Limits which machines are to be updated. Multiple -m arguments can be given to limit updates to a subset of the hosts listed in the <i>distfile</i>.</p> <p>-n Prints the commands without executing them. This option is useful for debugging a <i>distfile</i>.</p> <p>-q Quiet mode. Does not display the files being updated on the standard output.</p> <p>-R Removes extraneous files. If a directory is being updated, removes files on the remote host that do not correspond to those in the master (local) directory. This is useful for maintaining truly identical copies of directories.</p> <p>-v Verifies that the files are up to date on all the hosts. Any files that are out of date are displayed, but no files are updated, nor is any mail sent.</p> <p>-w Whole mode. The whole file name is appended to the destination directory name. Normally, only the last component of a name is used when renaming files. This preserves the directory structure of the files being copied, instead of flattening the directory structure. For instance, renaming a list of files such as <i>dir1/dir2</i> to <i>dir3/dir2</i> would create files <i>dir3/dir1</i> and <i>dir3/dir2</i> instead of <i>dir3</i> and <i>dir3</i>. When the -w option is used with a filename that begins with <i>~</i>, everything except the home directory is appended to the destination name.</p> <p>-y Younger mode. Does not update remote copies that are younger than the master copy, but issues a warning message instead. Only modification times are checked. No comparison of size is made.</p>
White Space Characters	NEWLINE, TAB, and SPACE characters are all treated as white space; a mapping continues across input lines until the start of the next mapping: either a single <i>filename</i> followed by a '->' or the opening parenthesis of a filename list.
Comments	Comments begin with # and end with a NEWLINE.

Distfiles	<p>The distfile contains a sequence of entries that specify the files to be copied, the destination files to be copied, the destination hosts, and what operations to perform to do the updating. Each entry has one of the following formats:</p> <pre>variable_name '=' name_list [label:] source_list '->' destination_list command_list [label:] source_list '::' time_stamp_file command_list</pre> <p>The first format is used for defining variables. The second format is used for distributing files to other hosts. The third format is used for making lists of files that have been changed since some given date. The source list specifies a list of files and/or directories on the local host that are to be used as the master copy for distribution. The destination list is the list of hosts to which these files are to be copied. Each file in the source list is added to a list of changes if the file is out of date on the host that is being updated (second format) or if the file is newer than the time stamp file (third format). Labels are optional. They are used to identify a command for partial updates. The colon (:) is used after an optional label, while the double colon (::) is used for making lists of files that have been changed since a certain date (specified by the date/time of the <i>time_stamp</i> file). Typically, only <code>notify</code> is used with the '::' format of the command line.</p>
Macros	<p><code>rdist</code> has a limited macro facility. Macros are only expanded in filename or hostname lists, and in the argument lists of certain primitives. Macros cannot be used to stand for primitives or their options, or the '->' or '::' symbols.</p> <p>A macro definition is a line of the form:</p> <pre>macro = value</pre> <p>A macro reference is a string of the form:</p> <pre>`\${macro}</pre> <p>although (as with <code>make(1S)</code>) the braces can be omitted if the macro name consists of just one character.</p>
Metacharacters	<p>The shell meta-characters: <code>[]</code>, <code>{ }</code>, <code>*</code> and <code>?</code> are recognized and expanded (on the local host only) just as they are with <code>csh(1)</code>. Metacharacters can be escaped by prepending a backslash.</p> <p>The <code>~</code> character is also expanded in the same way as with <code>csh</code>; however, it is expanded separately on the local and destination hosts.</p>
Filenames	<p>File names that do not begin with <code>' / '</code> or <code>' ~ '</code> are taken to be relative to user's home directory on each destination host; they are <i>not</i> relative to the current working directory. Multiple file names must be enclosed within parentheses.</p>
Primitives	<p>The following primitives can be used to specify actions <code>rdist</code> is to take when updating remote copies of each file.</p>

rdist(1)

`install [-b] [-h] [-i] [-R] [-v] [-w] [-y] [newname]`

Copy out of date files and directories (recursively). If no *newname* operand is given, the name of the local file is given to the remote host's copy. If absent from the remote host, parent directories in a filename's path are created. To help prevent disasters, a non-empty directory on a target host is not replaced with a regular file or a symbolic link by `rdist`. However, when using the `-R` option, a non-empty directory is removed if the corresponding filename is completely absent on the master host.

The options for `install` have the same semantics as their command line counterparts, but are limited in scope to a particular map. The login name used on the destination host is the same as the local host unless the destination name is of the format *login@host*. In that case, the update is performed under the username *login*.

`notify address ...`

Send mail to the indicated email *address* of the form:

user@host

that lists the files updated and any errors that may have occurred. If an address does not contain a '@host' suffix, `rdist` uses the name of the destination host to complete the address.

`except filename ...`

Omit from updates the files named as arguments.

`except_pat pattern ...`

Omit from updates the filenames that match each regular-expression *pattern* (see `ed(1)` for more information on regular expressions). Note that '\ ' and '\\$' characters must be escaped in the distfile. Shell variables can also be used within a pattern, however shell filename expansion is not supported.

`special [filename] ... "command-line "`

Specify a Bourne shell, `sh(1)` command line to execute on the remote host after each named file is updated. If no *filename* argument is present, the *command-line* is performed for every updated file, with the shell variable `FILE` set to the file's name on the local host. The quotation marks allow *command-line* to span input lines in the distfile; multiple shell commands must be separated by semicolons (;).

The default working directory for the shell executing each *command-line* is the user's home directory on the remote host.

IPv6 The `rdist` command is IPv6-enabled. See `ip6(7P)`.

EXAMPLES

EXAMPLE 1 A sample distfile

The following sample distfile instructs `rdist` to maintain identical copies of a shared library, a shared-library initialized data file, several include files, and a directory, on hosts named `hermes` and `magus`. On `magus`, commands are executed as `super-user`.

EXAMPLE 1 A sample distfile *(Continued)*

rdist notifies merlin@druid whenever it discovers that a local file has changed relative to a timestamp file. (Parentheses are used when the source or destination list contains zero or more names separated by white-space.)

```
HOSTS = ( hermes root@magus )

FILES = ( /usr/local/lib/libcant.so.1.1
          /usrlocal/lib/libcant.sa.1.1 /usr/local/include/{*.h}
          /usr/local/bin )

(${FILES}) -> (${HOSTS})
          install -R ;
${FILES} :: /usr/local/lib/timestamp
          notify merlin@druid ;
```

FILES ~/.rhosts user's trusted hosts and users
 /etc/host.equiv system trusted hosts and users
 /tmp/rdist* temporary file for update lists

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc

SEE ALSO csh(1), ed(1), make(1S), sh(1), stat(2), hosts.equiv(4), attributes(5), ip6(7P)

DIAGNOSTICS A complaint about mismatch of rdist version numbers may really stem from some problem with starting your shell, for example, you are in too many groups.

WARNINGS The super-user does not have its accustomed access privileges on NFS mounted file systems. Using rdist to copy to such a file system may fail, or the copies may be owned by user "nobody".

BUGS Source files must reside or be mounted on the local host.

There is no easy way to have a special command executed only once after all files in a directory have been updated.

Variable expansion only works for name lists; there should be a general macro facility.

rdist aborts on files that have a negative modification time (before Jan 1, 1970).

There should be a "force" option to allow replacement of non-empty directories by regular files or symlinks. A means of updating file modes and owners of otherwise identical files is also needed.

read(1)

NAME	read – read a line from standard input
SYNOPSIS	<code>/usr/bin/read [-r] var...</code>
sh	<code>read name...</code>
csch	<code>set variable = \$<</code>
ksh	<code>read [-prsu [n]] [name ? prompt] [name...]</code>
/usr/bin/read	<p>The read utility will read a single line from standard input.</p> <p>By default, unless the <code>-r</code> option is specified, backslash (<code>\</code>) acts as an escape character. If standard input is a terminal device and the invoking shell is interactive, read will prompt for a continuation line when:</p> <ul style="list-style-type: none">■ The shell reads an input line ending with a backslash, unless the <code>-r</code> option is specified.■ A here-document is not terminated after a <code>NEWLINE</code> character is entered. <p>The line will be split into fields as in the shell. The first field will be assigned to the first variable <code>var</code>, the second field to the second variable <code>var</code>, and so forth. If there are fewer <code>var</code> operands specified than there are fields, the leftover fields and their intervening separators will be assigned to the last <code>var</code>. If there are fewer fields than <code>vars</code>, the remaining <code>vars</code> will be set to empty strings.</p> <p>The setting of variables specified by the <code>var</code> operands will affect the current shell execution environment. If it is called in a subshell or separate utility execution environment, such as one of the following:</p> <pre>(read foo) nohup read ... find . -exec read ... \;</pre> <p>it will not affect the shell variables in the caller's environment.</p> <p>The standard input must be a text file.</p> <p>sh One line is read from the standard input and, using the internal field separator, <code>IFS</code> (normally space or tab), to delimit word boundaries, the first word is assigned to the first <code>name</code>, the second word to the second <code>name</code>, and so on, with leftover words assigned to the last <code>name</code>. Lines can be continued using <code>\newl ine</code>. Characters other than <code>NEWLINE</code> can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to <code>names</code>, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an end-of-file is encountered.</p> <p>csch The notation:</p> <pre>set variable = \$<</pre> <p>loads one line of standard input as the value for <code>variable</code>. (See <code>csch(1)</code>).</p>

ksh	The shell input mechanism. One line is read and is broken up into fields using the characters in IFS as separators. The escape character, (\), is used to remove any special meaning for the next character and for line continuation. In raw mode, -r, the \ character is not treated specially. The first field is assigned to the first <i>name</i> , the second field to the second <i>name</i> , and so on, with leftover fields assigned to the last <i>name</i> . The -p option causes the input line to be taken from the input pipe of a process spawned by the shell using &. If the -s flag is present, the input will be saved as a command in the history file. The flag -u can be used to specify a one digit file descriptor unit <i>n</i> to read from. The file descriptor can be opened with the <code>exec</code> special command. The default value of <i>n</i> is 0. If <i>name</i> is omitted, REPLY is used as the default <i>name</i> . The exit status is 0 unless the input file is not open for reading or an end-of-file is encountered. An end-of-file with the -p option causes cleanup for this process so that another can be spawned. If the first argument contains a ?, the remainder of this word is used as a <i>prompt</i> on standard error when the shell is interactive. The exit status is 0 unless an end-of-file is encountered.
OPTIONS	The following option is supported: -r Does not treat a backslash character in any special way. Considers each backslash to be part of the input line.
OPERANDS	The following operand is supported: <i>var</i> The name of an existing or non-existing shell variable.
EXAMPLES	EXAMPLE 1 An example of the read command The following example for /usr/bin/read prints a file with the first field of each line moved to the end of the line: <pre>example% while read -r xx yy do printf "%s %s\n" "\$yy" "\$xx" done < input_file</pre>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>read</code> : LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH. IFS Determines the internal field separators used to delimit fields. PS2 Provides the prompt string that an interactive shell will write to standard error when a line ending with a backslash is read and the -r option was not specified, or if a here-document is not terminated after a newline character is entered.
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 End-of-file was detected or an error occurred.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	readfile, longline – reads file, gets longest line				
SYNOPSIS	readfile <i>filename</i> longline [<i>filename</i>]				
DESCRIPTION	<p>The <code>readfile</code> function reads <i>filename</i> and copies it to <i>stdout</i>. No translation of NEWLINE is done. It keeps track of the longest line it reads and if there is a subsequent call to <code>longline</code>, the length of that line, including the NEWLINE character, is returned.</p> <p>The <code>longline</code> function returns the length, including the NEWLINE character, of the longest line in <i>filename</i>. If <i>filename</i> is not specified, it uses the file named in the last call to <code>readfile</code>.</p>				
EXAMPLES	<p>EXAMPLE 1 Typical use of <code>readfile</code> and <code>longline</code></p> <p>Here is a typical use of <code>readfile</code> and <code>longline</code> in a text frame definition file:</p> <pre> . . . text=`readfile myfile` columns=`longline` . . . </pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>cat(1)</code> , <code>attributes(5)</code>				
DIAGNOSTICS	<p>If <i>filename</i> does not exist, <code>readfile</code> will return <code>FALSE</code> (that is, the expression will have an error return).</p> <p><code>longline</code> returns 0 if a <code>readfile</code> has not previously been issued.</p>				
NOTES	More than one descriptor can call <code>readfile</code> in the same frame definition file. In text frames, if one of those calls is made from the <code>text</code> descriptor, then a subsequent use of <code>longline</code> will always get the longest line of the file read by the <code>readfile</code> associated with the <code>text</code> descriptor, even if it was not the most recent use of <code>readfile</code> .				

readonly(1)

NAME	readonly – shell built-in function to protect the value of the given variable from reassignment				
sh	readonly [<i>name</i> ...]				
ksh	**readonly [<i>name</i> [= <i>value</i>] ...]				
sh	The given <i>names</i> are marked <code>readonly</code> and the values of the these <i>names</i> may not be changed by subsequent assignment. If no arguments are given, a list of all <code>readonly</code> names is printed.				
ksh	The given <i>names</i> are marked <code>readonly</code> and these names cannot be changed by subsequent assignment.				
	On this man page, <code>ksh(1)</code> commands that are preceded by one or two <code>**</code> (asterisks) are treated specially in the following ways:				
	<ol style="list-style-type: none">1. Variable assignment lists preceding the command remain in effect when the command completes.2. I/O redirections are processed after variable assignments.3. Errors cause a script that contains them to abort.4. Words, following a command preceded by <code>**</code> that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>ksh(1)</code> , <code>sh(1)</code> , <code>typeset(1)</code> , <code>attributes(5)</code>				

NAME	refer – expand and insert references from a bibliographic database
SYNOPSIS	refer [-ben] [-ar] [-cstring] [-kx] [-lm,n] [-p filename] [-skeys] filename...
DESCRIPTION	<p>refer is a preprocessor for nroff(1), or troff(1), that finds and formats references. The input files (standard input by default) are copied to the standard output, except for lines between ‘. [’ and ‘.]’ command lines. Such lines are assumed to contain keywords as for lookbib(1), and are replaced by information from a bibliographic data base. The user can avoid the search, override fields from it, or add new fields. The reference data, from whatever source, is assigned to a set of troff strings. Macro packages such as ms(5) print the finished reference text from these strings. A flag is placed in the text at the point of reference. By default, the references are indicated by numbers.</p> <p>When refer is used with eqn(1), neqn, or tbl(1), refer should be used first in the sequence, to minimize the volume of data passed through pipes.</p>
OPTIONS	<p>-b Bare mode — do not put any flags in text (neither numbers or labels).</p> <p>-e Accumulate references instead of leaving the references where encountered, until a sequence of the form:</p> <pre style="margin-left: 40px;">. [\$LIST\$.]</pre> <p>is encountered, and then write out all references collected so far. Collapse references to the same source.</p> <p>-n Do not search the default file.</p> <p>-ar Reverse the first <i>r</i> author names (Jones, J. A. instead of J. A. Jones). If <i>r</i> is omitted, all author names are reversed.</p> <p>-cstring Capitalize (with SMALL CAPS) the fields whose key-letters are in <i>string</i>.</p> <p>-kx Instead of numbering references, use labels as specified in a reference data line beginning with the characters %<i>x</i>; By default, <i>x</i> is L.</p> <p>-lm,n Instead of numbering references, use labels from the senior author’s last name and the year of publication. Only the first <i>m</i> letters of the last name and the last <i>n</i> digits of the date are used. If either of <i>m</i> or <i>n</i> is omitted, the entire name or date, respectively, is used.</p> <p>-p filename Take the next argument as a file of references to be searched. The default file is searched last.</p>

refer(1)

-skeys Sort references by fields whose key-letters are in the *keys* string, and permute reference numbers in the text accordingly. Using this option implies the *-e* option. The key-letters in *keys* may be followed by a number indicating how many such fields are used, with a + sign taken as a very large number. The default is AD, which sorts on the senior author and date. To sort on all authors and then the date, for instance, use the options '*-sA+T*'.

FILES /usr/lib/refer directory of programs
/usr/lib/refer/papers directory of default publication lists and indexes

NAME	regcmp – regular expression compile
SYNOPSIS	regcmp [-] <i>filename</i> ...
DESCRIPTION	The regcmp command performs a function similar to regcmp and, in most cases, precludes the need for calling regcmp from C programs. Bypassing regcmp saves on both execution time and program size. The command regcmp compiles the regular expressions in <i>filename</i> and places the output in <i>filename.i</i> .
OPTIONS	– If the – option is used, the output is placed in <i>filename.c</i> . The format of entries in <i>filename</i> is a name (C variable) followed by one or more blanks followed by one or more regular expressions enclosed in double quotes. The output of regcmp is C source code. Compiled regular expressions are represented as <code>extern char vectors</code> . <i>filename.i</i> files may thus be <code>#included</code> in C programs, or <i>filename.c</i> files may be compiled and later loaded. In the C program that uses the regcmp output, <code>regex(abc, line)</code> applies the regular expression named <code>abc</code> to <code>line</code> . Diagnostics are self-explanatory.
EXAMPLES	<p>EXAMPLE 1 Examples of the regcmp command.</p> <pre>name " ([A-Za-z] [A-Za-z0-9_]*) \$0 "</pre> <pre>telno " \({0,1} ([2-9] [01] [1-9]) \$0\) {0,1} * "</pre> <pre> " ([2-9] [0-9] {2}) \$1 [-] {0,1} "</pre> <pre> " ([0-9] {4}) \$2 "</pre>
	The three arguments to <code>telno</code> shown above must all be entered on one line.
	In the C program that uses the regcmp output,
	<pre>regex(telno, line, area, exch, rest)</pre> applies the regular expression named <code>telno</code> to <code>line</code> .
ENVIRONMENT VARIABLES	A general description of the usage of the <code>LC_*</code> environmental variables can be found in <code>environ(5)</code> .
	LC_CTYPE Determines how regcmp handles characters. When <code>LC_CTYPE</code> is set to a valid value, regcmp can display and handle text and filenames containing valid characters for that locale.
	LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	regex – match patterns against a string
SYNOPSIS	regex [-e] [-v "string"] [pattern template] ... pattern [template]
DESCRIPTION	<p>The <code>regex</code> command takes a string from the standard input, and a list of <i>pattern</i> / <i>template</i> pairs, and runs <code>regex()</code> to compare the string against each <i>pattern</i> until there is a match. When a match occurs, <code>regex</code> writes the corresponding <i>template</i> to the standard output and returns TRUE. The last (or only) <i>pattern</i> does not need a template. If that is the pattern that matches the string, the function simply returns TRUE. If no match is found, <code>regex</code> returns FALSE.</p> <p>The argument <i>pattern</i> is a regular expression of the form described in <code>regex()</code>. In most cases, <i>pattern</i> should be enclosed in single quotes to turn off special meanings of characters. Note that only the final <i>pattern</i> in the list may lack a <i>template</i>.</p> <p>The argument <i>template</i> may contain the strings <code>\$m0</code> through <code>\$m9</code>, which will be expanded to the part of <i>pattern</i> enclosed in <code>(. . .)\$0</code> through <code>(. . .)\$9</code> constructs (see examples below). Note that if you use this feature, you must be sure to enclose <i>template</i> in single quotes so that FMLI does not expand <code>\$m0</code> through <code>\$m9</code> at parse time. This feature gives <code>regex</code> much of the power of <code>cut(1)</code>, <code>paste(1)</code>, and <code>grep(1)</code>, and some of the capabilities of <code>sed(1)</code>. If there is no <i>template</i>, the default is <code>\$m0\$m1\$m2\$m3\$m4\$m5\$m6\$m7\$m8\$m9</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -e Evaluates the corresponding template and writes the result to the standard output. -v "string" Uses <i>string</i> instead of the standard input to match against patterns.
EXAMPLES	<p>EXAMPLE 1 Cutting letters out of a string</p> <p>To cut the 4th through 8th letters out of a string (this example will output <code>strin</code> and return TRUE):</p> <pre>'regex -v "my string is nice" '^.{3}(.{5})\$0' '\$m0'</pre> <p>EXAMPLE 2 Validating input in a form</p> <p>In a form, to validate input to field 5 as an integer:</p> <pre>valid='regex -v "\$F5" '^ [0-9]+\$'</pre> <p>EXAMPLE 3 Translating an environment variable in a form</p> <p>In a form, to translate an environment variable which contains one of the numbers 1, 2, 3, 4, 5 to the letters a, b, c, d, e:</p> <pre>value='regex -v "\$VAR1" 1 a 2 b 3 c 4 d 5 e '.*' 'Error'</pre> <p>Note the use of the pattern <code>' .* '</code> to mean "anything else".</p>

regex(1F)

EXAMPLE 4 Using backquoted expressions

In the example below, all three lines constitute a single backquoted expression. This expression, by itself, could be put in a menu definition file. Since backquoted expressions are expanded as they are parsed, and output from a backquoted expression (the `cat` command, in this example) becomes part of the definition file being parsed, this expression would read `/etc/passwd` and make a dynamic menu of all the login ids on the system.

```
`cat /etc/passwd | regex '^([:]*)$0.*$' `
name=$m0
action='message "$m0 is a user"''`
```

DIAGNOSTICS

If none of the patterns match, `regex` returns `FALSE`, otherwise `TRUE`.

NOTES

Patterns and templates must often be enclosed in single quotes to turn off the special meanings of characters. Especially if you use the `$m0` through `$m9` variables in the template, since `FMLI` will expand the variables (usually to `""`) before `regex` even sees them.

Single characters in character classes (inside `[]`) must be listed before character ranges, otherwise they will not be recognized. For example, `[a-zA-Z_/_]` will not find underscores (`_`) or slashes (`/`), but `[_/_a-zA-Z]` will.

The regular expressions accepted by `regcmp` differ slightly from other utilities (that is, `sed`, `grep`, `awk`, `ed`, and so forth).

`regex` with the `-e` option forces subsequent commands to be ignored. In other words, if a backquoted statement appears as follows:

```
`regex -e ...; command1; command2`
```

`command1` and `command2` would never be executed. However, dividing the expression into two:

```
`regex -e ...`command1; command2`
```

would yield the desired result.

NAME	reinit – runs an initialization file				
SYNOPSIS	reinit <i>filename</i>				
DESCRIPTION	<p>The <code>reinit</code> command is used to change the values of descriptors defined in the initialization file that was named when <code>fml</code> was invoked and/or define additional descriptors. FMLI will parse and evaluate the descriptors in <i>filename</i>, and then continue running the current application. The argument <i>filename</i> must be the name of a valid FMLI initialization file.</p> <p>The <code>reinit</code> command does not re-display the introductory frame or change the layout of screen labels for function keys.</p>

renice(1)

NAME	renice – alter priority of running processes
SYNOPSIS	renice [-n <i>increment</i>] [-i <i>idtype</i>] <i>ID</i> ... renice [-n <i>increment</i>] [-g -p -u] <i>ID</i> ... renice <i>priority</i> [-p] <i>pid</i> ... [-g <i>gid</i> ...] [-p <i>pid</i> ...] [-u <i>user</i> ...] renice <i>priority</i> -g <i>gid</i> ... [-g <i>gid</i> ...] [-p <i>pid</i> ...] [-u <i>user</i> ...] renice <i>priority</i> -u <i>user</i> ... [-g <i>gid</i> ...] [-p <i>pid</i> ...] [-u <i>user</i> ...]
DESCRIPTION	The renice command alters the scheduling priority of one or more running processes. By default, the processes to be affected are specified by their process IDs. If the first operand is a number within the valid range of priorities (-20 to 20), renice will treat it as a <i>priority</i> (as in all but the first synopsis form). Otherwise, renice will treat it as an <i>ID</i> (as in the first synopsis form).
Altering Process Priority	Users other than the privileged user may only alter the priority of processes they own, and can only monotonically increase their “nice value” within the range 0 to 19. This prevents overriding administrative fiats. The privileged user may alter the priority of any process and set the priority to any value in the range -20 to 19. Useful priorities are: 19 (the affected processes will run only when nothing else in the system wants to); 0 (the “base” scheduling priority); and any negative value (to make things go very fast). 20 is an acceptable nice value, but will be rounded down to 19.
OPTIONS	renice supports the following option features: <ul style="list-style-type: none">■ The first operand, <i>priority</i>, must precede the options and can have the appearance of a multi-digit option.■ The -g, -p, and -u options can each take multiple option-arguments.■ The <i>pid</i> option-argument can be used without its -p option.■ The -i option can be used to specify the <i>ID</i> type for the ID list. This is preferred in specifying <i>ID</i> type over the use of the -g -p -u syntax, which is now obsolete. See NOTES. The following options are supported: -g Interprets all operands or just the <i>gid</i> arguments as unsigned decimal integer process group IDs. -i This option, together with the <i>ID</i> list arguments, specifies a class of processes to which the renice command is to apply. The interpretation of the ID list depends on the value of <i>idtype</i> . The valid <i>idtype</i> arguments are: <i>pid</i> , <i>pgid</i> , <i>uid</i> , <i>gid</i> , <i>sid</i> , <i>taskid</i> , and <i>projid</i> . -n <i>increment</i> Specifies how the system scheduling priority of the specified process or processes is to be adjusted. The <i>increment</i> option-argument is a positive or negative decimal integer that will be used to modify the system scheduling priority of the specified

process or processes. Positive *increment* values cause a lower system scheduling priority. Negative *increment* values may require appropriate privileges and will cause a higher system scheduling priority.

- p Interprets all operands or just the *pid* arguments as unsigned decimal integer process IDs. The -p option is the default if no options are specified.
- u Interprets all operands or just the *user* argument as users. If a user exists with a user name equal to the operand, then the user ID of that user will be used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it will be used as the numeric user ID of the user.

OPERANDS The following operands are supported:

- ID* A process ID, process group ID or user name/user ID, depending on the option selected.
- priority* The value specified is taken as the actual system scheduling priority, rather than as an increment to the existing system scheduling priority. Specifying a scheduling priority higher than that of the existing process may require appropriate privileges.

EXAMPLES **EXAMPLE 1** Adjusting the scheduling priority of process IDs

Adjust the system scheduling priority so that process IDs 987 and 32 would have a lower scheduling priority:

```
example% renice -n 5 -p 987 32
```

EXAMPLE 2 Adjusting the scheduling priority of group IDs

Adjust the system scheduling priority so that group IDs 324 and 76 would have a higher scheduling priority, if the user has the appropriate privileges to do so:

```
example% renice -n -4 -g 324 76
```

EXAMPLE 3 Adjusting the scheduling priority of a user ID and user name

Adjust the system scheduling priority so that numeric user ID 8 and user *sas* would have a lower scheduling priority:

```
example% renice -n 4 -u 8 sas
```

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `renice`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

renice(1)

0 Successful completion.

>0 An error occurred.

FILES /etc/passwd map user names to user IDs

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

SEE ALSO `nice(1)`, `passwd(1)`, `priocntl(1)`, `attributes(5)`, `environ(5)`, `standards(5)`

NOTES The `renice` syntax

```
renice [-n increment] [-i idtype] ID ...
```

is preferred over the old syntax

```
renice [-n increment] [-g | -p | -u] ID ...
```

which is now obsolete.

If you make the priority very negative, then the process cannot be interrupted.

To regain control you must make the priority greater than 0.

Users other than the privileged user cannot increase scheduling priorities of their own processes, even if they were the ones that decreased the priorities in the first place.

The `priocntl` command subsumes the function of `renice`.

reset(1F)

NAME reset – reset the current form field to its default values

SYNOPSIS **reset**

DESCRIPTION The `reset` function changes the entry in a field of a form to its default value; that is, the value displayed when the form was opened.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`

rlogin(1)

NAME	rlogin – remote login
SYNOPSIS	rlogin [-8EL] [-ec] [-l <i>username</i>] <i>hostname</i>
DESCRIPTION	<p>rlogin establishes a remote login session from your terminal to the remote machine named <i>hostname</i>.</p> <p>Hostnames are listed in the <i>hosts</i> database, which may be contained in the <i>/etc/hosts</i> and <i>/etc/inet/ipnodes</i> files, the Network Information Service (NIS) <i>hosts</i> map, the Internet domain name server, or a combination of these. Each host has one official name (the first name in the database entry), and optionally one or more nicknames. Either official hostnames or nicknames may be specified in <i>hostname</i>.</p> <p>Each remote machine may have a file named <i>/etc/hosts.equiv</i> containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine may rlogin from the machines listed in the remote machine's <i>/etc/hosts.equiv</i> file without supplying a password. Individual users may set up a similar private equivalence list with the file <i>.rhosts</i> in their home directories. Each line in this file contains two names: a <i>hostname</i> and a <i>username</i> separated by a space. An entry in a remote user's <i>.rhosts</i> file permits the user named <i>username</i> who is logged into <i>hostname</i> to log in to the remote machine as the remote user without supplying a password. If the name of the local host is not found in the <i>/etc/hosts.equiv</i> file on the remote machine, and the local username and hostname are not found in the remote user's <i>.rhosts</i> file, then the remote machine will prompt for a password. Hostnames listed in <i>/etc/hosts.equiv</i> and <i>.rhosts</i> files must be the official hostnames listed in the hosts database; nicknames may not be used in either of these files.</p> <p>For security reasons, the <i>.rhosts</i> file must be owned by either the remote user or by root.</p> <p>The remote terminal type is the same as your local terminal type (as given in your environment <i>TERM</i> variable). The terminal or window size is also copied to the remote system if the server supports the option, and changes in size are reflected as well. All echoing takes place at the remote site, so that (except for delays) the remote login is transparent. Flow control using CTRL-S and CTRL-Q and flushing of input and output on interrupts are handled properly.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-8 Pass eight-bit data across the net instead of seven-bit data.-ec Specify a different escape character, <i>c</i>, for the line used to disconnect from the remote host.-E Stop any character from being recognized as an escape character.-l <i>username</i> Specify a different <i>username</i> for the remote login. If you do not use this option, the remote username used is the same as your local username.-L Allow the rlogin session to be run in "litout" mode.

Escape Sequences

Lines that you type which start with the tilde character are “escape sequences” (the escape character can be changed using the `-e` option):

- `~.` Disconnect from the remote host. This is not the same as a logout, because the local host breaks the connection with no warning to the remote end.
- `~susp` Suspend the login session (only if you are using a shell with Job Control). `susp` is your “suspend” character, usually CTRL-Z; see `tty(1)`.
- `~dsusp` Suspend the input half of the login, but output will still be seen (only if you are using a shell with Job Control). `dsusp` is your “deferred suspend” character, usually CTRL-Y; see `tty(1)`.

OPERANDS

hostname The remote machine on which *rlogin* establishes the remote login session.

FILES

- `/etc/passwd` contains information about users’ accounts
- `/usr/hosts/*` for *hostname* version of the command
- `/etc/hosts.equiv` list of trusted hostnames with shared usernames
- `/etc/nologin` message displayed to users attempting to login during machine shutdown
- `$HOME/.rhosts` private list of trusted hostname/username combinations
- `/etc/hosts` hosts database
- `/etc/inet/ipnodes` hosts database

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc

SEE ALSO

`rsh(1)`, `stty(1)`, `tty(1)`, `in.named(1M)`, `hosts(4)`, `ipnodes(4)`, `hosts.equiv(4)`, `nologin(4)`, `attributes(5)`

DIAGNOSTICS

The following message indicates that the machine is in the process of being shutdown and logins have been disabled:

```
NO LOGINS: System going down in N minutes
```

NOTES

When a system is listed in `hosts.equiv`, its security must be as good as local security. One insecure system listed in `hosts.equiv` can compromise the security of the entire system.

rlogin(1)

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP.) The functionality of the two remains the same; only the name has changed.

This implementation can only use the TCP network service.

NAME	rm, rmdir – remove directory entries
SYNOPSIS	<pre> /usr/bin/rm [-f] [-i] file... /usr/bin/rm -rR [-f] [-i] dirname... [file...] /usr/xpg4/bin/rm [-fiRr] file... /usr/bin/rmdir [-ps] dirname... </pre>
/usr/bin/rm /usr/xpg4/bin/rm	<p>The <code>rm</code> utility removes the directory entry specified by each <i>file</i> argument. If a file has no write permission and the standard input is a terminal, the full set of permissions (in octal) for the file are printed followed by a question mark. This is a prompt for confirmation. If the answer begins with <i>y</i> (for yes), the file is deleted, otherwise the file remains.</p> <p>If <i>file</i> is a symbolic link, the link will be removed, but the file or directory to which it refers will not be deleted. Users do not need write permission to remove a symbolic link, provided they have write permissions in the directory.</p> <p>If multiple <i>files</i> are specified and removal of a <i>file</i> fails for any reason, <code>rm</code> will write a diagnostic message to standard error, do nothing more to the current <i>file</i>, and go on to any remaining <i>files</i>.</p> <p>If the standard input is not a terminal, the utility will operate as if the <code>-f</code> option is in effect.</p>
/usr/bin/rmdir	<p>The <code>rmdir</code> utility will remove the directory entry specified by each <i>dirname</i> operand, which must refer to an empty directory.</p> <p>Directories will be processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of <code>rmdir</code>, the subdirectory must be specified before the parent directory so that the parent directory will be empty when <code>rmdir</code> tries to remove it.</p>
OPTIONS	<p>The following options are supported for <code>/usr/bin/rm</code> and <code>/usr/xpg4/bin/rm</code>:</p> <p><code>-r</code> Recursively removes directories and subdirectories in the argument list. The directory will be emptied of files and removed. The user is normally prompted for removal of any write-protected files which the directory contains. The write-protected files are removed without prompting, however, if the <code>-f</code> option is used, or if the standard input is not a terminal and the <code>-i</code> option is not used.</p> <p>Symbolic links that are encountered with this option will not be traversed.</p> <p>If the removal of a non-empty, write-protected directory is attempted, the utility will always fail (even if the <code>-f</code> option is used), resulting in an error message.</p> <p><code>-R</code> Same as <code>-r</code> option.</p>

rm(1)

/usr/bin/rm	The following options are supported for <code>/usr/bin/rm</code> only: <ul style="list-style-type: none">-f Removes all files (whether write-protected or not) in a directory without prompting the user. In a write-protected directory, however, files are never removed (whatever their permissions are), but no messages are displayed. If the removal of a write-protected directory is attempted, this option will not suppress an error message.-i Interactive. With this option, <code>rm</code> prompts for confirmation before removing any files. It overrides the <code>-f</code> option and remains in effect even if the standard input is not a terminal.
/usr/xpg4/bin/rm	The following options are supported for <code>/usr/xpg4/bin/rm</code> only: <ul style="list-style-type: none">-f Does not prompt for confirmation. Does not write diagnostic messages or modify the exit status in the case of non-existent operands. Any previous occurrences of the <code>-i</code> option will be ignored.-i Prompts for confirmation. Any occurrences of the <code>-f</code> option will be ignored.
/usr/bin/rmdir	The following options are supported for <code>/usr/bin/rmdir</code> only: <ul style="list-style-type: none">-p Allows users to remove the directory <i>dirname</i> and its parent directories which become empty. A message is printed to standard error if all or part of the path could not be removed.-s Suppresses the message printed on the standard error when <code>-p</code> is in effect.
OPERANDS	The following operands are supported: <ul style="list-style-type: none"><i>file</i> A path name of a directory entry to be removed.<i>dirname</i> A path name of an empty directory to be removed.
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>rm</code> and <code>rmdir</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
/usr/bin/rm /usr/xpg4/bin/rm	EXAMPLE 1 Removing directories The following command: <pre>example% rm a.out core</pre> removes the directory entries <code>a.out</code> and <code>core</code> . EXAMPLE 2 Removing a directory without prompting The following command: <pre>example% rm -rf junk</pre> removes the directory <code>junk</code> and all its contents, without prompting.

/usr/bin/rmdir **EXAMPLE 3** Removing empty directories

If a directory *a* in the current directory is empty, except that it contains a directory *b*, and *a/b* is empty except that it contains a directory *c*, the following command will remove all three directories:

```
example% rmdir -p a/b/c
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `rm` and `rmdir`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 If the `-f` option was not specified, all the named directory entries were removed; otherwise, all the existing named directory entries were removed.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

/usr/bin/rm
/usr/bin/rmdir

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

/usr/xpg4/bin/rm

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	enabled
Interface Stability	Standard

SEE ALSO

`rmdir(2)`, `unlink(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

DIAGNOSTICS

All messages are generally self-explanatory.

It is forbidden to remove the files `"."` and `".."` in order to avoid the consequences of inadvertently doing something like the following:

```
example% rm -r .*
```

NOTES

`A -` permits the user to mark explicitly the end of any command line options, allowing `rm` to recognize file arguments that begin with a `-`. As an aid to BSD migration, `rm` will accept `--` as a synonym for `-`. This migration aid may disappear in a future release. If `a -` and `a -` both appear on the same command line, the second will be interpreted as a file.

rmformat(1)

NAME	rmformat – removable rewritable media format utility								
SYNOPSIS	<pre>rmformat [-DeHpUv] [-b <i>label</i>] [-c <i>blockno</i>] [-Fquick long force] [-R enable disable] [-s <i>filename</i>] [-w enable disable] [-W enable disable] [<i>devname</i>] rmformat -V read write <i>devname</i></pre>								
DESCRIPTION	<p>The <code>rmformat</code> utility is used to format, label, partition, and perform other miscellaneous functions on removable, rewritable media that include floppy drives, IOMEGA Zip/Jaz products, and the PCMCIA memory and ata cards. This utility can also be used for the verification and surface analysis and for repair of the bad sectors found during verification if the drive or the driver supports bad block management.</p> <p><code>rmformat</code> provides functionality to read/write protect the media with or without a password. The password protection enabling or disabling is possible only with selective rewritable media such as the IOMEGA Zip/Jaz products.</p> <p>After formatting, <code>rmformat</code> writes the label, which covers the full capacity of the media as one slice on floppy and PCMCIA memory cards to maintain compatibility with the behavior of <code>fdformat</code>. On Zip/Jaz devices, the driver exports one slice covering the full capacity of the disk as default. <code>rmformat</code> does not write the label on Zip/Jaz media, unless explicitly requested. The partition information can be changed with the help of other options provided by <code>rmformat</code>.</p>								
OPTIONS	<p>The following options are supported:</p> <table><tr><td>-b <i>label</i></td><td>Labels the media with a SUNOS label. A SUNOS volume label name is restricted to 8 characters. For writing a DOS Volume label, the user should use <code>mkfs_pdfs(1M)</code>.</td></tr><tr><td>-c <i>blockno</i></td><td>Corrects and repairs the given block. This correct and repair option may not be applicable to all devices supported by <code>rmformat</code>, as some devices may have a drive with bad block management capability and others may have this option implemented in the driver. If the drive or driver supports bad block management, a best effort is made to rectify the bad block. If the bad block still cannot be rectified, a message is displayed to indicate the failure to repair. The block number can be provided in decimal, octal, or hexadecimal format.</td></tr><tr><td>-D</td><td>The normal floppy and PCMCIA memory and ata cards do not support bad block management.</td></tr><tr><td></td><td>Formats a 720KB (3.5 inch) double density diskette. This is the default for double density type drives. This option is needed if the drive is a high or extended-density type.</td></tr></table>	-b <i>label</i>	Labels the media with a SUNOS label. A SUNOS volume label name is restricted to 8 characters. For writing a DOS Volume label, the user should use <code>mkfs_pdfs(1M)</code> .	-c <i>blockno</i>	Corrects and repairs the given block. This correct and repair option may not be applicable to all devices supported by <code>rmformat</code> , as some devices may have a drive with bad block management capability and others may have this option implemented in the driver. If the drive or driver supports bad block management, a best effort is made to rectify the bad block. If the bad block still cannot be rectified, a message is displayed to indicate the failure to repair. The block number can be provided in decimal, octal, or hexadecimal format.	-D	The normal floppy and PCMCIA memory and ata cards do not support bad block management.		Formats a 720KB (3.5 inch) double density diskette. This is the default for double density type drives. This option is needed if the drive is a high or extended-density type.
-b <i>label</i>	Labels the media with a SUNOS label. A SUNOS volume label name is restricted to 8 characters. For writing a DOS Volume label, the user should use <code>mkfs_pdfs(1M)</code> .								
-c <i>blockno</i>	Corrects and repairs the given block. This correct and repair option may not be applicable to all devices supported by <code>rmformat</code> , as some devices may have a drive with bad block management capability and others may have this option implemented in the driver. If the drive or driver supports bad block management, a best effort is made to rectify the bad block. If the bad block still cannot be rectified, a message is displayed to indicate the failure to repair. The block number can be provided in decimal, octal, or hexadecimal format.								
-D	The normal floppy and PCMCIA memory and ata cards do not support bad block management.								
	Formats a 720KB (3.5 inch) double density diskette. This is the default for double density type drives. This option is needed if the drive is a high or extended-density type.								

- e Ejects the media upon completion. This feature may not be available if the drive does not support motorized eject.
- F quick | long | force Formats the media.
- The `quick` option starts a format without certification or format with limited certification of certain tracks on the media.
- The `long` option starts a complete format. For some devices this might include the certification of the whole media by the drive itself.
- The `force` option to format is provided to start a long format without user confirmation before the format is started. For drives which have a password protection mechanism, it clears the password while formatting. This feature is useful when a password is no longer available. On those media which do not have such password protection, `force` starts a long format.
- In legacy media such as floppy drives, all options start a long format depending on the mode (Extended Density mode, High Density mode, or Double Density mode) with which the floppy drive operates by default. On PCMCIA memory cards, all options start a long format.
- H Formats a 1.44 MB (3.5 inch) high density diskette. This is the default for high density type drives. It is needed if the drive is the Extended Density type.
- p Prints the protection status of the media. This option prints information whether the media is write, read, or password protected.
- R enable | disable Enables read/write protection with a password or disables the password read/write protection. This always works in interactive mode, as the password is requested from the user in an interactive manner to maintain security.
- A password length of 32 bytes (maximum) is allowed for the IOMEGA products that support this feature. This option is applicable only for IOMEGA products. IOMEGA products do not allow read/write protection

rmformat(1)

-s *filename*

without a password. On the devices which do not have such software read/write protect facility, warnings indicating the non-availability of this feature are provided.

Enables the user to lay out the partition information in the SUNOS label.

The user should provide a file as input with information about each slice in a format providing byte offset, size required, tags, and flags, as follows:

```
slices: n = offset, size [, flags, tags]
```

where *n* is the slice number, *offset* is the byte offset at which the slice *n* starts, and *size* is the required size for slice *n*. Both *offset* and *size* must be a multiple of 512 bytes. These numbers can be represented as decimal, hexadecimal, or octal numbers. No floating point numbers are accepted. Details about maximum number of slices can be obtained from the *System Administration Guide: Basic Administration*.

To specify the *size* or *offset* in kilobytes, megabytes, or gigabytes, add KB, MB, GB, respectively. A number without a suffix is assumed to be a byte offset. The flags are represented as follows:

```
wm = read-write, mountable  
wu = read-write, unmountable  
ru = read-only, unmountable
```

The tags are represented as follows: unassigned, boot, root, swap, usr, backup, stand, var, home, alternates.

The tags and flags can be omitted from the four tuple when finer control on those values is not required. It is required to omit both or include both. If the tags and flags are omitted from the four tuple for a particular slice, a default value for each is assumed. The default value for flags is *wm* and for tags is *unassigned*.

Either full tag names can be provided or an abbreviation for the tags can be used. The abbreviations can be the first two or more letters from the standard tag names. *rmformat* is case insensitive in handling the defined tags & flags.

Slice specifications are separated by :

For example:

```
slices: 0 = 0, 30MB, "wm", "home" :
        1 = 30MB, 51MB :
        2 = 0, 100MB, "wm", "backup" :
        6 = 81MB, 19MB
```

rmformat does the necessary checking to detect any overlapping partitions or illegal requests to addresses beyond the capacity of the media under consideration. There can be only one slice information entry for each slice *n*. If multiple slice information entries for the same slice *n* is provided, an appropriate error message is displayed. The slice 2 is the backup slice covering the whole disk capacity. The pound sign character, #, can be used to describe a line of comments in the input file. If the line starts with #, then rmformat ignores all the characters following # until the end of the line.

Partitioning some of the media with very small capacity is permitted, but be cautious in using this option on such devices.

-U

Performs umount on any file systems and then formats. See mount(1M). This option unmounts all the mounted slices and issues a long format on the device requested.

-V read | write

Verifies each block of media after format. The write verification is a destructive mechanism. The user is queried for confirmation before the verification is started. The output of this option is a list of block numbers, which are identified as bad.

The read verification only verifies the blocks and report the blocks which are prone to errors.

The list of block numbers displayed can be used with the -c option for repairing.

-w enable | disable

Enables or disables the write protection on media. On devices that do not have a software write protect facility, a message indicating non-availability of this feature is displayed.

-W enable | disable

Enables or disables write protection with password. This option always works in interactive mode, as a password is requested from the user to maintain security.

rmformat(1)

A maximum password length of 32 bytes is allowed for IOMEGA products that support this feature. On devices that do not have the write protection with password, the software displays appropriate messages indicating the non-availability of such features.

OPERANDS The following operand is supported:

devname

devname can be provided as absolute device pathname or relative pathname for the device from the current working directory or the nickname as exported by the System Volume manager. See `vold(1M)`.

For floppy devices, to access the first drive use `/dev/rdiskette0` (for systems without volume management) or `floppy0` (for systems with volume management). Specify `/dev/rdiskette1` (for systems without volume management) or `floppy1` (for systems with volume management) to use the second drive.

For systems without volume management running, the user can also provide the absolute device pathname as `/dev/rdisk/c?t?d?s?` or the appropriate relative device pathname from the current working directory.

EXAMPLES

EXAMPLE 1 Formatting a diskette

```
example$ rmformat -F quick /dev/rdiskette
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
```

EXAMPLE 2 Formatting a Zip drive

```
example$ rmformat -F quick /vol/dev/aliases/zip0
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
```

EXAMPLE 3 Formatting a diskette for a UFS file system

The following example formats a diskette and creates a UFS file system:

```
example$ rmformat -F quick /vol/dev/aliases/floppy0
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
example$ su
# /usr/sbin/newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /dev/rdiskette: (y/n)? y
/dev/rdiskette: 2880 sectors in 80 cylinders of 2 tracks, 18 sectors
      1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
      32, 640, 1184, 1792, 2336,
```

EXAMPLE 3 Formatting a diskette for a UFS file system (Continued)

#

EXAMPLE 4 Formatting removable media for a PCFS file system

The following example shows how to create an alternate `fdisk` partition:

```
example$ rmformat -F quick /dev/rdisk/c0t4d0s2:c
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
example$ su
# fdisk /dev/rdisk/c0t4d0s2:c
# mkfs -F pcfs /dev/rdisk/c0t4d0s2:c
Construct a new FAT file system on /dev/rdisk/c0t4d0s2:c: (y/n)? y
#
```

The following example describes how to create a PCFS file system *without* an `fdisk` partition:

```
example$ rmformat -F quick /dev/rdiskette
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
example$ su
# mkfs -F pcfs -o nofdisk,size=2 /dev/rdiskette
Construct a new FAT file system on /dev/rdiskette: (y/n)? y
#
```

EXAMPLE 5 Enabling or disabling read or write protection

The following example shows how to enable write protection and set a password on a Zip drive:

```
example$ rmformat -W enable /vol/dev/aliases/zip0
Please enter password (32 chars maximum): xxx
Please reenter password: xxx
```

The following example shows how to disable write protection and remove the password on a Zip drive:

```
example$ rmformat -W disable /vol/dev/aliases/zip0
Please enter password (32 chars maximum): xxx
```

The following example shows how to enable read protection and set a password on a Zip drive:

```
example$ rmformat -R enable /vol/dev/aliases/zip0
Please enter password (32 chars maximum): xxx
Please reenter password: xxx
```

The following example shows how to disable read protection and remove the password on a Zip drive:

rmformat(1)

EXAMPLE 5 Enabling or disabling read or write protection *(Continued)*

```
example$ rmformat -R disable /vol/dev/aliases/zip0
Please enter password (32 chars maximum): xxx
```

System Administration Guide: Basic Administration

NOTES A rewritable media or PCMCIA memory card or PCMCIA ata card containing a `ufs` file system created on a SPARC-based system (using `newfs(1M)`) is not identical to a rewritable media or PCMCIA memory card containing a `ufs` file system created on an IA based system. Do not interchange any removable media containing `ufs` between these platforms; use `cpio(1)` or `tar(1)` to transfer files on diskettes or memory cards between them. For interchangeable filesystems refer to `pcfs(7FS)` and `udfs(7FS)`.

BUGS Currently, bad sector mapping is not supported on floppy diskettes or PCMCIA memory cards. Therefore, a diskette or memory card is unusable if `rmformat` finds an error (`bad sector`).

roffbib(1)

NAME	roffbib – format and print a bibliographic database
SYNOPSIS	roffbib [-e] [-h] [-m <i>filename</i>] [-np] [-olist] [-Q] [-ra <i>N</i>] [-s <i>N</i>] [-T <i>term</i>] [-V] [-x] [<i>filename</i>] ...
DESCRIPTION	<p>roffbib prints out all records in a bibliographic database, in bibliography format rather than as footnotes or endnotes. Generally it is used in conjunction with sortbib(1):</p> <pre>example% sortbib database roffbib</pre>
OPTIONS	<p>roffbib accepts all options understood by nroff(1) except -i and -q.</p> <p>-e Produce equally-spaced words in adjusted lines using full terminal resolution.</p> <p>-h Use output tabs during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.</p> <p>-m <i>filename</i> Prepend the macro file /usr/share/lib/tmac/tmac.name to the input files. There should be a space between the -m and the macro filename. This set of macros will replace the ones defined in /usr/share/lib/tmac/tmac.bib.</p> <p>-np Number first generated page <i>p</i>.</p> <p>-olist Print only page numbers that appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N-M</i> means pages <i>N</i> through <i>M</i>; an initial -<i>N</i> means from the beginning to page <i>N</i>; a final <i>N-</i> means from page <i>N</i> to end.</p> <p>-Q Queue output for the phototypesetter. Page offset is set to 1 inch.</p> <p>-ra<i>N</i> Set register <i>a</i> (one-character) to <i>N</i>. The command-line argument -r<i>N</i>1 will number the references starting at 1.</p> <p> Four command-line registers control formatting style of the bibliography, much like the number registers of ms(5). The flag -rV2 will double space the bibliography, while -rV1 will double space references but single space annotation paragraphs. The line length can be changed from the default 6.5 inches to 6 inches with the -rL6i argument, and the page offset can be set from the default of 0 to one inch by specifying -rO1i (capital O, not zero).</p> <p>-s<i>N</i> Halt prior to every <i>N</i> pages for paper loading or changing (default <i>N</i> =1). To resume, enter NEWLINE or RETURN.</p> <p>-T<i>term</i> Specify <i>term</i> as the terminal type.</p> <p>-V Send output to the Versatec. Page offset is set to 1 inch.</p>

roffbib(1)

-x If abstracts or comments are entered following the %X field key, roffbib will format them into paragraphs for an annotated bibliography. Several %X fields may be given if several annotation paragraphs are desired.

FILES /usr/share/lib/tmac/tmac.bib file of macros used by nroff/troff

BUGS Users have to rewrite macros to create customized formats.

roles(1)

NAME	roles – print roles granted to a user				
SYNOPSIS	roles [<i>user</i> ...]				
DESCRIPTION	<p>The command <code>roles</code> prints on standard output the roles that you or the optionally-specified user have been granted. Roles are special accounts that correspond to a functional responsibility rather than to an actual person (referred to as a normal user).</p> <p>Each user may have zero or more roles. Roles have most of the attributes of normal users and are identified like normal users in <code>passwd(4)</code> and <code>shadow(4)</code>. Each role must have an entry in the <code>user_attr(4)</code> file that identifies it as a role. Roles can have their own authorizations and profiles. See <code>auths(1)</code> and <code>profiles(1)</code>.</p> <p>Roles are not allowed to log into a system as a primary user. Instead, a user must log in as him— or herself and assume the role. The actions of a role are attributable to the normal user. When auditing is enabled, the audited events of the role contain the audit ID of the original user who assumed the role.</p> <p>A role may not assume itself or any other role. Roles are not hierarchical. However, rights profiles (see <code>prof_attr(4)</code>) are hierarchical and can be used to achieve the same effect as hierarchical roles.</p> <p>Roles must have valid passwords and one of the shells that interprets profiles: either <code>pfcsch</code>, <code>pfksh</code>, or <code>pfsh</code>. See <code>pfexec(1)</code>.</p> <p>Role assumption may be performed using <code>su(1M)</code>, <code>rlogin(1)</code>, or some other service that supports the <code>PAM_RUSER</code> variable. Successful assumption requires knowledge of the role's password and membership in the role. Role assignments are specified in <code>user_attr(4)</code>.</p>				
EXAMPLES	<p>EXAMPLE 1 Sample output</p> <p>The output of the <code>roles</code> command has the following form:</p> <pre>example% roles tester01 tester02 tester01 : admin tester02 : secadmin, root example%</pre>				
EXIT STATUS	<p>The following exit values are returned:</p> <table><tr><td>0</td><td>Successful completion.</td></tr><tr><td>1</td><td>An error occurred.</td></tr></table>	0	Successful completion.	1	An error occurred.
0	Successful completion.				
1	An error occurred.				
FILES	<p><code>/etc/user_attr</code></p> <p><code>/etc/security/auth_attr</code></p> <p><code>/etc/security/prof_attr</code></p>

rpcgen(1)

NAME	<code>rpcgen</code> – an RPC protocol compiler
SYNOPSIS	<pre>rpcgen <i>infile</i> rpcgen [-a] [-A] [-b] [-C] [-D <i>name</i> [= <i>value</i>]] [-i <i>size</i>] [-I [-K <i>seconds</i>]] [-L] [-M] [-N] [-T] [-v] [-Y <i>pathname</i>] <i>infile</i> rpcgen [-c -h -l -m -t -Sc -Ss -Sm] [-o <i>outfile</i>] [<i>infile</i>] rpcgen [-s <i>nettype</i>] [-o <i>outfile</i>] [<i>infile</i>] rpcgen [-n <i>netid</i>] [-o <i>outfile</i>] [<i>infile</i>]</pre>
DESCRIPTION	<p>The <code>rpcgen</code> utility is a tool that generates C code to implement an RPC protocol. The input to <code>rpcgen</code> is a language similar to C known as RPC Language (Remote Procedure Call Language).</p> <p>The <code>rpcgen</code> utility is normally used as in the first synopsis where it takes an input file and generates three output files. If the <i>infile</i> is named <code>proto.x</code>, then <code>rpcgen</code> generates a header in <code>proto.h</code>, XDR routines in <code>proto_xdr.c</code>, server-side stubs in <code>proto_svc.c</code>, and client-side stubs in <code>proto_clnt.c</code>. With the <code>-T</code> option, it also generates the RPC dispatch table in <code>proto_tbl.i</code>.</p> <p><code>rpcgen</code> can also generate sample client and server files that can be customized to suit a particular application. The <code>-Sc</code>, <code>-Ss</code>, and <code>-Sm</code> options generate sample client, server and makefile, respectively. The <code>-a</code> option generates all files, including sample files. If the <i>infile</i> is <code>proto.x</code>, then the client side sample file is written to <code>proto_client.c</code>, the server side sample file to <code>proto_server.c</code> and the sample makefile to <code>makefile.proto</code>.</p> <p>The server created can be started both by the port monitors (for example, <code>inetd</code> or <code>listen</code>) or by itself. When it is started by a port monitor, it creates servers only for the transport for which the file descriptor 0 was passed. The name of the transport must be specified by setting up the environment variable <code>PM_TRANSPORT</code>. When the server generated by <code>rpcgen</code> is executed, it creates server handles for all the transports specified in the <code>NETPATH</code> environment variable, or if it is unset, it creates server handles for all the visible transports from the <code>/etc/netconfig</code> file. Note: the transports are chosen at run time and not at compile time. When the server is self-started, it backgrounds itself by default. A special define symbol <code>RPC_SVC_FG</code> can be used to run the server process in foreground.</p> <p>The second synopsis provides special features which allow for the creation of more sophisticated RPC servers. These features include support for user-provided <code>#defines</code> and RPC dispatch tables. The entries in the RPC dispatch table contain:</p> <ul style="list-style-type: none">■ pointers to the service routine corresponding to that procedure■ a pointer to the input and output arguments■ the size of these routines <p>A server can use the dispatch table to check authorization and then to execute the service routine. A client library may use the dispatch table to deal with the details of storage management and XDR data conversion.</p>

The other three synopses shown above are used when one does not want to generate all the output files, but only a particular one. See the EXAMPLES section below for examples of `rpcgen` usage. When `rpcgen` is executed with the `-s` option, it creates servers for that particular class of transports. When executed with the `-n` option, it creates a server for the transport specified by *netid*. If *infile* is not specified, `rpcgen` accepts the standard input.

All the options mentioned in the second synopsis can be used with the other three synopses, but the changes will be made only to the specified output file.

The C preprocessor `cc -E` is run on the input file before it is actually interpreted by `rpcgen`. For each type of output file, `rpcgen` defines a special preprocessor symbol for use by the `rpcgen` programmer:

<code>RPC_HDR</code>	defined when compiling into headers
<code>RPC_XDR</code>	defined when compiling into XDR routines
<code>RPC_SVC</code>	defined when compiling into server-side stubs
<code>RPC_CLNT</code>	defined when compiling into client-side stubs
<code>RPC_TBL</code>	defined when compiling into RPC dispatch tables

Any line beginning with “%” is passed directly into the output file, uninterpreted by `rpcgen`, except that the leading “%” is stripped off. To specify the path name of the C preprocessor, use the `-Y` flag.

For every data type referred to in *infile*, `rpcgen` assumes that there exists a routine with the string `xdr_` prepended to the name of the data type. If this routine does not exist in the RPC/XDR library, it must be provided. Providing an undefined data type allows customization of XDR routines.

OPTIONS

The following options are supported:

- `-a` Generates all files, including sample files.
- `-A` Enables the Automatic MT mode in the server main program. In this mode, the RPC library automatically creates threads to service client requests. This option generates multithread-safe stubs by implicitly turning on the `-M` option. Server multithreading modes and parameters can be set using the `rpc_control(3NSL)` call. `rpcgen` generated code does not change the default values for the Automatic MT mode.
- `-b` Backward compatibility mode. Generates transport-specific RPC code for older versions of the operating system.
- `-c` Compiles into XDR routines.
- `-C` Generates header and stub files which can be used with ANSI C compilers. Headers generated with this flag can also be used with C++ programs.

rpcgen(1)

-D <i>name</i> [= <i>value</i>]	Defines a symbol <i>name</i> . Equivalent to the <code>#define</code> directive in the source. If no <i>value</i> is given, <i>value</i> is defined as 1. This option may be specified more than once.
-h	Compiles into C data-definitions (a header). The <code>-T</code> option can be used in conjunction to produce a header which supports RPC dispatch tables.
-i <i>size</i>	Size at which to start generating inline code. This option is useful for optimization. The default <i>size</i> is 5.
-I	Compiles support for <code>inetd(1M)</code> in the server side stubs. Such servers can be self-started or can be started by <code>inetd</code> . When the server is self-started, it backgrounds itself by default. A special define symbol <code>RPC_SVC_FG</code> can be used to run the server process in foreground, or the user may simply compile without the <code>-I</code> option. If there are no pending client requests, the <code>inetd</code> servers exit after 120 seconds (default). The default can be changed with the <code>-K</code> option. All of the error messages for <code>inetd</code> servers are always logged with <code>syslog(3C)</code> . <i>Note:</i> This option is supported for backward compatibility only. It should always be used in conjunction with the <code>-b</code> option which generates backward compatibility code. By default (that is, when <code>-b</code> is not specified), <code>rpcgen</code> generates servers that can be invoked through portmonitors.
-K <i>seconds</i>	By default, services created using <code>rpcgen</code> and invoked through port monitors wait 120 seconds after servicing a request before exiting. That interval can be changed using the <code>-K</code> flag. To create a server that exits immediately upon servicing a request, use <code>-K 0</code> . To create a server that never exits, the appropriate argument is <code>-K -1</code> . When monitoring for a server, some portmonitors, like <code>listen(1M)</code> , <i>always</i> spawn a new process in response to a service request. If it is known that a server will be used with such a monitor, the server should exit immediately on completion. For such servers, <code>rpcgen</code> should be used with <code>-K 0</code> .
-l	Compiles into client-side stubs.
-L	When the servers are started in foreground, uses <code>syslog(3C)</code> to log the server errors instead of printing them on the standard error.

-m	Compiles into server-side stubs, but do not generate a “main” routine. This option is useful for doing callback-routines and for users who need to write their own “main” routine to do initialization.
-M	Generates multithread-safe stubs for passing arguments and results between rpcgen-generated code and user written code. This option is useful for users who want to use threads in their code.
-N	This option allows procedures to have multiple arguments. It also uses the style of parameter passing that closely resembles C. So, when passing an argument to a remote procedure, you do not have to pass a pointer to the argument, but can pass the argument itself. This behavior is different from the old style of rpcgen-generated code. To maintain backward compatibility, this option is not the default.
-n <i>netid</i>	Compiles into server-side stubs for the transport specified by <i>netid</i> . There should be an entry for <i>netid</i> in the <code>netconfig</code> database. This option may be specified more than once, so as to compile a server that serves multiple transports.
-o <i>outfile</i>	Specifies the name of the output file. If none is specified, standard output is used (-c, -h, -l, -m, -n, -s, -Sc, -Sm, -Ss, and -t modes only).
-s <i>nettype</i>	Compiles into server-side stubs for all the transports belonging to the class <i>nettype</i> . The supported classes are <code>netpath</code> , <code>visible</code> , <code>circuit_n</code> , <code>circuit_v</code> , <code>datagram_n</code> , <code>datagram_v</code> , <code>tcp</code> , and <code>udp</code> (see <code>rpc(3NSL)</code> for the meanings associated with these classes). This option may be specified more than once. <i>Note:</i> The transports are chosen at run time and not at compile time.
-Sc	Generates sample client code that uses remote procedure calls.
-Sm	Generates a sample Makefile which can be used for compiling the application.
-Ss	Generates sample server code that uses remote procedure calls.
-t	Compiles into RPC dispatch table.
-T	Generates the code to support RPC dispatch tables.
	The options -c, -h, -l, -m, -s, -Sc, -Sm, -Ss, and -t are used exclusively to generate a particular type of file, while the options -D and -T are global and can be used with the other options.
-v	Displays the version number.
-Y <i>pathname</i>	Gives the name of the directory where rpcgen will start looking for the C preprocessor.

rpcgen(1)

OPERANDS The following operand is supported:

infile input file

EXAMPLES **EXAMPLE 1** Generating the output files and dispatch table

The following entry

```
example% rpcgen -T prot.x
```

generates all the five files: *prot.h*, *prot_clnt.c*, *prot_svc.c*, *prot_xdr.c*, and *prot_tbl.i*.

EXAMPLE 2 Sending headers to standard output

The following example sends the C data-definitions (header) to the standard output:

```
example% rpcgen -h prot.x
```

EXAMPLE 3 Sending a test version

To send the test version of the *-DTEST*, server side stubs for all the transport belonging to the class *datagram_n* to standard output, use:

```
example% rpcgen -s datagram_n -DTEST prot.x
```

EXAMPLE 4 Creating server side stubs

To create the server side stubs for the transport indicated by *netid* *tcp*, use:

```
example% rpcgen -n tcp -o prot_svc.c prot.x
```

EXIT STATUS 0 Successful operation.

>0 An error occurred.

NAME	rpm2cpio – convert Red Hat Package (RPM) to cpio archive				
SYNOPSIS	rpm2cpio [<i>file.rpm</i>]				
DESCRIPTION	The rpm2cpio utility converts the .rpm file specified as its sole argument to a cpio archive on standard output. (See NOTES.) If no argument is given, an rpm stream is read from standard input. In both cases, rpm2cpio will fail and print a usage message if the standard output is a terminal. Therefore, the output is usually redirected to a file or piped through the cpio(1) utility.				
EXAMPLES	<p>EXAMPLE 1 Converting an rpm file</p> <pre>example% rpm2cpio Device3Dfx-1.1-2.src.rpm cpio -itv CPIO archive found! -rw-r--r-- 1 root root 2635 Sep 13 16:39 1998, 3dfx.gif -rw-r--r-- 1 root root 11339 Sep 27 16:03 1998, Dev3Dfx.tar.gz -rw-r--r-- 1 root root 1387 Sep 27 16:04 1998, Device3Dfx-1.1-2.spec 31 blocks</pre> <p>EXAMPLE 2 Converting from standard input</p> <pre>example% rpm2cpio < Device3Dfx-1.1-2.src.rpm cpio -itv CPIO archive found! -rw-r--r-- 1 root root 2635 Sep 13 16:39 1998, 3dfx.gif -rw-r--r-- 1 root root 11339 Sep 27 16:03 1998, Dev3Dfx.tar.gz -rw-r--r-- 1 root root 1387 Sep 27 16:04 1998, Device3Dfx-1.1-2.spec 31 blocks</pre>

	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWrpm</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrpm
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWrpm				
SEE ALSO	cpio(1), attributes(5)				
NOTES	rpm2cpio handles versions 3 and 4 RPMs.				

rsh(1)

NAME	rsh, remsh, remote_shell – remote shell
SYNOPSIS	rsh [-n] [-l <i>username</i>] <i>hostname</i> <i>command</i> rsh <i>hostname</i> [-n] [-l <i>username</i>] <i>command</i> remsh [-n] [-l <i>username</i>] <i>hostname</i> <i>command</i> remsh <i>hostname</i> [-n] [-l <i>username</i>] <i>command</i> <i>hostname</i> [-n] [-l <i>username</i>] <i>command</i>
DESCRIPTION	<p>rsh connects to the specified <i>hostname</i> and executes the specified <i>command</i>. rsh copies its standard input to the remote command, the standard output of the remote command to its standard output, and the standard error of the remote command to its standard error. Interrupt, quit, and terminate signals are propagated to the remote command. rsh normally terminates when the remote command does.</p> <p>If you omit <i>command</i>, instead of executing a single command, rsh logs you in on the remote host using rlogin(1).</p> <p>rsh will not return the exit status code of <i>command</i>.</p> <p>Shell metacharacters which are not quoted are interpreted on the local machine, while quoted metacharacters are interpreted on the remote machine. See EXAMPLES.</p> <p>If there is no locale setting in the initialization file of the login shell (.cshrc, . . .) for a particular user, rsh always executes the command in the "C" locale instead of using the default locale of the remote machine.</p>
OPTIONS	<p>The following options are supported:</p> <p>-l <i>username</i> Uses <i>username</i> as the remote username instead of your local username. In the absence of this option, the remote username is the same as your local username.</p> <p>-n Redirects the input of rsh to /dev/null. You sometimes need this option to avoid unfortunate interactions between rsh and the shell which invokes it. For example, if you are running rsh and invoke a rsh in the background without redirecting its input away from the terminal, it will block even if no reads are posted by the remote command. The -n option will prevent this.</p> <p>The type of remote shell (sh, rsh, or other) is determined by the user's entry in the file /etc/passwd on the remote system.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>command</i> The command to be executed on the specified <i>hostname</i>.</p>
USAGE	See largefile(5) for the description of the behavior of rsh and remsh when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).

The `rsh` and `remsh` commands are IPv6-enabled. See `ip6(7P)`.

Hostnames are given in the `hosts` database, which may be contained in the `/etc/hosts` file, the Internet domain name database, or both. Each host has one official name (the first name in the database entry) and optionally one or more nicknames. Official hostnames or nicknames may be given as `hostname`.

If the name of the file from which `rsh` is executed is anything other than `rsh`, `rsh` takes this name as its `hostname` argument. This allows you to create a symbolic link to `rsh` in the name of a host which, when executed, will invoke a remote shell on that host. By creating a directory and populating it with symbolic links in the names of commonly used hosts, then including the directory in your shell's search path, you can run `rsh` by typing `hostname` to your shell.

If `rsh` is invoked with the basename `remsh`, `rsh` will check for the existence of the file `/usr/bin/remsh`. If this file exists, `rsh` will behave as if `remsh` is an alias for `rsh`. If `/usr/bin/remsh` does not exist, `rsh` will behave as if `remsh` is a host name.

Each remote machine may have a file named `/etc/hosts.equiv` containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine may run `rsh` from the machines listed in the remote machine's `/etc/hosts` file. Individual users may set up a similar private equivalence list with the file `.rhosts` in their home directories. Each line in this file contains two names: a `hostname` and a `username` separated by a space. The entry permits the user named `username` who is logged into `hostname` to use `rsh` to access the remote machine as the remote user. If the name of the local host is not found in the `/etc/hosts.equiv` file on the remote machine, and the local username and hostname are not found in the remote user's `.rhosts` file, then the access is denied. The hostnames listed in the `/etc/hosts.equiv` and `.rhosts` files must be the official hostnames listed in the `hosts` database; nicknames may not be used in either of these files.

You cannot log in using `rsh` as a trusted user from a trusted hostname if the trusted user account is locked.

`rsh` will not prompt for a password if access is denied on the remote machine unless the `command` argument is omitted.

EXAMPLES **EXAMPLE 1** Using `rsh` to append files

The following command:

```
example% rsh lizard cat lizard.file >> example.file
```

appends the remote file `lizard.file` from the machine called `lizard` to the file called `example.file` on the machine called `example`, while the command:

```
example% rsh lizard cat lizard.file ">>" lizard.file2
```

rsh(1)

EXAMPLE 1 Using rsh to append files (Continued)

appends the file `lizard.file` on the machine called `lizard` to the file `lizard.file2` which also resides on the machine called `lizard`.

EXIT STATUS The following exit values are returned:

0 Successful completion.

1 An error occurred.

FILES

<code>/etc/hosts</code>	Internet host table
<code>/etc/hosts.equiv</code>	trusted remote hosts and users
<code>/etc/passwd</code>	system password file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc
CSI	enabled

SEE ALSO `on(1)`, `rlogin(1)`, `telnet(1)`, `vi(1)`, `in.named(1M)`, `hosts(4)`, `hosts.equiv(4)`, `ipnodes(4)`, `attributes(5)`, `largefile(5)`, `ip6(7P)`

NOTES When a system is listed in `hosts.equiv`, its security must be as good as local security. One insecure system listed in `hosts.equiv` can compromise the security of the entire system.

You cannot run an interactive command (such as `vi(1)`). Use `rlogin` if you wish to do this.

Stop signals stop the local `rsh` process only. This is arguably wrong, but currently hard to fix for reasons too complicated to explain here.

The current local environment is not passed to the remote shell.

Sometimes the `-n` option is needed for reasons that are less than obvious. For example, the command:

```
example% rsh somehost dd if=/dev/nrmt0 bs=20b | tar xvpBf -
```

will put your shell into a strange state. Evidently, what happens is that the `tar` terminates before the `rsh`. The `rsh` then tries to write into the "broken pipe" and, instead of terminating neatly, proceeds to compete with your shell for its standard input. Invoking `rsh` with the `-n` option avoids such incidents.

This bug occurs only when `rsh` is at the beginning of a pipeline and is not reading standard input. Do not use the `-n` if `rsh` actually needs to read standard input. For example:

```
example% tar cf - . | rsh sundial dd of=/dev/rmt0 obs=20b
```

does not produce the bug. If you were to use the `-n` in a case like this, `rsh` would incorrectly read from `/dev/null` instead of from the pipe.

run(1F)

NAME	run – run an executable
SYNOPSIS	run [-s] [-e] [-n] [-t <i>string</i>] <i>program</i>
DESCRIPTION	The run command runs <i>program</i> , using the <code>PATH</code> variable to find it. By default, when <i>program</i> has completed, the user is prompted (Press ENTER to continue:), before being returned to FMLI. The argument <i>program</i> is a system executable followed by its options (if any).
OPTIONS	The following options are supported: -e If -e is specified, the user will be prompted before returning to FMLI only if there is an error condition -n If -n is specified, the user will never be prompted before returning to FMLI (useful for programs like vi, in which the user must do some specific action to exit in the first place). -s The -s option means "silent", implying that the screen will not have to be repainted when <i>program</i> has completed. Note that the -s option should only be used when <i>program</i> does not write to the terminal. In addition, when -s is used, <i>program</i> cannot be interrupted, even if it recognizes interrupts. -t <i>string</i> If -t is specified, <i>string</i> is the name this process will have in the pop-up menu generated by the frm-list command. This feature requires the executable facesuspend (see face(1)) to suspend the process and return to the FMLI application.

EXAMPLES

EXAMPLE 1 Sample output of run command

Here is a menu that uses run:

```
menu="Edit special System files"
name="Password file"
action='run -e vi /etc/passwd`
name="Group file"
action='run -e vi /etc/group`
name="My .profile"
action='run -n vi $HOME/.profile`
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

run(1F)

SEE ALSO | face(1), attributes(5)

runat(1)

NAME	runat – execute command in extended attribute name space				
SYNOPSIS	<code>/usr/bin/runat file [command]</code>				
DESCRIPTION	<p>The runat utility is used to execute shell commands in a file's hidden attribute directory. Effectively, this utility changes the current working directory to be the hidden attribute directory associated with the file argument and then executes the specified command in the bourne shell (<code>/bin/sh</code>). If no command argument is provided, an interactive shell is spawned. The environment variable <code>\$SHELL</code> defines the shell to be spawned. If this variable is undefined, the default shell, <code>/bin/sh</code>, is used.</p> <p>The file argument can be any file, including a directory, that can support extended attributes. It is not necessary that this file have any attributes (or be prepared in any way) before invoking the runat command.</p>				
OPERANDS	<p>The following operands are supported:</p> <table><tr><td><i>file</i></td><td>Any file, including a directory, that can support extended attributes.</td></tr><tr><td><i>command</i></td><td>The command to be executed in an attribute directory.</td></tr></table>	<i>file</i>	Any file, including a directory, that can support extended attributes.	<i>command</i>	The command to be executed in an attribute directory.
<i>file</i>	Any file, including a directory, that can support extended attributes.				
<i>command</i>	The command to be executed in an attribute directory.				
ERRORS	A non-zero exit status will be returned if runat cannot access the <i>file</i> argument, or the <i>file</i> argument does not support extended attributes.				
USAGE	<p>See <code>fsattr(5)</code> for a detailed description of extended file attributes.</p> <p>The process context created by the runat command has its current working directory set to the hidden directory containing the file's extended attributes. The parent of this directory (the <code>..</code> entry) always refers to the file provided on the command line. As such, it may not be a directory. Therefore, commands (such as <code>pwd</code>) that depend upon the parent entry being well-formed (that is, referring to a directory) may fail.</p> <p>In the absence of the <i>command</i> argument, runat will spawn a new interactive shell with its current working directory set to be the provided file's hidden attribute directory. Notice that some shells (such as <code>zsh</code> and <code>tcsh</code>) are not well behaved when the directory parent is not a directory, as described above. These shells should not be used with runat.</p>				
EXAMPLES	<p>EXAMPLE 1 Using runat to list extended attributes on a file</p> <pre>example% runat file.1 ls -l example% runat file.1 ls</pre> <p>EXAMPLE 2 Creating extended attributes</p> <pre>example% runat file.2 cp /tmp/attrdata attr.1 example% runat file.2 cat /tmp/attrdata > attr.1</pre>				

EXAMPLE 3 Copying an attribute from one file to another

```
example% runat file.2 cat attr.1 | runat file.1 "cat > attr.1"
```

EXAMPLE 4 Using runat to spawn an interactive shell

```
example% runat file.3 /bin/sh
```

This spawns a new shell in the attribute directory for `file.3`. Notice that the shell will not be able to determine what your current directory is. To leave the attribute directory, either exit the spawned shell or change directory (`cd`) using an absolute path.

Recommended methods for performing basic attribute operations:

display

```
runat file ls [options]
```

read

```
runat file cat attribute
```

create/modify

```
runat file cp absolute-file-path attribute
```

delete

```
runat file rm attribute
```

permission changes

```
runat file chmod mode attribute
```

```
runat file chgrp group attribute
```

```
runat file chown owner attribute
```

interactive shell

```
runat file /bin/sh
```

or set your `$SHELL` to `/bin/sh` and

```
runat file
```

The above list of commands are known to work with `runat`. While many other commands may work, there is no guarantee that any beyond this list will work. Any command that relies on being able to determine its current working directory is likely to fail. Examples of such commands follow:

EXAMPLE 5 Using `man` in an attribute directory

```
example% runat file.1 man runat
getcwd: Not a directory
```

EXAMPLE 6 Spawning a `tcsh` shell in an attribute directory

```
example% runat file.3 /usr/bin/tcsh
tcsh: Not a directory
tcsh: Trying to start from "/home/user"
```

runat(1)

EXAMPLE 6 Spawning a tcsh shell in an attribute directory (Continued)

A new tcsh shell has been spawned with the current working directory set to the user's home directory.

EXAMPLE 7 Spawning a zsh shell in an attribute directory

```
example% runat file.3 /usr/bin/zsh
example%
```

While the command appears to have worked, zsh has actually just changed the current working directory to '/'. This can be seen by using /bin/pwd:

```
example% /bin/pwd
/
```

ENVIRONMENT VARIABLES EXIT STATUS

SHELL Specifies the command shell to be invoked by runat.

The following exit values are returned:

125 The attribute directory of the file referenced by the *file* argument cannot be accessed.

126 The exec of the provided *command* argument failed.

Otherwise, the exit status returned is the exit status of the shell invoked to execute the provided command.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Evolving

SEE ALSO

`open(2)`, `attributes(5)`, `fsattr(5)`

NOTES

It is not always obvious why a command fails in runat when it is unable to determine the current working directory. The errors resulting can be confusing and ambiguous (see the tcsh and zsh examples above).

NAME	rup – show host status of remote machines (RPC version)				
SYNOPSIS	rup [-hlt] rup [host...]				
DESCRIPTION	<p>rup gives a status similar to uptime for remote machines. It broadcasts on the local network, and displays the responses it receives.</p> <p>Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.</p> <p>When <i>host</i> arguments are given, rather than broadcasting rup will only query the list of specified hosts.</p> <p>A remote host will only respond if it is running the rstatd daemon, which is normally started up from inetd(1M).</p>				
OPTIONS	<p>-h Sort the display alphabetically by host name.</p> <p>-l Sort the display by load average.</p> <p>-t Sort the display by up time.</p>

rup(1C)

NAME rup – show host status of remote machines (RPC version)

SYNOPSIS **rup** [-hlt]
rup [*host...*]

DESCRIPTION rup gives a status similar to uptime for remote machines. It broadcasts on the local network, and displays the responses it receives.

Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

When *host* arguments are given, rather than broadcasting rup only queries the list of specified hosts.

A remote host will only respond if it is running the rstatd daemon, which is normally started up from inetd(1M).

OPTIONS -h Sort the display alphabetically by host name.
-l Sort the display by load average.
-t Sort the display by up time.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO ruptime(1), inetd(1M), attributes(5)

BUGS Broadcasting does not work through gateways.

NAME	ruptime – show host status of local machines				
SYNOPSIS	ruptime [-ar] [-l -t -u]				
DESCRIPTION	<p>The <code>ruptime</code> utility gives a status line like <code>uptime</code> (see <code>uptime(1)</code>) for each machine on the local network; these are formed from packets broadcast by each host on the network approximately every three minutes.</p> <p>Machines for which no status report has been received for 11 minutes are shown as being down.</p> <p>Normally, the listing is sorted by host name, but this order can be changed by specifying one of the options listed below.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Counts even those users who have been idle for an hour or more. -r Reverses the sorting order. -l -t -u These options are mutually exclusive. The use of one overrides the previous one(s). -l Sorts the display by load average. -t Sorts the display by up time. -u Sorts the display by number of users. 				
FILES	<code>/var/spool/rwho/whod.*</code> data files

rusage(1B)

NAME	rusage – print resource usage for a command																																										
SYNOPSIS	<code>/usr/ucb/rusage command</code>																																										
DESCRIPTION	The <code>rusage</code> command is similar to <code>time(1)</code> . It runs the given <i>command</i> , which must be specified; that is, <i>command</i> is not optional as it is in the C shell's timing facility. When the command is complete, <code>rusage</code> displays the real (wall clock), the system CPU, and the user CPU times which elapsed during execution of the command, plus other fields in the <code>rusage</code> structure, all on one long line. Times are reported in seconds and hundredths of a second.																																										
EXAMPLES	<p>EXAMPLE 1 The format of <code>rusage</code> output</p> <p>The example below shows the format of <code>rusage</code> output.</p> <pre>example% rusage wc /usr/share/man/man1/csh (1) 3045 13423 78071 /usr/share/man/man1/csh (1) 2.26 real 0.80 user 0.36 sys 11 pf 38 pr 0 sw 11 rb 0 wb 16 vcx 37 icx 24 mx 0 ix 1230 id 9 is example%</pre> <p>Each of the fields identified corresponds to an element of the <code>rusage</code> structure, as described in <code>getrusage(3C)</code>, as follows:</p> <table><tr><td><code>real</code></td><td></td><td>elapsed real time</td></tr><tr><td><code>user</code></td><td><code>ru_utime</code></td><td>user time used</td></tr><tr><td><code>sys</code></td><td><code>ru_stime</code></td><td>system time used</td></tr><tr><td><code>pf</code></td><td><code>ru_majflt</code></td><td>page faults requiring physical I/O</td></tr><tr><td><code>pr</code></td><td><code>ru_minflt</code></td><td>page faults not requiring physical I/O</td></tr><tr><td><code>sw</code></td><td><code>ru_nswap</code></td><td>swaps</td></tr><tr><td><code>rb</code></td><td><code>ru_inblock</code></td><td>block input operations</td></tr><tr><td><code>wb</code></td><td><code>ru_oublock</code></td><td>block output operations</td></tr><tr><td><code>vcx</code></td><td><code>ru_nvcsw</code></td><td>voluntary context switches</td></tr><tr><td><code>icx</code></td><td><code>ru_nivcsw</code></td><td>involuntary context switches</td></tr><tr><td><code>mx</code></td><td><code>ru_maxrss</code></td><td>maximum resident set size</td></tr><tr><td><code>ix</code></td><td><code>ru_ixrss</code></td><td>currently 0</td></tr><tr><td><code>id</code></td><td><code>ru_idrss</code></td><td>integral resident set size</td></tr><tr><td><code>is</code></td><td><code>ru_isrss</code></td><td>currently 0</td></tr></table>	<code>real</code>		elapsed real time	<code>user</code>	<code>ru_utime</code>	user time used	<code>sys</code>	<code>ru_stime</code>	system time used	<code>pf</code>	<code>ru_majflt</code>	page faults requiring physical I/O	<code>pr</code>	<code>ru_minflt</code>	page faults not requiring physical I/O	<code>sw</code>	<code>ru_nswap</code>	swaps	<code>rb</code>	<code>ru_inblock</code>	block input operations	<code>wb</code>	<code>ru_oublock</code>	block output operations	<code>vcx</code>	<code>ru_nvcsw</code>	voluntary context switches	<code>icx</code>	<code>ru_nivcsw</code>	involuntary context switches	<code>mx</code>	<code>ru_maxrss</code>	maximum resident set size	<code>ix</code>	<code>ru_ixrss</code>	currently 0	<code>id</code>	<code>ru_idrss</code>	integral resident set size	<code>is</code>	<code>ru_isrss</code>	currently 0

Availability	SUNWscpu

SEE ALSO csh(1), time(1), getrusage(3C), attributes(5)

BUGS When the command being timed is interrupted, the timing values displayed may be inaccurate.

rusers(1)

NAME rusers – who is logged in on remote machines

SYNOPSIS **rusers** [-ahilu] *host...*

DESCRIPTION The **rusers** command produces output similar to **who(1)**, but for remote machines. The listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

The default is to print out the names of the users logged in. When the **-l** flag is given, additional information is printed for each user:

userid hostname : terminal login_date login_time idle_time login_host

If *hostname* and *login host* are the same value, the *login_host* field is not displayed. Likewise, if *hostname* is not idle, the *idle_time* is not displayed.

A remote host will only respond if it is running the **rusersd** daemon, which may be started up from **inetd(1M)** or **listen(1M)**.

OPTIONS

- a Give a report for a machine even if no users are logged on.
- h Sort alphabetically by host name.
- i Sort by idle time.
- l Give a longer listing in the style of **who(1)**.
- u Sort by number of users.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc

SEE ALSO **who(1)**, **inetd(1M)**, **listen(1M)**, **pmadm(1M)**, **sacadm(1M)**, **attributes(5)**

NAME	rwho – who is logged in on local machines
SYNOPSIS	rwho [-a]
DESCRIPTION	<p>The rwho command produces output similar to who(1), but for all machines on your network. If no report has been received from a machine for 5 minutes, rwho assumes the machine is down, and does not report users last known to be logged into that machine.</p> <p>If a user has not typed to the system for a minute or more, rwho reports this idle time. If a user has not typed to the system for an hour or more, the user is omitted from the output of rwho unless the -a flag is given.</p>
OPTIONS	<p>-a Report all users whether or not they have typed to the system in the past hour.</p>
FILES	<code>/var/spool/rwho/whod.*</code> information about other machines
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

SEE ALSO **finger(1)**, **ruptime(1)**, **who(1)**, **in.rwhod(1M)**, **attributes(5)**

NOTES **rwho** does not work through gateways.

The directory `/var/spool/rwho` must exist on the host from which **rwho** is run.

This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

The **rwho** service daemon, **in.rwhod(1M)**, must be enabled for this command to return useful results.

sag(1)

NAME	sag – system activity graph
SYNOPSIS	sag [-e <i>time</i>] [-f <i>file</i>] [-i <i>sec</i>] [-s <i>time</i>] [-T <i>term</i>] [-x <i>spec</i>] [-y <i>spec</i>]
DESCRIPTION	<p>The <i>sag</i> utility graphically displays the system activity data stored in a binary data file by a previous <i>sar</i>(1) run. Any of the <i>sar</i> data items may be plotted singly or in combination, as cross plots or versus time. Simple arithmetic combinations of data may be specified. <i>sag</i> invokes <i>sar</i> and finds the desired data by string-matching the data column header (run <i>sar</i> to see what is available). The <i>sag</i> utility requires a graphic terminal to draw the graph, and uses <i>tplot</i>(1) to produce its output. When running Solaris 2.x and OpenWindows, perform the following steps:</p> <ol style="list-style-type: none">1. Run an "xterm" as a Tektronics terminal: <code>prompt# xterm -t</code>2. In the "xterm" window, run <i>sag</i> specifying a <i>tek</i> terminal: <code>prompt# sag -T tek options</code>
OPTIONS	<p>The following options are supported and passed through to <i>sar</i> (see <i>sar</i>(1)):</p> <p>-e <i>time</i> Select data up to <i>time</i>. Default is 18:00.</p> <p>-f <i>file</i> Use <i>file</i> as the data source for <i>sar</i>. Default is the current daily data file <code>/usr/adm/sa/sadd</code>.</p> <p>-i <i>sec</i> Select data at intervals as close as possible to <i>sec</i> seconds.</p> <p>-s <i>time</i> Select data later than <i>time</i> in the form <i>hh</i> [<i>:mm</i>]. Default is 08:00.</p> <p>-T <i>term</i> Produce output suitable for terminal <i>term</i>. See <i>tplot</i>(1) for known terminals. Default for <i>term</i> is <code>\$TERM</code>.</p> <p>-x <i>spec</i> x axis specification with <i>spec</i> in the form:</p> <p style="padding-left: 40px;"><i>name</i> [<i>op name</i>] . . . [<i>lo hi</i>]</p> <p style="padding-left: 40px;"><i>name</i> is either a string that will match a column header in the <i>sar</i> report, with an optional device name in square brackets, for example, <code>r+w/s [disk-1]</code>, or an integer value. <i>op</i> is + - * or / surrounded by blank spaces. Up to five names may be specified. Parentheses are not recognized. Contrary to custom, + and - have precedence over * and /. Evaluation is left to right. Thus, <code>A/A+B*100</code> is evaluated as <code>(A/(A+B))*100</code>, and <code>A+B/C+D</code> is <code>(A+B)/(C+D)</code>. <i>lo</i> and <i>hi</i> are optional numeric scale limits. If unspecified, they are deduced from the data.</p> <p style="padding-left: 40px;">Enclose <i>spec</i> in double-quotes (" ") if it includes white space.</p> <p style="padding-left: 40px;">A single <i>spec</i> is permitted for the x axis. If unspecified, <i>time</i> is used.</p> <p>-y <i>spec</i> y axis specification with <i>spec</i> in the same form as for -x. Up to 5 <i>spec</i> arguments separated by a semi-colon (;) may be given for -y. The -y default is:</p> <p style="padding-left: 40px;"><code>-y"%usr0100;%usr+%sys0100;%usr+%sys+%wio0100"</code></p>

EXAMPLES **EXAMPLE 1** Examples of the sag command.

To see today's CPU utilization:

```
example$ sag
```

To see activity over 15 minutes of all disk drives:

```
example$ TS=`date +%H:%M`
example$ sar -o /tmp/tempfile 60 15
example$ TE=`date +%H:%M`
example$ sag -f /tmp/tempfile -s $TS -e $TE -y "r+w/s[dsk]"
```

FILES /usr/adm/sa/sadd daily data file for day dd

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

SEE ALSO sar(1), tplot(1), attributes(5)

sar(1)

NAME	sar – system activity reporter
SYNOPSIS	sar [-aAbcdgkmpqruvwy] [-o <i>filename</i>] <i>t</i> [<i>n</i>] sar [-aAbcdgkmpqruvwy] [-e <i>time</i>] [-f <i>filename</i>] [-i <i>sec</i>] [-s <i>time</i>]
DESCRIPTION	<p>In the first instance, <i>sar</i> samples cumulative activity counters in the operating system at <i>n</i> intervals of <i>t</i> seconds, where <i>t</i> should be 5 or greater. If <i>t</i> is specified with more than one option, all headers are printed together and the output may be difficult to read. (If the sampling interval is less than 5, the activity of <i>sar</i> itself may affect the sample.) If the -o option is specified, it saves the samples in <i>filename</i> in binary format. The default value of <i>n</i> is 1.</p> <p>In the second instance, no sampling interval is specified. <i>sar</i> extracts data from a previously recorded <i>filename</i>, either the one specified by the -f option or, by default, the standard system activity daily data file /var/adm/sa/sadd for the current day <i>dd</i>. The starting and ending times of the report can be bounded using the -e and -s arguments with <i>time</i> specified in the form <i>hh[:mm[:ss]]</i>. The -i option selects records at <i>sec</i> second intervals. Otherwise, all intervals found in the data file are reported.</p>
OPTIONS	<p>The following options modify the subsets of information reported by <i>sar</i>.</p> <p>-a Report use of file access system routines: iget/s, namei/s, dirblk/s</p> <p>-A Report all data. Equivalent to -abcdgkmpqruvwy.</p> <p>-b Report buffer activity: bread/s, bwrit/s transfers per second of data between system buffers and disk or other block devices. lread/s, lwrit/s accesses of system buffers. %rcache, %wcache cache hit ratios, that is, (1–bread/lread) as a percentage.</p> <p> pread/s, pwrit/s transfers using raw (physical) device mechanism.</p> <p>-c Report system calls: scall/s system calls of all types. sread/s, swrit/s, fork/s, exec/s specific system calls. rchar/s, wchar/s characters transferred by read and write system calls. No incoming or outgoing exec(2) and fork(2) calls are reported.</p> <p>-d Report activity for each block device (for example, disk or tape drive) with the exception of XDC disks and tape drives. When</p>

data is displayed, the device specification *dsk*- is generally used to represent a disk drive. The device specification used to represent a tape drive is machine dependent. The activity data reported is:

%busy, avque

portion of time device was busy servicing a transfer request, average number of requests outstanding during that time.

read/s, write/s, blks/s

number of read/write transfers from or to device, number of bytes transferred in 512-byte units.

await

average wait time in milliseconds.

avserv

average service time in milliseconds.

For more general system statistics, use *iostat(1M)*, *sar(1M)*, or *vmstat(1M)*.

See *System Administration Guide: Basic Administration* for naming conventions for disks.

- e *time* Select data up to *time*. Default is 18:00.
- f *filename* Use *filename* as the data source for *sar*. Default is the current daily data file */var/adm/sa/sadd*.
- g Report paging activities:
- | | |
|----------|---|
| pgout/s | page-out requests per second. |
| ppgout/s | pages paged-out per second. |
| pgfree/s | pages per second placed on the free list by the page stealing daemon. |
| pgscan/s | pages per second scanned by the page stealing daemon. |
| %ufs_ipf | the percentage of UFS inodes taken off the freelist by <i>iget</i> which had reusable pages associated with them. These pages are flushed and cannot be reclaimed by processes. Thus, this is the percentage of <i>igets</i> with page flushes. |
- i *sec* Select data at intervals as close as possible to *sec* seconds.
- k Report kernel memory allocation (KMA) activities:
- | | |
|----------------------|--|
| sml_mem, alloc, fail | information about the memory pool reserving and allocating space for small requests: the amount of memory in bytes KMA |
|----------------------|--|

sar(1)

	has for the small pool, the number of bytes allocated to satisfy requests for small amounts of memory, and the number of requests for small amounts of memory that were not satisfied (failed).
	lg_mem, alloc, fail information for the large memory pool (analogous to the information for the small memory pool).
	ovsz_alloc, fail the amount of memory allocated for oversize requests and the number of oversize requests which could not be satisfied (because oversized memory is allocated dynamically, there is not a pool).
-m	Report message and semaphore activities: msg/s, sema/s primitives per second.
-o <i>filename</i>	Save samples in file, <i>filename</i> , in binary format.
-p	Report paging activities: atc/s page faults per second that are satisfied by reclaiming a page currently in memory (attaches per second). pgin/s page-in requests per second. ppgin/s pages paged-in per second. pflt/s page faults from protection errors per second (illegal access to page) or "copy-on-writes". vflt/s address translation page faults per second (valid page not in memory). slock/s faults per second caused by software lock requests requiring physical I/O.
-q	Report average queue length while occupied, and percent of time occupied: runq-sz, %runocc run queue of processes in memory and runnable. swpq-sz, %swpocc these are no longer reported by sar.
-r	Report unused memory pages and disk blocks: freemem average pages available to user processes. freeswap disk blocks available for page swapping.

`-s time` Select data later than `time` in the form `hh[:mm]`. Default is `08:00`.

`-u` Report CPU utilization (the default):
`%usr, %sys, %wio, %idle`
 portion of time running in user mode, running in system mode, idle with some process waiting for block I/O, and otherwise idle.

`-v` Report status of process, i-node, file tables:
`proc-sz, inod-sz, file-sz, lock-sz`
 entries/size for each table, evaluated once at sampling point.
`ov`
 overflows that occur between sampling points for each table.

`-w` Report system swapping and switching activity:
`swpin/s, swpot/s, bswin/s, bswot/s`
 number of transfers and number of 512-byte units transferred for swapins and swapouts (including initial loading of some programs).
`pswch/s`
 process switches.

`-y` Report TTY device activity:
`rawch/s, canch/s, outch/s`
 input character rate, input character rate processed by canon, output character rate.
`rcvin/s, xmtin/s, mdmin/s`
 receive, transmit and modem interrupt rates.

EXAMPLES **EXAMPLE 1** Viewing system activity

To see today's CPU activity so far:

```
example% sar
```

EXAMPLE 2 Watching system activity evolve

To watch CPU activity evolve for 10 minutes and save data:

```
example% sar -o temp 60 10
```

EXAMPLE 3 Reviewing disk and tape activity

To later review disk and tape activity from that period:

```
example% sar -d -f temp
```

FILES `/var/adm/sa/sadd` daily data file, where `dd` are digits representing the day of the month

sar(1)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

System Administration Guide: Basic Administration

NOTES The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

NAME	sccs – front end for the Source Code Control System (SCCS)
SYNOPSIS	<pre> /usr/ccs/bin/sccs [-r] [-drootprefix] [-psubdir] subcommand [option...] [file...] /usr/xpg4/bin/sccs [-r] [-d rootprefix] [-p subdir] subcommand [option...] [file...] </pre>
DESCRIPTION	<p>The <code>sccs</code> command is a comprehensive, straightforward front end to the various utility programs of the Source Code Control System (SCCS).</p> <p><code>sccs</code> applies the indicated <i>subcommand</i> to the history file associated with each of the indicated files.</p> <p>The name of an SCCS history file is derived by prepending the 's.' prefix to the filename of a working copy. The <code>sccs</code> command normally expects these 's.' files to reside in an SCCS subdirectory. Thus, when you supply <code>sccs</code> with a <i>file</i> argument, it normally applies the subcommand to a file named <i>s.file</i> in the SCCS subdirectory. If <i>file</i> is a path name, <code>sccs</code> looks for the history file in the SCCS subdirectory of that file's parent directory. If <i>file</i> is a directory, however, <code>sccs</code> applies the subcommand to every <i>s.file</i> file it contains. Thus, the command:</p> <pre>example% sccs get program.c</pre> <p>would apply the <code>get</code> subcommand to a history file named <code>SCCS/s.program.c</code>, while the command:</p> <pre>example% sccs get SCCS</pre> <p>would apply it to every <i>s.file</i> in the SCCS subdirectory.</p> <p>Options for the <code>sccs</code> command itself must appear before the <i>subcommand</i> argument. Options for a given subcommand must appear after the <i>subcommand</i> argument. These options are specific to each subcommand, and are described along with the subcommands themselves (see Subcommands below).</p>
Running Setuid	The <code>sccs</code> command also includes the capability to run "setuid" to provide additional protection. However, this does not apply to subcommands such as <code>sccs-admin(1)</code> , since this would allow anyone to change the authorizations of the history file. Commands that would do so always run as the real user.
OPTIONS	The following options are supported:
<code>/usr/ccs/bin/sccs</code>	<code>-drootprefix</code>
<code>/usr/xpg4/bin/sccs</code>	<code>-d rootprefix</code> Define the root portion of the path name for SCCS history files. The default root portion is the current directory. <i>rootprefix</i> is prepended to the entire <i>file</i> argument, even if <i>file</i> is an absolute path name. <code>-d</code> overrides any directory specified by the <code>PROJECTDIR</code> environment variable (see ENVIRONMENT VARIABLES below).

scs(1)

<i>/usr/ccs/bin/scs</i>	<i>-psubdir</i>	
<i>/usr/xpg4/bin/scs</i>	<i>-p subdir</i>	Define the (sub)directory within which a history file is expected to reside. SCCS is the default. (See EXAMPLES, below).
	<i>-r</i>	Run <i>scs</i> with the real user ID, rather than set to the effective user ID.
OPERANDS	The following operands are supported:	
	<i>subcommand</i>	An SCCS utility name or the name of one of the pseudo-utilities listed in USAGE.
	<i>options</i>	An option or option-argument to be passed to <i>subcommand</i> .
	<i>operands</i>	An operand to be passed to <i>subcommand</i> .
USAGE	The usage for <i>scs</i> is described below.	
Subcommands	Many of the following <i>scs</i> subcommands invoke programs that reside in <i>/usr/ccs/bin</i> . Many of these subcommands accept additional arguments that are documented in the reference page for the utility program the subcommand invokes.	
	<i>admin</i>	Modify the flags or checksum of an SCCS history file. Refer to <i>scs-admin(1)</i> for more information about the <i>admin</i> utility. While <i>admin</i> can be used to initialize a history file, you may find that the <i>create</i> subcommand is simpler to use for this purpose.
<i>/usr/ccs/bin/scs</i>	<i>cdc -rsid [-y[comment]]</i>	
<i>/usr/xpg4/bin/scs</i>	<i>cdc -rsid -rsid [-y[comment]]</i>	Annotate (change) the delta commentary. Refer to <i>scs-cdc(1)</i> . The <i>fix</i> subcommand can be used to replace the delta, rather than merely annotating the existing commentary.
<i>/usr/ccs/bin/scs</i>	<i>-rsid</i>	
<i>/usr/xpg4/bin/scs</i>	<i>-r sid -rsid</i>	Specify the SCCS delta ID (SID) to which the change notation is to be added. The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the <i>release</i> and <i>level</i> fields, and for branch deltas, the <i>branch</i> and <i>sequence</i> fields. For instance, the SID for the initial delta is normally 1 . 1.
	<i>-y[comment]"</i>	Specify the comment with which to annotate the delta commentary. If <i>-y</i> is omitted, <i>scs</i> prompts for a comment. A null <i>comment</i> results in an empty annotation.

<code>/usr/ccs/bin/sccs</code>	<code>check [-b] [-u[<i>username</i>]]</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>check [-b] [-u [<i>username</i>] -U]</code>	Check for files currently being edited. Like <code>info</code> and <code>tell</code> , but returns an exit code, rather than producing a listing of files. <code>check</code> returns a non-zero exit status if anything is being edited.
	<code>-b</code>	Ignore branches.
<code>/usr/ccs/bin/sccs</code>	<code>-u[<i>username</i>]</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>-u [<i>username</i>] -U</code>	Check only files being edited by you. When <i>username</i> is specified, check only files being edited by that user. For <code>/usr/xpg4/bin/sccs</code> , the <code>-U</code> option is equivalent to <code>-u <current_user></code> .
	<code>clean [-b]</code>	Remove everything in the current directory that can be retrieved from an SCCS history. Does not remove files that are being edited.
	<code>-b</code>	Do not check branches to see if they are being edited. ' <code>clean -b</code> ' is dangerous when branch versions are kept in the same directory.
	<code>comb</code>	Generate scripts to combine deltas. Refer to <code>sccs-comb(1)</code> .
	<code>create</code>	Create (initialize) history files. <code>create</code> performs the following steps: <ul style="list-style-type: none"> ■ Renames the original source file to <code>,program.c</code> in the current directory. ■ Create the history file called <code>s.program.c</code> in the SCCS subdirectory. ■ Performs an '<code>sccs get</code>' on <code>program.c</code> to retrieve a read-only copy of the initial version.
	<code>deledit [-s] [-y[<i>comment</i>]]</code>	Equivalent to an ' <code>sccs delta</code> ' and then an ' <code>sccs edit</code> '. <code>deledit</code> checks in a delta, and checks the file back out again, but leaves the current working copy of the file intact.
	<code>-s</code>	Silent. Do not report delta numbers or statistics.
	<code>-y [<i>comment</i>]</code>	Supply a comment for the delta commentary. If <code>-y</code> is omitted, delta prompts for a comment. A null <i>comment</i> results in an empty comment field for the delta.
	<code>delget [-s] [-y[<i>comment</i>]]</code>	Perform an ' <code>sccs delta</code> ' and then an ' <code>sccs get</code> ' to check in a delta and retrieve read-only copies of the resulting new version. See the <code>deledit</code> subcommand for a description of <code>-s</code> and <code>-y</code> . <code>sccs</code> performs a <code>delta</code> on all the files specified in the argument list, and then a <code>get</code> on all the files. If an error occurs during the <code>delta</code> , the <code>get</code> is not performed.

scs(1)

	<code>delta [-s] [-y[comment]]</code>	Check in pending changes. Records the line-by-line changes introduced while the file was checked out. The effective user ID must be the same as the ID of the person who has the file checked out. Refer to <code>scs-delta(1)</code> . See the <code>deledit</code> subcommand for a description of <code>-s</code> and <code>-y</code> .
<code>/usr/ccs/bin/scs</code>	<code>diffs [-C] [-I] [-cdate-time] [-rsid] diff-options</code>	
<code>/usr/xpg4/bin/scs</code>	<code>diffs [-C] [-I] [-c date-time -cdate-time] [-r sid -rsid] diff-options</code>	Compare (in <code>diff (1)</code> format) the working copy of a file that is checked out for editing, with a version from the SCCS history. Use the most recent checked-in version by default. The <code>diffs</code> subcommand accepts the same options as <code>diff</code> . Any <code>-r</code> , <code>-c</code> , <code>-i</code> , <code>-x</code> , and <code>-t</code> options are passed to subcommand <code>get</code> . A <code>-C</code> option is passed to <code>diff</code> as <code>-c</code> . An <code>-I</code> option is passed to <code>diff</code> as <code>-i</code> .
<code>/usr/ccs/bin/scs</code>	<code>-cdate-time</code>	
<code>/usr/xpg4/bin/scs</code>	<code>-c date-time -cdate-time</code>	Use the most recent version checked in before the indicated date and time for comparison. <code>date-time</code> takes the form: <code>yy[mm[dd[hh[mm[ss]]]]]</code> . Omitted units default to their maximum possible values; that is <code>-c7502</code> is equivalent to <code>-c750228235959</code> .
<code>/usr/ccs/bin/scs</code>	<code>-rsid</code>	
<code>/usr/xpg4/bin/scs</code>	<code>-r sid -rsid</code>	Use the version corresponding to the indicated delta for comparison.
	<code>edit</code>	Retrieve a version of the file for editing. ' <code>scs edit</code> ' extracts a version of the file that is writable by you, and creates a <code>p.</code> file in the SCCS subdirectory as lock on the history, so that no one else can check that version in or out. ID keywords are retrieved in unexpanded form. <code>edit</code> accepts the same options as <code>get</code> , below. Refer to <code>scs-get(1)</code> for a list of ID keywords and their definitions.
	<code>enter</code>	Similar to <code>create</code> , but omits the final ' <code>scs get</code> '. This may be used if an ' <code>scs edit</code> ' is to be performed immediately after the history file is initialized.
<code>/usr/ccs/bin/scs</code>	<code>fix -rsid</code>	
<code>/usr/xpg4/bin/scs</code>	<code>fix -r sid -rsid</code>	Revise a (leaf) delta. Remove the indicated delta from the SCCS history, but leave a working copy of the current version in the directory. This is useful for incorporating trivial updates for which no audit record is needed, or for revising the delta commentary. <code>fix</code> must be followed by a <code>-r</code> option, to specify the SID of the delta to remove. The indicated delta must be the

most recent (leaf) delta in its branch. Use `fix` with caution since it does not leave an audit trail of differences (although the previous commentary is retained within the history file).

<code>/usr/ccs/bin/sccs</code>	<code>get [-ekmps] [-Gnewname] [-cdate-time] [-r[sid]]</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>get [-ekmps] [-G newname -Gnewname] [-c date-time -cdate-time] [-r sid -rsid]</code>	Retrieve a version from the SCCS history. By default, this is a read-only working copy of the most recent version; ID keywords are in expanded form. Refer to <code>sccs-get(1)</code> , which includes a list of ID keywords and their definitions.
	<code>-e</code>	Retrieve a version for editing. Same as <code>sccs edit</code> .
	<code>-G newname -Gnewname</code>	Use <code>newname</code> as the name of the retrieved version.
	<code>-k</code>	Retrieve a writable copy but do not check out the file. ID keywords are unexpanded.
	<code>-m</code>	Precede each line with the SID of the delta in which it was added.
	<code>-p</code>	Produce the retrieved version on the standard output. Reports that would normally go to the standard output (delta IDs and statistics) are directed to the standard error.
	<code>-s</code>	Silent. Do not report version numbers or statistics.
<code>/usr/ccs/bin/sccs</code>	<code>-cdate-time</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>-c date-time -cdate-time</code>	Retrieve the latest version checked in prior to the date and time indicated by the <code>date-time</code> argument. <code>date-time</code> takes the form: <code>yy[mm[dd[hh[mm[ss]]]]]</code> .
<code>/usr/ccs/bin/sccs</code>	<code>-r[sid]</code>	Retrieve the version corresponding to the indicated SID. If no <code>sid</code> is specified, the latest <code>sid</code> for the specified file is retrieved.
<code>/usr/xpg4/bin/sccs</code>	<code>-r sid -rsid</code>	Retrieve the version corresponding to the indicated SID.
	<code>help</code>	
	<code>message-code sccs-command</code>	
	<code>help stuck</code>	Supply more information about SCCS diagnostics. <code>help</code> displays a brief explanation of the error when you supply the code displayed by an SCCS diagnostic message. If you supply the name of an SCCS command, it prints a usage line. <code>help</code> also recognizes the keyword <code>stuck</code> . Refer to <code>sccs-help(1)</code> .

sccs(1)

/usr/ccs/bin/sccs	<code>info [-b] [-u[username]]</code>	
/usr/xpg4/bin/sccs	<code>info [-b] [-u [username] -U]</code>	Display a list of files being edited, including the version number checked out, the version to be checked in, the name of the user who holds the lock, and the date and time the file was checked out.
	<code>-b</code>	Ignore branches.
/usr/ccs/bin/sccs	<code>-u[username]</code>	
/usr/xpg4/bin/sccs	<code>-u [username] -U</code>	List only files checked out by you. When <i>username</i> is specified, list only files checked out by that user. For <code>/usr/xpg4/bin/sccs</code> , the <code>-U</code> option is equivalent to <code>-u <current_user></code> .
	<code>print</code>	Print the entire history of each named file. Equivalent to an <code>'sccs prs -e'</code> followed by an <code>'sccs get -p -m'</code> .
/usr/ccs/bin/sccs	<code>prs [-el] [-cdate-time] [-rsid]</code>	
/usr/xpg4/bin/sccs	<code>prs [-el] [-c date-time -cdate-time] [-r sid -r sid]</code>	Peruse (display) the delta table, or other portion of an <i>s</i> . file. Refer to <code>sccs-prs(1)</code> .
	<code>-e</code>	Display delta table information for all deltas earlier than the one specified with <code>-r</code> (or all deltas if none is specified).
	<code>-l</code>	Display information for all deltas later than, and including, that specified by <code>-c</code> or <code>-r</code> .
/usr/ccs/bin/sccs	<code>-cdate-time</code>	
/usr/xpg4/bin/sccs	<code>-c date-time -cdate-time</code>	Specify the latest delta checked in before the indicated date and time. The <i>date-time</i> argument takes the form: <code>yy[mm[dd[hh[mm[ss]]]]]</code> .
/usr/ccs/bin/sccs	<code>-rsid</code>	
/usr/xpg4/bin/sccs	<code>-r sid -rsid</code>	Specify a given delta by SID.
	<code>prt [-y]</code>	Display the delta table, but omit the MR field (see <code>sccsfile(4)</code> for more information on this field). Refer to <code>sccs-prt(1)</code> .
	<code>-y</code>	Display the most recent delta table entry. The format is a single output line for each file argument, which is convenient for use in a pipeline with <code>awk(1)</code> or <code>sed(1)</code> .
/usr/ccs/bin/sccs	<code>rmdel -rsid</code>	
/usr/xpg4/bin/sccs	<code>rmdel -r sid</code>	Remove the indicated delta from the history file. That delta must be the most recent (leaf) delta in its branch. Refer to <code>sccs-rmdel(1)</code> .
	<code>sact</code>	Show editing activity status of an SCCS file. Refer to <code>sccs-sact(1)</code> .

	<code>sccsdiff -rold-sid -rnew-sid diff-options</code>	Compare two versions corresponding to the indicated SIDs (deltas) using <code>diff</code> . Refer to <code>sccs-sccsdiff(1)</code> .
<code>/usr/ccs/bin/sccs</code>	<code>tell [-b] [-u[username]]</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>tell [-b] [-u [username] -U]</code>	Display the list of files that are currently checked out, one file per line.
	<code>-b</code>	Ignore branches.
<code>/usr/ccs/bin/sccs</code>	<code>-u[username]</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>-u [username] -U</code>	List only files checked out to you. When <i>username</i> is specified, list only files checked out to that user. For <code>/usr/xpg4/bin/sccs</code> , the <code>-U</code> option is equivalent to <code>-u <current_user></code> .
	<code>unedit</code>	“Undo” the last edit or ‘get -e’, and return the working copy to its previous condition. <code>unedit</code> backs out all pending changes made since the file was checked out.
	<code>unget</code>	Same as <code>unedit</code> . Refer to <code>sccs-unget(1)</code> .
	<code>val</code>	Validate the history file. Refer to <code>sccs-val(1)</code> .
	<code>what</code>	Display any expanded ID keyword strings contained in a binary (object) or text file. Refer to <code>what(1)</code> for more information.

EXAMPLES **EXAMPLE 1** Checking out, editing, and checking in a file

To check out a copy of `program.c` for editing, edit it, and then check it back in:

```
example% sccs edit program.c
1.1
new delta 1.2
14 lines

example% vi program.c
your editing session

example% sccs delget program.c
comments? clarified cryptic diagnostic
1.2
3 inserted
2 deleted
12 unchanged
1.2
15 lines
```

EXAMPLE 2 Defining the root portion of the command pathname

`sccs` converts the command:

```
example% sccs -d/usr/src/include get stdio.h
```

sccs(1)

EXAMPLE 2 Defining the root portion of the command pathname (Continued)

to:

```
/usr/ccs/bin/get /usr/src/include/SCCS/s.stdio.h
```

EXAMPLE 3 Defining the resident subdirectory

The command:

```
example% sccs -pprivate get include/stdio.h
```

becomes:

```
/usr/ccs/bin/get include/private/s.stdio.h
```

EXAMPLE 4 Initializing a history file

To initialize the history file for a source file named `program.c`, make the SCCS subdirectory, and then use 'sccs create':

```
example% mkdir SCCS
example% sccs create program.c
program.c:
1.1
14 lines
```

After verifying the working copy, you can remove the backup file that starts with a comma:

```
example% diff program.c ,program.c
example% rm ,program.c
```

EXAMPLE 5 Retrieving a file from another directory

To retrieve a file from another directory into the current directory:

```
example% sccs get /usr/src/sccs/cc.c
```

OR:

```
example% sccs -p/usr/src/sccs/ get cc.c
```

EXAMPLE 6 Checking out all files

To check out all files under SCCS in the current directory:

```
example% sccs edit SCCS
```

EXAMPLE 7 Checking in all files

To check in all files currently checked out to you:

```
example% sccs delta `sccs tell -u`
```

EXAMPLE 8 Entering multiple lines of comments

If using `-y` to enter a comment, for most shells, enclose the comment in single or double quotes. In the following example, `Myfile` is checked in with a two-line comment:

```
example% sccs deleedit Myfile -y"Entering a
multi-line comment"
No id keywords (cm7)
1.2
2 inserted
0 deleted
14 unchanged
1.2
new delta 1.3
```

Displaying the SCCS history of `Myfile`:

```
example% sccs prt Myfile

SCCS/s.Myfile:

D 1.2  01/04/20  16:37:07  me 2 1    00002/00000/00014
Entering a
multi-line comment

D 1.1  01/04/15  13:23:32  me 1 0    00014/00000/00000
date and time created 01/04/15 13:23:32 by me
```

If `-y` is not used and `sccs` prompts for a comment, the newlines must be escaped using the backslash character (`\`):

```
example% sccs deleedit Myfile
comments? Entering a \
multi-line comment
No id keywords (cm7)
1.2
0 inserted
0 deleted
14 unchanged
1.2
new delta 1.3
```

**ENVIRONMENT
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sccs`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

sccs(1)

PROJECTDIR If contains an absolute path name (beginning with a slash), *sccs* searches for SCCS history files in the directory given by that variable.

If **PROJECTDIR** does not begin with a slash, it is taken as the name of a user, and *sccs* searches the *src* or *source* subdirectory of that user's home directory for history files. If such a directory is found, it is used. Otherwise, the value is used as a relative path name.

EXIT STATUS The following exit values are returned:

0 Successful completion.
 >0 An error occurred.

FILES

SCCS	SCCS subdirectory
SCCS/d. <i>file</i>	temporary file of differences
SCCS/p. <i>file</i>	lock (permissions) file for checked-out versions
SCCS/q. <i>file</i>	temporary file
SCCS/s. <i>file</i>	SCCS history file
SCCS/x. <i>file</i>	temporary copy of the s. <i>file</i>
SCCS/z. <i>file</i>	temporary lock file
/usr/ccs/bin/*	SCCS utility programs

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

NAME	sccs-admin, admin – create and administer SCCS history files				
SYNOPSIS	<code>/usr/ccs/bin/admin [-bhnz] [-a <i>username</i> <i>groupid</i>...] [-d <i>flag</i>] ...</code> <code>[-e <i>username</i> <i>groupid</i>...] [-f <i>flag</i> [<i>value</i>]] ... [-i [<i>filename</i>]]</code> <code>[-m <i>mr-list</i>] [-r<i>release</i>] [-t [<i>description-file</i>]] [-y [<i>comment</i>]] <i>s.filename</i>...</code>				
DESCRIPTION	<p>The <code>admin</code> command creates or modifies the flags and other parameters of SCCS history files. Filenames of SCCS history files begin with the ‘s.’ prefix, and are referred to as <code>s.</code> files, or “history” files.</p> <p>The named <code>s.</code> file is created if it does not exist already. Its parameters are initialized or modified according to the options you specify. Parameters not specified are given default values when the file is initialized, otherwise they remain unchanged.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>admin</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error. The use of ‘-’ as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p>				
OPTIONS	<p>The following options are supported:</p> <p><code>-a <i>username</i> <i>groupid</i></code> Adds a user name, or a numerical group ID, to the list of users who may check deltas in or out. If the list is empty, any user is allowed to do so.</p> <p><code>-b</code> Forces encoding of binary data. Files that contain ASCII NUL or other control characters, or that do not end with a NEWLINE, are recognized as binary data files. The contents of such files are stored in the history file in encoded form. See <code>uuencode(1C)</code> for details about the encoding. This option is normally used in conjunction with <code>-i</code> to force <code>admin</code> to encode initial versions not recognized as containing binary data.</p> <p><code>-d <i>flag</i></code> Deletes the indicated <code>flag</code> from the SCCS file. The <code>-d</code> option may be specified only for existing <code>s.</code> files. See <code>-f</code> for the list of recognized flags.</p> <p><code>-e <i>username</i> <i>groupid</i></code> Erases a user name or group ID from the list of users allowed to make deltas.</p> <p><code>-f <i>flag</i> [<i>value</i>]</code> Sets the indicated <code>flag</code> to the (optional) <code>value</code> specified. The following flags are recognized:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>b</code></td> <td>Enables branch deltas. When <code>b</code> is set, branches can be created using the <code>-b</code> option of the SCCS <code>get</code> command (see <code>sccs-get(1)</code>).</td> </tr> <tr> <td><code>cceil</code></td> <td>Sets a ceiling on the releases that can be checked out. <code>ceil</code> is a number less than or equal to 9999. If <code>c</code> is not set, the ceiling is 9999.</td> </tr> </table>	<code>b</code>	Enables branch deltas. When <code>b</code> is set, branches can be created using the <code>-b</code> option of the SCCS <code>get</code> command (see <code>sccs-get(1)</code>).	<code>cceil</code>	Sets a ceiling on the releases that can be checked out. <code>ceil</code> is a number less than or equal to 9999. If <code>c</code> is not set, the ceiling is 9999.
<code>b</code>	Enables branch deltas. When <code>b</code> is set, branches can be created using the <code>-b</code> option of the SCCS <code>get</code> command (see <code>sccs-get(1)</code>).				
<code>cceil</code>	Sets a ceiling on the releases that can be checked out. <code>ceil</code> is a number less than or equal to 9999. If <code>c</code> is not set, the ceiling is 9999.				

sccs-admin(1)

<i>dsid</i>	Specifies the default delta number, or SID, to be used by an SCCS <code>get</code> command.
<i>f</i> <i>floor</i>	Sets a floor on the releases that can be checked out. The floor is a number greater than 0 but less than 9999. If <i>f</i> is not set, the floor is 1.
<i>i</i>	Treats the 'No id keywords (ge6)' message issued by an SCCS <code>get</code> or <code>delta</code> command as an error rather than a warning.
<i>j</i>	Allows concurrent updates.
<i>l</i> <i>a</i> <i>l</i> <i>release</i> [, <i>release</i> ...]	Locks the indicated list of releases against deltas. If <i>a</i> is used, this flag locks out deltas to all releases. An SCCS ' <code>get -e</code> ' command fails when applied against a locked release.
<i>m</i> <i>module</i>	Supplies a value for the module name to which the <code>%M%</code> keyword is to expand. If the <i>m</i> flag is not specified, the value assigned is the name of the SCCS file with the leading <code>s.</code> removed.
<i>n</i>	Creates empty releases when releases are skipped. These null (empty) deltas serve as anchor points for branch deltas.
<i>q</i> <i>value</i>	Supplies a <i>value</i> to which the <code>%Q%</code> keyword is to expand when a read-only version is retrieved with the SCCS <code>get</code> command.
<i>s</i> <i>number</i>	Specifies how many lines of code are scanned for the SCCS keyword.
<i>t</i> <i>type</i>	Supplies a value for the module type to which the <code>%Y%</code> keyword is to expand.
<i>v</i> [<i>program</i>]	Specifies a validation <i>program</i> for the MR numbers associated with a new delta. The optional <i>program</i> specifies the name of an MR number validity checking <i>program</i> . If this flag is set when creating an SCCS file, the <code>-m</code> option must also be used, in which case the list of MRs may be empty.
<i>y</i> [<i>value</i> , [<i>value</i>]]	Specifies the SCCS keywords to be expanded. If no <i>value</i> is specified, no keywords will be expanded.
-h	Checks the structure of an existing <code>s.</code> file (see <code>sccsfile(4)</code>), and compares a newly computed check-sum with one stored in the first line of that file. <code>-h</code> inhibits writing on the file and so nullifies the effect of any other options.

-i[*filename*]

Initializes the history file with text from the indicated file. This text constitutes the initial delta, or set of checked-in changes. If *filename* is omitted, the initial text is obtained from the standard input. Omitting the **-i** option altogether creates an empty *s*.file. You can only initialize one *s*.file with text using **-i**. This option implies the **-n** option.

-m *mr-list*

Inserts the indicated Modification Request (MR) numbers into the commentary for the initial version. When specifying more than one MR number on the command line, *mr-list* takes the form of a quoted, space-separated list. A warning results if the **v** flag is not set or the MR validation fails.

-n

Creates a new SCCS history file.

-r*release*

Specifies the release for the initial delta. **-r** may be used only in conjunction with **-i**. The initial delta is inserted into release 1 if this option is omitted. The level of the initial delta is always 1. Initial deltas are named 1.1 by default.

-t [*description-file*]

Inserts descriptive text from the file *description-file*. When **-t** is used in conjunction with **-n**, or **-i** to initialize a new *s*.file, the *description-file* must be supplied. When modifying the description for an existing file: a **-t** option without a *description-file* removes the descriptive text, if any; a **-t** option with a *description-file* replaces the existing text.

-y [*comment*]

Inserts the indicated *comment* in the "Comments:" field for the initial delta. Valid only in conjunction with **-i** or **-n**. If **-y** option is omitted, a default comment line is inserted that notes the date and time the history file was created.

-z

Recomputes the file check-sum and stores it in the first line of the *s*.file. *Caution:* It is important to verify the contents of the history file (see *sccs-val*(1), and the *print* subcommand in *sccs*(1)), since using **-z** on a truly corrupted file may prevent detection of the error.

EXAMPLES **EXAMPLE 1** Preventing SCCS keyword expansion

In the following example, 10 lines of *file* will be scanned and only the *W*, *Y*, *X* keywords will be interpreted:

```
example% sccs admin -fs10 file
example% sccs admin -fyW,Y,X file
example% get file
```

ENVIRONMENT VARIABLES

See *environ*(5) for descriptions of the following environment variables that affect the execution of *alias* and *unalias*: *LANG*, *LC_ALL*, *LC_CTYPE*, *LC_MESSAGES*, and *NLS_PATH*.

sccs-admin(1)

EXIT STATUS The following exit values are returned:

0 Successful completion.
1 An error occurred.

FILES `s.*` history file
`SCCS/s.*` history file in SCCS subdirectory
`z.*` temporary lock file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot
Interface Stability	Standard

SEE ALSO `sccs(1)`, `sccs-cdc(1)`, `sccs-delta(1)`, `sccs-get(1)`, `sccs-help(1)`,
`sccs-rmdel(1)`, `sccs-val(1)`, `sccsfile(4)`, `attributes(5)`, `environ(5)`,
`standards(5)`

DIAGNOSTICS Use the `SCCS help` command for explanations (see `sccs-help(1)`).

WARNINGS The last component of all SCCS filenames must have the 's.' prefix. New SCCS files are given mode 444 (see `chmod(1)`). All writing done by `admin` is to a temporary file with an `x.` prefix, created with mode 444 for a new SCCS file, or with the same mode as an existing SCCS file. After successful execution of `admin`, the existing `s.` file is removed and replaced with the `x.` file. This ensures that changes are made to the SCCS file only when no errors have occurred.

It is recommended that directories containing SCCS files have permission mode 755, and that the `s.` files themselves have mode 444. The mode for directories allows only the owner to modify the SCCS files contained in the directories, while the mode of the `s.` files prevents all modifications except those performed using SCCS commands.

If it should be necessary to patch an SCCS file for any reason, the mode may be changed to 644 by the owner to allow use of a text editor. However, extreme care must be taken when doing this. The edited file should *always* be processed by an '`admin -h`' command to check for corruption, followed by an '`admin -z`' command to generate a proper check-sum. Another '`admin -h`' command is recommended to ensure that the resulting `s.` file is valid.

`admin` also uses a temporary lock `s.` file, starting with the 'z.' prefix, to prevent simultaneous updates to the `s.` file. See `sccs-get(1)` for further information about the 'z. file'.

NAME	sccs-cdc, cdc – change the delta commentary of an SCCS delta
SYNOPSIS	<code>/usr/ccs/bin/cdc -rsid [-mmr-list] [-y [comment]] s.filename...</code>
DESCRIPTION	<p>cdc annotates the delta commentary for the SCCS delta ID (SID) specified by the <code>-r</code> option in each named <code>s</code> . file.</p> <p>If the <code>v</code> flag is set in the <code>s</code> . file, you can also use <code>cdc</code> to update the Modification Request (MR) list.</p> <p>If you checked in the delta, or, if you own the file and directory and have write permission, you can use <code>cdc</code> to annotate the commentary.</p> <p>Rather than replacing the existing commentary, <code>cdc</code> inserts the new comment you supply, followed by a line of the form:</p> <pre>*** CHANGED *** yy/mm/dd hh/mm/ss username</pre> <p>above the existing commentary.</p> <p>If a directory is named as the <code>s.filename</code> argument, the <code>cdc</code> command applies to all <code>s</code> . files in that directory. Unreadable <code>s</code> . files produce an error; processing continues with the next file (if any). If <code>'-'</code> is given as the <code>s.filename</code> argument, each line of the standard input is taken as the name of an SCCS history file to be processed, and the <code>-m</code> and <code>-y</code> options must be used.</p>
OPTIONS	<p><code>-rsid</code> Specify the SID of the delta to change.</p> <p><code>-mmr-list</code> Specify one or more MR numbers to add or delete. When specifying more than one MR on the command line, <code>mmr-list</code> takes the form of a quoted, space-separated list. To delete an MR number, precede it with a <code>!</code> character (an empty MR list has no effect). A list of deleted MRs is placed in the comment section of the delta commentary. If <code>-m</code> is not used and the standard input is a terminal, <code>cdc</code> prompts with <code>MRs?</code> for the list (before issuing the <code>comments?</code> prompt). <code>-m</code> is only useful when the <code>v</code> flag is set in the <code>s</code> . file. If that flag has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, <code>cdc</code> terminates and the delta commentary remains unchanged.</p> <p><code>-y[comment]</code> Use <code>comment</code> as the annotation in the delta commentary. The previous comments are retained; the <code>comment</code> is added along with a notation that the commentary was changed. A null <code>comment</code> leaves the commentary unaffected. If <code>-y</code> is not specified and the standard input is a terminal, <code>cdc</code> prompts with <code>comments?</code> for the text of the notation to be added. An unescaped NEWLINE character terminates the annotation text.</p>

sccs-cdc(1)

EXAMPLES | **EXAMPLE 1** Changing the annotated commentary

The following command:

```
example% cdc -r1.6 -y"corrected commentary" s.program.c
```

produces the following annotated commentary for delta 1.6 in s.program.c:

```
D 1.6 88/07/05 23:21:07 username 9 0 00001/00000/00000
MRs:
COMMENTS:
corrected commentary
*** CHANGED *** 88/07/07 14:09:41 username
performance enhancements in main()
```

DIAGNOSTICS | Use the SCCS help command for explanations (see sccs-help(1)).

NAME sccs-comb, comb – combine SCCS deltas

SYNOPSIS `/usr/ccs/bin/comb [-os] [-csid-list] [-psid] s.filename...`

DESCRIPTION comb generates a shell script (see `sh(1)`) that you can use to reconstruct the indicated `s` files. This script is written to the standard output.

If a directory name is used in place of the `s.filename` argument, the `comb` command applies to all `s` files in that directory. Unreadable `s` files produce an error; processing continues with the next file (if any). The use of `'-'` as the `s.filename` argument indicates that the names of files are to be read from the standard input, one `s` file per line.

If no options are specified, `comb` preserves only the most recent (leaf) delta in a branch, and the minimal number of ancestors needed to preserve the history.

OPTIONS The following options are supported:

- `-o` For each `'get -e'` generated, access the reconstructed file at the release of the delta to be created. Otherwise, the reconstructed file is accessed at the most recent ancestor. The use of `-o` may decrease the size of the reconstructed `s` file. It may also alter the shape of the delta tree of the original file.
- `-s` Generate scripts to gather statistics, rather than combining deltas. When run, the shell scripts report: the file name, size (in blocks) after combining, original size (also in blocks), and the percentage size change, computed by the formula:

$$100 * (original - combined) / original$$

This option can be used to calculate the space that will be saved, before actually doing the combining.
- `-csid-list` Include the indicated list of deltas. All other deltas are omitted. `sid-list` is a comma-separated list of SCCS delta IDs (SIDs). To specify a range of deltas, use a `'-'` separator instead of a comma, between two SIDs in the list.
- `-pSID` The SID of the oldest delta to be preserved.

FILES

<code>s.COMB</code>	reconstructed SCCS file
<code>comb?????</code>	temporary file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

scs-comb(1)

SEE ALSO | *scs(1)*, *scs-admin(1)*, *scs-cdc(1)*, *scs-delta(1)*, *scs-help(1)*,
scs-prs(1), *scs-prt(1)*, *scs-rmdel(1)*, *scs-scsdiff(1)*, *what(1)*,
scsfile(4), *attributes(5)*

DIAGNOSTICS | Use the SCCS help command for explanations (see *scs-help(1)*).

BUGS | comb may rearrange the shape of the tree of deltas. It may not save any space; in fact, it is possible for the reconstructed file to actually be larger than the original.

NAME	sccs-delta, delta – make a delta to an SCCS file
SYNOPSIS	<pre> /usr/ccs/bin/delta [-dnps] [-g sid-list -gsid-list] [-m mr-list -mmr-list] [-r sid -rsid] [-y [comment]] s.filename... /usr/xpg4/bin/delta [-dnps] [-g sid-list -gsid-list] [-m mr-list -mmr-list] [-r sid -rsid] [-y [comment]] s.filename... </pre>
DESCRIPTION	<p>The <code>delta</code> utility checks in a record of the line-by-line differences made to a checked-out version of a file under SCCS control. These changes are taken from the writable working copy that was retrieved using the SCCS <code>get</code> command (see <code>sccs-get(1)</code>). This working copy does not have the <code>'s.'</code> prefix, and is also referred to as a <code>g-file</code>.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>delta</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of <code>'-'</code> as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line (requires <code>-y</code>, and in some cases, <code>-m</code>).</p> <p><code>delta</code> may issue prompts on the standard output depending upon the options specified and the flags that are set in the <code>s.</code> file (see <code>sccs-admin(1)</code>, and the <code>-m</code> and <code>-y</code> options below, for details).</p>
<code>/usr/xpg4/bin/delta</code>	The SID of the delta is not echoed to <code>stdout</code> .
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-d</code> Use command <code>diff(1)</code> instead of <code>bdiff(1)</code>. Returns exit status 2 if <code>s.filename</code> argument is not specified. <code>-n</code> Retain the edited <code>g-file</code>, which is normally removed at the completion of processing. <code>-p</code> Display line-by-line differences (in <code>diff(1)</code> format) on the standard output. <code>-s</code> Silent. Do not display warning or confirmation messages. Do not suppress error messages (which are written to standard error). <code>-g sid-list -gsid-list</code> Specify a list of deltas to omit when the file is accessed at the SCCS version ID (SID) created by this delta. <code>sid-list</code> is a comma-separated list of SIDs. To specify a range of deltas, use a <code>'-'</code> separator instead of a comma, between two SIDs in the list. <code>-m mr-list -mmr-list</code> If the SCCS file has the <code>v</code> flag set (see <code>sccs-admin(1)</code>), you must supply one or

sccs-delta(1)

		more Modification Request (MR) numbers for the new delta. When specifying more than one MR number on the command line, <i>mr-list</i> takes the form of a quoted, space-separated list. If <i>-m</i> is not used and the standard input is a terminal, <i>delta</i> prompts with <i>MRs?</i> for the list (before issuing the <i>comments?</i> prompt). If the <i>v</i> flag in the <i>s.file</i> has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, <i>delta</i> terminates without checking in the changes.
	<i>-r sid -rsid</i>	When two or more versions are checked out, specify the version to check in. This SID value can be either the SID specified on the <i>get</i> command line, or the SID of the new version to be checked in as reported by <i>get</i> . A diagnostic results if the specified SID is ambiguous, or if one is required but not supplied.
	<i>-y[comment]</i>	Supply a comment for the delta table (version log). A null comment is accepted, and produces an empty commentary in the log. If <i>-y</i> is not specified and the standard input is a terminal, <i>delta</i> prompts with ' <i>comments?</i> '. An unescaped NEWLINE terminates the comment.
ENVIRONMENT VARIABLES		See <i>environ(5)</i> for descriptions of the following environment variables that affect the execution of <i>delta</i> : <i>LANG</i> , <i>LC_ALL</i> , <i>LC_COLLATE</i> , <i>LC_CTYPE</i> , <i>LC_MESSAGES</i> , and <i>NLSPATH</i> .
EXIT STATUS		The following exit values are returned: 0 Successful completion. 1 An error occurred and the <i>-d</i> option had not been specified. 2 An error occurred, the <i>-d</i> option had been specified, and the <i>s.filename</i> argument was not specified.
FILES	<i>d.file</i>	temporary file of differences

	<i>q.file</i>	temporary file
	<i>s.file</i>	SCCS history file

x.file temporary copy of the s.file
z.file temporary file

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

/usr/ccs/bin/delta

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

/usr/xpg4/bin/delta

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4t
Interface Stability	Standard

SEE ALSO bdiff(1), diff(1), sccs-admin(1), sccs-cdc(1), sccs-get(1), sccs-help(1), sccs-prs(1), sccs-prt(1), sccs-rmdel(1), sccs-sccsdiff(1), sccs-unget(1), sccs(1), what(1), sccsfile(4), attributes(5), environ(5), standards(5)

DIAGNOSTICS Use the SCCS help command for explanations (see sccs-help(1)).

WARNINGS Lines beginning with an ASCII SOH character (binary 001) cannot be placed in the SCCS file unless the SOH is escaped. This character has special meaning to SCCS (see sccsfile(4)) and produces an error.

sccs-get(1)

NAME	sccs-get, get – retrieve a version of an SCCS file						
SYNOPSIS	<pre> /usr/ccs/bin/get [-begkmpst] [-l [p]] [-asequence] [-c date-time -cdate-time] [-Gg-file] [-i sid-list -isid-list] [-r [sid]] [-x sid-list -xsid-list] s.filename... /usr/xpg4/bin/get [-begkmpst] [-l [p]] [-asequence] [-c date-time -cdate-time] [-Gg-file] [-i sid-list -isid-list] [-r sid -rsid] [-x sid-list -xsid-list] s.filename... </pre>						
DESCRIPTION	<p>The <code>get</code> utility retrieves a working copy from the SCCS history file, according to the specified options.</p> <p>For each <i>s.filename</i> argument, <code>get</code> displays the SCCS delta ID (SID) and number of lines retrieved.</p> <p>If a directory name is used in place of the <i>s.filename</i> argument, the <code>get</code> command applies to all <i>s</i>.files in that directory. Unreadable <i>s</i>.files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one <i>s</i>.file per line.</p> <p>The retrieved file normally has the same filename base as the <i>s</i>.file, less the prefix, and is referred to as the <i>g</i>-file.</p> <p>For each file processed, <code>get</code> responds (on the standard output) with the SID being accessed, and with the number of lines retrieved from the <i>s</i>.file.</p>						
OPTIONS	<p>The following options are supported:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">-asequence</td> <td>Retrieves the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS <code>comb</code> command (see <code>scs-comb(1)</code>). For users, <code>-r</code> is an easier way to specify a version. The <code>-a</code> option supersedes the <code>-r</code> option when both are used.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">-b</td> <td>Creates a new branch. Used with the <code>-e</code> option to indicate that the new delta should have a SID in a new branch. Instead of incrementing the level for version to be checked in, <code>get</code> indicates in the <i>p</i>.file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the <code>b</code> flag is not set in the <i>s</i>.file, this option is ignored.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">-c date-time -cdate-time</td> <td>Retrieves the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form: <i>yy</i>[<i>mm</i>[<i>dd</i>[<i>hh</i>[<i>mm</i>[<i>ss</i>]]]]]]</td> </tr> </table>	-asequence	Retrieves the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS <code>comb</code> command (see <code>scs-comb(1)</code>). For users, <code>-r</code> is an easier way to specify a version. The <code>-a</code> option supersedes the <code>-r</code> option when both are used.	-b	Creates a new branch. Used with the <code>-e</code> option to indicate that the new delta should have a SID in a new branch. Instead of incrementing the level for version to be checked in, <code>get</code> indicates in the <i>p</i> .file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the <code>b</code> flag is not set in the <i>s</i> .file, this option is ignored.	-c date-time -cdate-time	Retrieves the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form: <i>yy</i> [<i>mm</i> [<i>dd</i> [<i>hh</i> [<i>mm</i> [<i>ss</i>]]]]]]
-asequence	Retrieves the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS <code>comb</code> command (see <code>scs-comb(1)</code>). For users, <code>-r</code> is an easier way to specify a version. The <code>-a</code> option supersedes the <code>-r</code> option when both are used.						
-b	Creates a new branch. Used with the <code>-e</code> option to indicate that the new delta should have a SID in a new branch. Instead of incrementing the level for version to be checked in, <code>get</code> indicates in the <i>p</i> .file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the <code>b</code> flag is not set in the <i>s</i> .file, this option is ignored.						
-c date-time -cdate-time	Retrieves the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form: <i>yy</i> [<i>mm</i> [<i>dd</i> [<i>hh</i> [<i>mm</i> [<i>ss</i>]]]]]]						

	Units omitted from the indicated date and time default to their maximum possible values; that is <code>-c7502</code> is equivalent to <code>-c750228235959</code> . Values of <i>yy</i> in the range 69–99 refer to the twentieth century. Values in the range 00–68 refer to the twenty-first century. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the <i>date-time</i> specification must be quoted.
<code>-e</code>	Retrieves a version for editing. With this option, <code>get</code> places a lock on the <code>s</code> file, so that no one else can check in changes to the version you have checked out. If the <code>j</code> flag is set in the <code>s</code> file, the lock is advisory: <code>get</code> issues a warning message. Concurrent use of <code>'get -e'</code> for different SIDs is allowed. However, <code>get</code> will not check out a version of the file if a writable version is present in the directory. All SCCS file protections stored in the <code>s</code> file, including the release ceiling, floor, and authorized user list, are honored by <code>'get -e'</code> .
<code>-g</code>	Gets the SCCS version ID, without retrieving the version itself. Used to verify the existence of a particular SID.
<code>-Gnewname</code>	Uses <i>newname</i> as the name of the retrieved version.
<code>-i sid-list -isid-list</code>	Specifies a list of deltas to include in the retrieved version. The included deltas are noted in the standard output message. <i>sid-list</i> is a comma-separated list of SIDs. To specify a range of deltas, use a <code>'-'</code> separator instead of a comma, between two SIDs in the list.
<code>-k</code>	Suppresses expansion of ID keywords. <code>-k</code> is implied by the <code>-e</code> .
<code>-l]& p]</code>	Retrieves a summary of the delta table (version log) and write it to a listing file, with the <code>'l.'</code> prefix (called <code>'l</code> file'). When <code>-lp</code> is used, write the summary onto the standard output.
<code>-m</code>	Precedes each retrieved line with the SID of the delta in which it was added to the file. The SID is separated from the line with a TAB.
<code>-n</code>	Precedes each line with the <code>%M%</code> ID keyword and a TAB. When both the <code>-m</code> and <code>-n</code> options are used, the ID keyword precedes the SID, and the line of text.
<code>-p</code>	Writes the text of the retrieved version to the standard output. All messages that normally go to the standard output are written to the standard error instead.

sccs-get(1)

	-s	Suppresses all output normally written on the standard output. However, fatal error messages (which always go to the standard error) remain unaffected.
	-t	Retrieves the most recently created (top) delta in a given release (for example: -r1).
/usr/ccs/bin/get	-r[<i>sid</i>]	Retrieves the version corresponding to the indicated SID (delta). The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the <i>release</i> and <i>level</i> fields, and for branch deltas, the <i>branch</i> and <i>sequence</i> fields. For instance, if 1.2 is the SID, 1 is the release, and 2 is the level number. If 1.2.3.4 is the SID, 3 is the branch and 4 is the sequence number. You need not specify the entire SID to retrieve a version with <i>get</i> . When you omit -r altogether, or when you omit both release and level, <i>get</i> normally retrieves the highest release and level. If the d flag is set to an SID in the s. file and you omit the SID, <i>get</i> retrieves the default version indicated by that flag. When you specify a release but omit the level, <i>get</i> retrieves the highest level in that release. If that release does not exist, <i>get</i> retrieves highest level from the next-highest existing release. Similarly with branches, if you specify a release, level and branch, <i>get</i> retrieves the highest sequence in that branch.
/usr/xpg4/bin/get	-r <i>sid</i> -r <i>sid</i>	Same as for <i>/usr/ccs/bin/get</i> except that SID is mandatory.
	-x <i>sid-list</i> -x <i>sid-list</i>	Excludes the indicated deltas from the retrieved version. The excluded deltas are noted in the standard output message. <i>sid-list</i> is a comma-separated list of SIDs. To specify a range of deltas, use a '-' separator instead of a comma, between two SIDs in the list.
/usr/ccs/bin/get	The output format for <i>/usr/ccs/bin/get</i> is as follows: "%s\n%d lines\n", <SID>, <number of lines>	
/usr/xpg4/bin/get	The output format for <i>/usr/xpg4/bin/get</i> is as follows: "%s\n%d\n", <SID>, <number of lines>	
USAGE	Usage guidelines are as follows:	

ID Keywords In the absence of `-e` or `-k`, `get` expands the following ID keywords by replacing them with the indicated values in the text of the retrieved source.

<i>Keyword</i>	<i>Value</i>
%A%	Shorthand notation for an ID line with data for what (1) : %Z%%Y% %M% %I%%Z%
%B%	SID branch component
%C%	Current line number. Intended for identifying messages output by the program such as "this shouldn't have happened" type errors. It is <i>not</i> intended to be used on every line to provide sequence numbers.
%D%	Current date: <i>yy/mm/dd</i>
%E%	Date newest applied delta was created: <i>yy/mm/dd</i>
%F%	SCCS <i>s</i> . file name
%G%	Date newest applied delta was created: <i>mm/dd/yy</i>
%H%	Current date: <i>mm/dd/yy</i>
%I%	SID of the retrieved version: %R% . %L% . %B% . %S%
%L%	SID level component
%M%	Module name: either the value of the <i>m</i> flag in the <i>s</i> . file (see <code>sccs-admin(1)</code>), or the name of the <i>s</i> . file less the prefix
%P%	Fully qualified <i>s</i> . file name
%Q%	Value of the <i>q</i> flag in the <i>s</i> . file
%R%	SID Release component
%S%	SID Sequence component
%T%	Current time: <i>hh:mm:ss</i>
%U%	Time the newest applied delta was created: <i>hh:mm:ss</i>
%W%	Shorthand notation for an ID line with data for what: %Z%%M% %I%
%Y%	Module type: value of the <i>t</i> flag in the <i>s</i> . file
%Z%	4-character string: '@(#)', recognized by what

ID String The table below explains how the SCCS identification string is determined for retrieving and creating deltas.

scs-get(1)

Determination of SCCS Identification String				
SID (1) Specified	-b Option Used (2)	Other Conditions	SID Retrieved	SID of Delta to be Created
none (3)	no	R defaults to mR	mR.mL	mR.(mL+1)
none (3)	yes	R defaults to mR	mR.mL	mR.mL.(mB+1).1
R	no	R > mR	mR.mL	R.1 (4)
R	no	R = mR	mR.mL	mR.(mL+1)
R	yes	R > mR	mR.mL	mR.mL.(mB+1).1
R	yes	R = mR	mR.mL	mR.mL.(mB+1).1
R	-	R < mR and R does <i>not</i> exist	hR.mL (5)	hR.mL.(mB+1).1
R	-	Trunk succ. (6) in release > R and R exists	R.mL	R.mL.(mB+1).1
R.L	no	No trunk succ.	R.L	R.(L+1)
R.L	yes	No trunk succ.	R.L	R.L.(mB+1).1
R.L	-	Trunk succ. in release \geq R	R.L	R.L.(mB+1).1
R.L.B	no	No branch succ.	R.L.B.mS	R.L.B.(mS+1)
R.L.B	yes	No branch succ.	R.L.B.mS	R.L.(mB+1).1
R.L.B.S	no	No branch succ.	R.L.B.S	R.L.B.(S+1)
R.L.B.S	yes	No branch succ.	R.L.B.S	R.L.(mB+1).1
R.L.B.S	-	Branch succ.	R.L.B.S	R.L.(mB+1).1

(1) 'R', 'L', 'B', and 'S' are the 'release', 'level', 'branch', and 'sequence' components of the SID, respectively; 'm' means 'maximum'. Thus, for example, 'R.mL' means 'the maximum level number within release R'; 'R.L.(mB+1).1' means 'the first sequence number on the *new* branch (that is, maximum branch number plus one) of level L within release R'. *Note:* If the SID specified is of the form 'R.L', 'R.L.B', or 'R.L.B.S', each of the specified components *must* exist.

(2) The -b option is effective only if the b flag is present in the file. An entry of '-' means 'irrelevant'.

- (3) This case applies if the *d* (default SID) flag is *not* present in the file. If the *d* flag *is* present in the file, the SID obtained from the *d* flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.
- (4) Forces creation of the *first* delta in a *new* release.
- (5) 'hR' is the highest *existing* release that is lower than the specified, *nonexistent*, release R.
- (6) Successor.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `get`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

FILES

- "g-file" version retrieved by `get`
- `l.file` file containing extracted delta table info
- `p.file` permissions (lock) file
- `z.file` temporary copy of `s.file`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

/usr/ccs/bin/get

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

/usr/xpg4/bin/get

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4t
Interface Stability	Standard

SEE ALSO

`sccs(1)`, `sccs-admin(1)`, `sccs-delta(1)`, `sccs-help(1)`, `sccs-prs(1)`, `sccs-prt(1)`, `sccs-sact(1)`, `sccs-unget(1)`, `what(1)`, `scsfile(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

DIAGNOSTICS

Use the `SCCS help` command for explanations (see `sccs-help(1)`).

BUGS

If the effective user has write permission (either explicitly or implicitly) in the directory containing the SCCS files, but the real user does not, only one file may be named when using `-e`.

sccs-help(1)

NAME | sccs-help, help – ask for help regarding SCCS error or warning messages

SYNOPSIS | `/usr/ccs/bin/help` [*argument...*]

DESCRIPTION | The help utility retrieves information to further explain errors messages and warnings from SCCS commands. It also provides some information about SCCS command usage. If no arguments are given, help prompts for one.

| An *argument* may be a message number (which normally appears in parentheses following each SCCS error or warning message), or an SCCS command name. help responds with an explanation of the message or a usage line for the command.

| When all else fails, try `'/usr/ccs/bin/help stuck'`.

FILES | `/usr/lib/help` directory containing files of message text

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

SEE ALSO | `sccs(1)`, `sccs-admin(1)`, `sccs-cdc(1)`, `sccs-comb(1)`, `sccs-delta(1)`, `sccs-get(1)`, `sccs-prs(1)`, `sccs-prt(1)`, `sccs-rmdel(1)`, `sccs-sact(1)`, `sccs-sccsdiff(1)`, `sccs-unget(1)`, `sccs-val(1)`, `what(1)`, `sccsfile(4)`, `attributes(5)`

NAME	sccs-prs, prs – display selected portions of an SCCS history
SYNOPSIS	<code>/usr/ccs/bin/prs [-ae1] [-cdate-time] [-ddataspec] [-rsid] s.filename...</code>
DESCRIPTION	<p>The <code>prs</code> utility displays part or all of the SCCS file (see <code>sccsfile(4)</code>) in a user supplied format.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>prs</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of <code>'-'</code> as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p>
OPTIONS	<p>In the absence of options, <code>prs</code> displays the delta table (version log). In the absence of <code>-d</code>, or <code>-l</code>, <code>prs</code> displays the entry for each delta indicated by the other options.</p> <p><code>-a</code> Includes all deltas, including those marked as removed (see <code>sccs-rmdel(1)</code>).</p> <p><code>-e</code> Requests information for all deltas created <i>earlier</i> than, and including, the delta indicated with <code>-r</code> or <code>-c</code>.</p> <p><code>-l</code> Requests information for all deltas created <i>later</i> than, and including, the delta indicated with <code>-r</code> or <code>-c</code>.</p> <p><code>-cdate-time</code> Either options <code>-e</code> or <code>-l</code> must be used with this option. <code>-cdate-time</code> displays information on the deltas checked in either prior to and including the date and time indicated by the <code>date-time</code> argument (option <code>-e</code>); or later than and including the date and time indicated (option <code>-l</code>). <code>date-time</code> takes the form:</p> <p style="margin-left: 2em;"><code>yy[mm[dd[hh[mm[ss]]]]]]</code></p> <p>Units omitted from the indicated date and time default to their maximum possible values; that is <code>-c7502</code> is equivalent to <code>-c750228235959</code>. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the <code>date-time</code> specification must be quoted. Values of <code>yy</code> in the range 69–99 refer to the twentieth century. Values in the range of 00–68 refer to the twenty-first century.</p> <p><code>-ddataspec</code> Produce a report according to the indicated data specification. <code>dataspec</code> consists of a (quoted) text string that includes embedded data keywords of the form: <code>' :key: '</code> (see Data Keywords, below). <code>prs</code> expands these keywords in the output it produces. To specify a TAB character in the output, use <code>\t</code>; to specify a NEWLINE in the output, use <code>\n</code>.</p> <p><code>-rsid</code> Specifies the SCCS delta ID (SID) of the delta for which information is desired. If no SID is specified, the most recently created delta is used.</p>

sccs-prs(1)

USAGE Usage of `prs` is described below.

Data Keywords Data keywords specify which parts of an SCCS file are to be retrieved. All parts of an SCCS file (see `sccsfile(4)`) have an associated data keyword. A data keyword may appear any number of times in a data specification argument to `-d`. These data keywords are listed in the table below:

<i>Keyword</i>	<i>Data Item</i>	<i>File Section*</i>	<i>Value</i>	<i>Format**</i>
:A:	a format for the what string:	N/A	:Z::Y: :M: :I::Z:	S
:B:	branch number	D	<i>nnnn</i>	S
:BD:	body	B	<i>text</i>	M
:BF:	branch flag	F	yes or no	S
:CB:	ceiling boundary	F	:R:	S
:C:	comments for delta	D	<i>text</i>	M
:D:	date delta created	D	:Dy:/ :Dm:/ :Dd:	S
:Dd:	day delta created	D	<i>nn</i>	S
:Dg:	deltas ignored (seq #)	D	:DS: :DS: . . .	S
:DI:	seq-no. of deltas included, excluded, ignored	D	:Dn:/ :Dx:/ :Dg:	S
:DL:	delta line statistics	D	:Li:/ :Ld:/ :Lu:	S
:Dm:	month delta created	D	<i>nn</i>	S
:Dn:	deltas included (seq #)	D	:DS: :DS: . . .	S
:DP:	predecessor delta seq-no.	D	<i>nnnn</i>	S
:Ds:	default SID	F	:I:	S
:DS:	delta sequence number	D	<i>nnnn</i>	S
:Dt:	delta information	D	:DT: :I: :D: :T: :P: :DS: :DP:	S
:DT:	delta type	D	D or R	S
:Dx:	deltas excluded (seq #)	D	:DS: . . .	S
:Dy:	year delta created	D	<i>nn</i>	S
:F:	s . file name	N/A	<i>text</i>	S
:FB:	floor boundary	F	:R:	S
:FD:	file descriptive text	C	<i>text</i>	M

<i>Keyword</i>	<i>Data Item</i>	<i>File Section*</i>	<i>Value</i>	<i>Format**</i>
:FL:	flag list	F	text	M
:GB:	gotten body	B	text	M
:I:	SCCS delta ID (SID)	D	:R: . :L: . :B: . :S:	S
:J:	joint edit flag	F	yes or no	S
:KF:	keyword error/warning flag	F	yes or no	S
:L:	level number	D	nnnn	S
:Ld:	lines deleted by delta	D	nnnnn	S
:Li:	lines inserted by delta	D	nnnnn	S
:LK:	locked releases	F	:R: . . .	S
:Lu:	lines unchanged by delta	D	nnnnn	S
:M:	module name	F	text	S
:MF:	MR validation flag	F	yes or no	S
:MP:	MR validation program	F	text	S
:MR:	MR numbers for delta	D	text	M
:ND:	null delta flag	F	yes or no	S
:Q:	user defined keyword	F	text	S
:P:	user who created delta	D	username	S
:PN:	s . file's pathname	N/A	text	S
:R:	release number	D	nnnn	S
:S:	sequence number	D	nnnn	S
:T:	time delta created	D	:Th: . :Tm: . :Ts:	S
:Th:	hour delta created	D	nn	S
:Tm:	minutes delta created	D	nn	S
:Ts:	seconds delta created	D	nn	S
:UN:	user names	U	text	M
:W:	a form of what string	N/A	:Z: . :M: \t :I:	S
:Y:	module type flag	F	text	S
:Z:	what string delimiter	N/A	@ (#)	S

*B = body, D = delta table, F = flags, U = user names

sccs-prs(1)

**S = simple format, M = multi-line format

EXAMPLES

EXAMPLE 1 Displaying delta entries

The following command:

```
example% /usr/ccs/bin/prs -e -d":I:\t:P:" program.c
```

produces:

```
1.6 username
1.5 username...
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `prs`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

FILES

`/tmp/pr?????` temporary file

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot
Interface Stability	Standard

SEE ALSO

`sccs(1)`, `sccs-cdc(1)`, `sccs-delta(1)`, `sccs-get(1)`, `sccs-help(1)`, `sccs-prt(1)`, `sccs-sact(1)`, `sccs-sccsdiff(1)`, `what(1)`, `sccsfile(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

DIAGNOSTICS

Use the `SCCS help` command for explanations (see `sccs-help(1)`).

NAME	sccs-prt, prt – display delta table information from an SCCS file
SYNOPSIS	<code>/usr/ccs/bin/prt [-abdefistu] [-cdate-time] [-rdate-time] [-ysid] s.filename...</code>
DESCRIPTION	<p>prt prints selected portions of an SCCS file. By default, it prints the delta table (version log).</p> <p>If a directory name is used in place of the <i>s.filename</i> argument, the prt command applies to all <i>s.</i> files in that directory. Unreadable <i>s.</i> files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one <i>s.</i> file per line.</p>
OPTIONS	<p>If any option other than -y, -c, or -r is supplied, the name of each file being processed (preceded by one NEWLINE and followed by two NEWLINE characters) appears above its contents.</p> <p>If none of the -u, -f, -t, or -b options are used, -d is assumed. -s, -i are mutually exclusive, as are -c and -r.</p> <ul style="list-style-type: none"> -a Display log entries for all deltas, including those marked as removed. -b Print the body of the <i>s.</i> file. -d Print delta table entries. This is the default. -e Everything. This option implies -d, -i, -u, -f, and -t. -f Print the flags of each named <i>s.</i> file. -i Print the serial numbers of included, excluded, and ignored deltas. -s Print only the first line of the delta table entries; that is, only up to the statistics. -t Print the descriptive text contained in the <i>s.</i> file. -u Print the user-names and/or numerical group IDs of users allowed to make deltas. -cdate-time Exclude delta table entries that are specified cutoff date and time. Each entry is printed as a single line, preceded by the name of the SCCS file. This format (also produced by -r, and -y) makes it easy to sort multiple delta tables in chronological order. When both -y and -c, or -y and -r are supplied, prt stops printing when the first of the two conditions is met. -rdate-time Exclude delta table entries that are newer than the specified cutoff date and time. -ysid Exclude delta table entries made prior to the SID specified. If no delta in the table has the specified SID, the entire table is printed. If no SID is specified, the most recent delta is printed.

scs-prt(1)

Output Format

The following format is used to print those portions of the `s` file that are specified by the various options.

- NEWLINE
- Type of delta (D or R)
- SPACE
- SCCS delta ID (SID)
- TAB
- Date and time of creation in the form: *yy/mm/dd hh/mm/ss*
- SPACE
- Username the delta's creator
- TAB
- Serial number of the delta
- SPACE
- Predecessor delta's serial number
- TAB
- Line-by-line change statistics in the form: *inserted/deleted/unchanged*
- NEWLINE
- List of included deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of excluded deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of modification requests (MRs), followed by a NEWLINE (only if any MR numbers were supplied).
- Lines of the delta commentary (if any), followed by a NEWLINE.

EXAMPLES

EXAMPLE 1 Examples of `prt`.

The following command:

```
example% /usr/ccs/bin/prt -y program.c
```

produces a one-line display of the delta table entry for the most recent version:

```
s.program.c: D 1.6 88/07/06 21:39:39 username 5 4  
00159/00080/00636...
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

sccs-prt(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

SEE ALSO `sccs(1)`, `sccs-cdc(1)`, `sccs-delta(1)`, `sccs-get(1)`, `sccs-help(1)`, `sccs-prs(1)`, `sccs-sact(1)`, `sccs-sccsdiff(1)`, `what(1)`, `sccsfile(4)`, `attributes(5)`

DIAGNOSTICS Use the `SCCS help` command for explanations (see `sccs-help(1)`).

sccs-rmdel(1)

NAME | sccs-rmdel, rmdel – remove a delta from an SCCS file

SYNOPSIS | `/usr/ccs/bin/rmdel -rsid s.filename...`

DESCRIPTION | The rmdel utility removes the delta specified by the SCCS delta ID (SID) supplied with -r. The delta to be removed must be the most recent (leaf) delta in its branch. In addition, the SID must *not* be that of a version checked out for editing: it must not appear in any entry of the version lock file (p . file).

| If you created the delta, or, if you own the file and directory and have write permission, you can remove it with rmdel.

| If a directory name is used in place of the *s.filename* argument, the rmdel command applies to all *s . files* in that directory. Unreadable *s . files* produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s . file* per line.

OPTIONS | The following option is supported:

| `-rsid` Remove the version corresponding to the indicated SID (delta).

ENVIRONMENT VARIABLES | See environ(5) for descriptions of the following environment variables that affect the execution of rmdel: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

FILES | p . file permissions file
 | s . file history file
 | z . file temporary copy of the s . file

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot
Interface Stability	Standard

SEE ALSO | sccs(1), sccs-admin(1), sccs-cdc(1), sccs-comb(1), sccs-delta(1), sccs-help(1), sccs-prs(1), sccs-prt(1), sccs-sccsdiff(1), sccs-unget(1), what(1), sccsfile(4), attributes(5), environ(5), standards(5)

DIAGNOSTICS | Use the SCCS help command for explanations (see sccs-help(1)).

NAME	sccs-sact, sact – show editing activity status of an SCCS file						
SYNOPSIS	<code>/usr/ccs/bin/sact s.filename...</code>						
DESCRIPTION	<p>The <code>sact</code> utility informs the user of any SCCS files that are checked out for editing.</p> <p>The output for each named file consists of five fields separated by <code>SPACE</code> characters.</p> <ul style="list-style-type: none"> ■ SID of a delta that currently exists in the SCCS file, to which changes will be made to make the new delta ■ SID for the new delta to be created ■ Username of the person who has the file checked out for editing. ■ Date that the version was checked out. ■ Time that the version was checked out. <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>sact</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of <code>'-'</code> as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p>						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>sact</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWspot</td> </tr> <tr> <td>Interface Stability</td> <td>Standard</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWspot	Interface Stability	Standard

DIAGNOSTICS	Use the SCCS <code>help</code> command for explanations (see <code>sccs-help(1)</code>).						

scs-scsdiff(1)

NAME | scs-scsdiff, scsdiff – compare two versions of an SCCS file

SYNOPSIS | `/usr/ccs/bin/scsdiff [-p] -rsid -rsid [diff-options] s.filename`

DESCRIPTION | `scsdiff` compares two versions of an SCCS file and displays the differences between the two versions. Any number of SCCS files may be specified. The options specified apply to all named `s`. files.

OPTIONS | The following options are supported:

- `-p` | Pipe output for each file through `pr(1)`.
- `-rsid` | Specify a version corresponding to the indicated SCCS delta ID (SID) for comparison. Versions are passed to `diff(1)` in the order given.
- `diff-options` | Pass options to `diff(1)`, including: `-b`, `-c`, `-e`, `-f`, `-h`, `-u`, `-C number`, `-U number`, and `-D string`.

FILES | `/tmp/get?????` temporary files

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

SEE ALSO | `diff(1)`, `scs(1)`, `scs-delta(1)`, `scs-get(1)`, `scs-help(1)`, `scs-prs(1)`, `scs-prt(1)`, `what(1)`, `scsfile(4)`, `attributes(5)`

DIAGNOSTICS | `filename: No differences` | If the two versions are the same.

Use the SCCS `help` command for explanations of other messages. See `scs-help(1)`.

NAME | `sccs-unget, unget` – undo a previous `get` of an SCCS file

SYNOPSIS | `/usr/ccs/bin/unget [-ns] [-rsid] s.filename...`

DESCRIPTION | The `unget` utility undoes the effect of a `get -e` command executed before the creation of the pending delta.

| If a directory name is used in place of the `s.filename` argument, the `unget` command applies to all `s.` files in that directory. Unreadable `s.` files produce an error; processing continues with the next file (if any). The use of `'-'` as the `s.filename` argument indicates that the names of files are to be read from the standard input, one `s.` file per line.

OPTIONS | The following options are supported:

- n Retains the retrieved version, which is otherwise removed.
- s Suppress display of the SCCS delta ID (SID).
- rsid When multiple versions are checked out, this option specifies which pending delta to abort. A diagnostic results if the specified SID is ambiguous, or if it is necessary but omitted from the command line.

ENVIRONMENT VARIABLES | See `environ(5)` for descriptions of the following environment variables that affect the execution of `unget`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot
Interface Stability	Standard

SEE ALSO | `sccs(1)`, `sccs-delta(1)`, `sccs-get(1)`, `sccs-help(1)`, `sccs-prs(1)`, `sccs-prt(1)`, `sccs-rmdel(1)`, `sccs-sact(1)`, `sccs-scsdiff(1)`, `what(1)`, `scsfile(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

DIAGNOSTICS | Use the SCCS `help` command for explanations (see `sccs-help(1)`).

scs-val(1)

NAME	scs-val, val – validate an SCCS file
SYNOPSIS	<pre> /usr/ccs/bin/val - /usr/ccs/bin/val [-s] [-m name] [-rsid] [-y type] s.filename... </pre>
DESCRIPTION	<p>The val utility determines if the specified s . files meet the characteristics specified by the indicated arguments. val can process up to 50 files on a single command line.</p> <p>val has a special argument, '-', which reads the standard input until the end-of-file condition is detected. Each line read is independently processed as if it were a command line argument list.</p> <p>val generates diagnostic messages on the standard output for each command line and file processed and also returns a single 8-bit code upon exit as described below.</p> <p>The 8-bit code returned by val is a disjunction of the possible errors, that is, it can be interpreted as a bit string where (moving from left to right) the bits set are interpreted as follows:</p> <pre> bit 0 = missing file argument bit 1 = unknown or duplicate option bit 2 = corrupted s.file bit 3 = can not open file or file not in s.file format bit 4 = the SCCS delta ID (SID) is invalid or ambiguous bit 5 = the SID does not exist bit 6 = mismatch between %Y% and -y argument bit 7 = mismatch between %M% and -m argument </pre> <p>val can process two or more files on a given command line, and in turn can process multiple command lines (when reading the standard input). In these cases, an aggregate code is returned which is the logical OR of the codes generated for each command line and file processed.</p>
OPTIONS	<p>The following options are supported:</p> <pre> -s Silent. Suppresses the normal error or warning messages. -m name Compares name with the %M% ID keyword in the s . file. -rsid Checks to see if the indicated SID is ambiguous, invalid, or absent from the s . file. -y type Compares type with the %Y% ID keyword. </pre>
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of val: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

sccs-val(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot
Interface Stability	Standard

SEE ALSO `sccs(1)`, `sccs-admin(1)`, `sccs-delta(1)`, `sccs-get(1)`, `sccs-help(1)`, `what(1)`, `sccsfile(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

DIAGNOSTICS Use the SCCS help command for explanations (see `sccs-help(1)`).

scp(1)

NAME	scp – secure copy (remote file copy program)
SYNOPSIS	scp [-pqrvc46] [-S <i>program</i>] [-P <i>port</i>] [-c <i>cipher</i>] [-i <i>identity_file</i>] [-o <i>option</i>] [[<i>user1@</i>] <i>host1</i> :] <i>file1</i> [[<i>user2@</i>] <i>host2</i> :] <i>file2</i> [...]
DESCRIPTION	<p>The <i>scp</i> utility copies files between hosts on a network. It uses <i>ssh</i>(1) for data transfer, and uses the same authentication and provides the same security as <i>ssh</i>(1). Unlike <i>rcp</i>(1), <i>scp</i> will ask for passwords or passphrases if they are needed for authentication.</p> <p>Any file name may contain a host and user specification to indicate that the file is to be copied to/from that host. Copies between two remote hosts are permitted.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-4 Forces <i>scp</i> to use IPv4 addresses only.-6 Forces <i>scp</i> to use IPv6 addresses only.-B Selects batch mode. (Prevents asking for passwords or passphrases.)-c <i>cipher</i> Selects the cipher to use for encrypting the data transfer. This option is directly passed to <i>ssh</i>(1).-C Compression enable. Passes the -C flag to <i>ssh</i>(1) to enable compression.-i <i>identity_file</i> Selects the file from which the identity (private key) for RSA authentication is read. This option is directly passed to <i>ssh</i>(1).-o <i>option</i> The given option is directly passed to <i>ssh</i>(1).-p Preserves modification times, access times, and modes from the original file.-P <i>port</i> Specifies the port to connect to on the remote host. Notice that this option is written with a capital 'P', because -p is already reserved for preserving the times and modes of the file in <i>rcp</i>(1).-q Disables the progress meter.-r Recursively copies entire directories.-S <i>program</i> Specifies the name of the program to use for the encrypted connection. The program must understand <i>ssh</i>(1) options.-v Verbose mode. Causes <i>scp</i> and <i>ssh</i>(1) to print debugging messages about their progress. This is helpful in debugging connection, authentication, and configuration problems.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"><i>host1, host2,...</i> The name(s) of the host from or to which the file is to be copied.<i>file1, file2,...</i> The file(s) to be copied.

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

AUTHORS `scp` is based on the `rcp(1)` program in the BSD source code from the Regents of the University of California. The authors are Timo Rinne and Tatu Ylonen.

script(1)

NAME | script – make record of a terminal session

SYNOPSIS | **script** [-a] [*filename*]

DESCRIPTION | *script* makes a record of everything printed on your screen. The record is written to *filename*. If no file name is given, the record is saved in the file *typescript*.

| The *script* command forks and creates a sub-shell, according to the value of \$SHELL, and records the text from this session. The script ends when the forked shell exits or when CTRL-D is typed.

OPTIONS | -a Append the session record to *filename*, rather than overwrite it.

NOTES | *script* places everything that appears on the screen in *filename*, including prompts.

ATTRIBUTES | See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

SEE ALSO | *attributes(5)*

NAME	sdiff – print differences between two files side-by-side
SYNOPSIS	sdiff [-l] [-s] [-o <i>output</i>] [-w <i>n</i>] <i>filename1 filename2</i>
DESCRIPTION	sdiff uses the output of the <code>diff</code> command to produce a side-by-side listing of two files indicating lines that are different. Lines of the two files are printed with a blank gutter between them if the lines are identical, a <code><</code> in the gutter if the line appears only in <i>filename1</i> , a <code>></code> in the gutter if the line appears only in <i>filename2</i> , and a <code> </code> for lines that are different. (See the EXAMPLES section below.)
OPTIONS	<p><code>-l</code> Print only the left side of any lines that are identical.to</p> <p><code>-s</code> Do not print identical lines.</p> <p><code>-o <i>output</i></code> Use the argument <i>output</i> as the name of a third file that is created as a user-controlled merge of <i>filename1</i> and <i>filename2</i>. Identical lines of <i>filename1</i> and <i>filename2</i> are copied to <i>output</i>. Sets of differences, as produced by <code>diff</code>, are printed; where a set of differences share a common gutter character. After printing each set of differences, <code>sdiff</code> prompts the user with a <code>%</code> and waits for one of the following user-typed commands:</p> <p><code>l</code> Append the left column to the output file.</p> <p><code>r</code> Append the right column to the output file.</p> <p><code>s</code> Turn on silent mode; do not print identical lines.</p> <p><code>v</code> Turn off silent mode.</p> <p><code>e l</code> Call the editor with the left column.</p> <p><code>e r</code> Call the editor with the right column.</p> <p><code>e b</code> Call the editor with the concatenation of left and right.</p> <p><code>e</code> Call the editor with a zero length file.</p> <p><code>q</code> Exit from the program.</p> <p>On exit from the editor, the resulting file is concatenated to the end of the <i>output</i> file.</p> <p><code>-w <i>n</i></code> Use the argument <i>n</i> as the width of the output line. The default line length is 130 characters.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>sdiff</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 An example of the <code>sdiff</code> command.</p> <p>A sample output of <code>sdiff</code> follows.</p> <pre>x y a a b <</pre>

sdiff(1)

EXAMPLE 1 An example of the `sdiff` command. (Continued)

```
c <
d      d
      > c
```

ENVIRONMENT VARIABLES

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `sdiff` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" locale determines how `sdiff` behaves.

`LC_CTYPE` Determines how `sdiff` handles characters. When `LC_CTYPE` is set to a valid value, `sdiff` can display and handle text and filenames containing valid characters for that locale.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NAME	sed – stream editor
SYNOPSIS	<pre> /usr/bin/sed [-n] script [file...] /usr/bin/sed [-n] [-e script]... [-f script_file]... [file...] /usr/xpg4/bin/sed [-n] script [file...] /usr/xpg4/bin/sed [-n] [-e script]... [-f script_file]... [file...] </pre>
DESCRIPTION	<p>The sed utility is a stream editor that reads one or more text files, makes editing changes according to a script of editing commands, and writes the results to standard output. The script is obtained from either the <i>script</i> operand string, or a combination of the option-arguments from the <i>-e script</i> and <i>-f script_file</i> options.</p> <p>The sed utility is a text editor. It cannot edit binary files or files containing ASCII NUL (\0) characters or very long lines.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <i>-e script</i> <i>script</i> is an edit command for sed. See USAGE below for more information on the format of <i>script</i>. If there is just one <i>-e</i> option and no <i>-f</i> options, the flag <i>-e</i> may be omitted. <i>-f script_file</i> Takes the script from <i>script_file</i>. <i>script_file</i> consists of editing commands, one per line. <i>-n</i> Suppresses the default output. <p>Multiple <i>-e</i> and <i>-f</i> options may be specified. All commands are added to the script in the order specified, regardless of their origin.</p>
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"> <i>file</i> A path name of a file whose contents will be read and edited. If multiple <i>file</i> operands are specified, the named files will be read in the order specified and the concatenation will be edited. If no <i>file</i> operands are specified, the standard input will be used. <i>script</i> A string to be used as the script of editing commands. The application must not present a <i>script</i> that violates the restrictions of a text file except that the final character need not be a NEWLINE character.
USAGE	<p>A script consists of editing commands, one per line, of the following form:</p> <pre>[address [, address]] command [arguments]</pre> <p>Zero or more blank characters are accepted before the first address and before <i>command</i>. Any number of semicolons are accepted before the first address.</p>

sed(1)

	<p>In normal operation, <i>sed</i> cyclically copies a line of input (less its terminating NEWLINE character) into a <i>pattern space</i> (unless there is something left after a D command), applies in sequence all commands whose <i>addresses</i> select that pattern space, and copies the resulting pattern space to the standard output (except under -n) and deletes the pattern space. Whenever the pattern space is written to standard output or a named file, <i>sed</i> will immediately follow it with a NEWLINE character.</p> <p>Some of the commands use a <i>hold space</i> to save all or part of the <i>pattern space</i> for subsequent retrieval. The <i>pattern</i> and <i>hold spaces</i> will each be able to hold at least 8192 bytes.</p>
sed Addresses	<p>An <i>address</i> is either empty, a decimal number that counts input lines cumulatively across files, a \$ that addresses the last line of input, or a context address, which consists of a <i>/regular expression/</i> as described on the <code>regexp(5)</code> manual page.</p> <p>A command line with no addresses selects every pattern space.</p> <p>A command line with one address selects each pattern space that matches the address.</p> <p>A command line with two addresses selects the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second address. Thereafter the process is repeated, looking again for the first address. (If the second address is a number less than or equal to the line number selected by the first address, only the line corresponding to the first address is selected.)</p> <p>Typically, address are separated from each other by a comma (,). They may also be separated by a semicolon (;).</p>
sed Regular Expressions	<p><i>sed</i> supports the basic regular expressions described on the <code>regexp(5)</code> manual page, with the following additions:</p> <p><code>\cREc</code> In a context address, the construction <code>\cREc</code>, where <i>c</i> is any character other than a backslash or NEWLINE character, is identical to <code>/RE/</code>. If the character designated by <i>c</i> appears following a backslash, then it is considered to be that literal character, which does not terminate the RE. For example, in the context address <code>\xabc\xdefx</code>, the second <code>x</code> stands for itself, so that the regular expression is <code>abcxdef</code>.</p> <p><code>\n</code> The escape sequence <code>\n</code> matches a NEWLINE character embedded in the pattern space. A literal NEWLINE character must not be used in the regular expression of a context address or in the substitute command.</p> <p>Editing commands can be applied only to non-selected pattern spaces by use of the negation command <code>!</code> (described below).</p>
sed Editing Commands	<p>In the following list of functions the maximum number of permissible addresses for each function is indicated.</p> <p>The <code>r</code> and <code>w</code> commands take an optional <i>rfile</i> (or <i>wfile</i>) parameter, separated from the command letter by one or more blank characters.</p>

Multiple commands can be specified by separating them with a semicolon (;) on the same command line.

The *text* argument consists of one or more lines, all but the last of which end with \ to hide the NEWLINE. Each embedded NEWLINE character in the text must be preceded by a backslash. Other backslashes in text are removed and the following character is treated literally. Backslashes in text are treated like backslashes in the replacement string of an s command, and may be used to protect initial blanks and tabs against the stripping that is done on every script line. The *rfile* or *wfile* argument must terminate the command line and must be preceded by exactly one blank. The use of the *wfile* parameter causes that file to be initially created, if it does not exist, or will replace the contents of an existing file. There can be at most 10 distinct *wfile* arguments.

Regular expressions match entire strings, not just individual lines, but a NEWLINE character is matched by \n in a sed RE. A NEWLINE character is not allowed in an RE. Also notice that \n cannot be used to match a NEWLINE character at the end of an input line; NEWLINE characters appear in the pattern space as a result of the N editing command.

Two of the commands take a *command-list*, which is a list of sed commands separated by NEWLINE characters, as follows:

```
{ command
  command
}
```

The { can be preceded with blank characters and can be followed with white space. The *commands* can be preceded by white space. The terminating } must be preceded by a NEWLINE character and can be preceded or followed by <blank>s. The braces may be preceded or followed by <blank>s. The command may be preceded by <blank>s, but may not be followed by <blank>s.

The following table lists the functions, with the maximum number of permissible addresses.

Max Address	Command	Description
1	a \ <i>text</i>	Append by executing N command or beginning a new cycle. Place <i>text</i> on the output before reading the next input line.
2	b <i>label</i>	Branch to the : command bearing the <i>label</i> . If <i>label</i> is empty, branch to the end of the script. Labels are recognized unique up to eight characters.
2	c \ <i>text</i>	Change. Delete the pattern space. Place <i>text</i> on the output. Start the next cycle.
2	d	Delete the pattern space. Start the next cycle.

sed(1)

Max Address	Command	Description
2	D	Delete the initial segment of the pattern space through the first new-line. Start the next cycle. (See the N command below.)
2	g	Replace the contents of the pattern space by the contents of the hold space.
2	G	Append the contents of the hold space to the pattern space.
2	h	Replace the contents of the hold space by the contents of the pattern space.
2	H	Append the contents of the pattern space to the hold space.
1	i \ <i>text</i>	Insert. Place <i>text</i> on the standard output.
2	l	/usr/bin/sed: List the pattern space on the standard output in an unambiguous form. Non-printable characters are displayed in octal notation and long lines are folded.
		/usr/xpg4/bin/sed: List the pattern space on the standard output in an unambiguous form. Non-printable characters are displayed in octal notation and long lines are folded. The characters (\, \a, \b, \f, \r, \t, and \v) are written as the corresponding escape sequences. Non-printable characters not in that table will be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than nine bits, the format used for non-printable characters is implementation dependent. Long lines are folded, with the point of folding indicated by writing a backslash followed by a NEWLINE; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line is marked with a \$.
2	n	Copy the pattern space to the standard output if default output is not suppressed. Replace the pattern space with the next line of input.

Max Address	Command	Description
2	N	Append the next line of input to the pattern space with an embedded new-line. (The current line number changes.) If no next line of input is available, the N command verb shall branch to the end of the script and quit without starting a new cycle and without writing the pattern space.
2	p	Print. Copy the pattern space to the standard output.
2	P	Copy the initial segment of the pattern space through the first new-line to the standard output.
1	q	Quit. Branch to the end of the script. Do not start a new cycle.
2	r <i>rfile</i>	Read the contents of <i>rfile</i> . Place them on the output before reading the next input line. If <i>rfile</i> does not exist or cannot be read, it is treated as if it were an empty file, causing no error condition.
2	t <i>label</i>	Test. Branch to the : command bearing the <i>label</i> if any substitutions have been made since the most recent reading of an input line or execution of a t. If <i>label</i> is empty, branch to the end of the script.
2	w <i>wfile</i>	Write. Append the pattern space to <i>wfile</i> . The first occurrence of w will cause <i>wfile</i> to be cleared. Subsequent invocations of w will append. Each time the sed command is used, <i>wfile</i> is overwritten.
2	x	Exchange the contents of the pattern and hold spaces.
2	! <i>command</i>	Don't. Apply the <i>command</i> (or group, if <i>command</i> is { }) only to lines <i>not</i> selected by the address(es).
0	: <i>label</i>	This command does nothing; it bears a <i>label</i> for b and t commands to branch to.
1	=	Place the current line number on the standard output as a line.
2	{ <i>command-list</i> }	Execute <i>command-list</i> only when the pattern space is selected.
0		An empty command is ignored.
0	#	If a # appears as the first character on a line of a script file, then that entire line is treated as a comment, with one exception: if a # appears on the first line and the character after the # is an n, then the default output will be suppressed. The rest of the line after #n is also ignored. A script file must contain at least one non-comment line.

sed(1)

Max Addr	Command (Using <i>strings</i>) and Description
2	<p><i>s</i> / <i>regular expression</i> / <i>replacement</i> / <i>flags</i></p> <p>Substitute the <i>replacement</i> string for instances of the <i>regular expression</i> in the pattern space. Any character other than backslash or newline can be used instead of a slash to delimit the RE and the replacement. Within the RE and the replacement, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.</p> <p>An ampersand (&) appearing in the <i>replacement</i> will be replaced by the string matching the RE. The special meaning of & in this context can be suppressed by preceding it by backslash. The characters <i>\n</i>, where <i>n</i> is a digit, will be replaced by the text matched by the corresponding backreference expression. For each backslash (\) encountered in scanning <i>replacement</i> from beginning to end, the following character loses its special meaning (if any). It is unspecified what special meaning is given to any character other than &, \ or digits.</p> <p>A line can be split by substituting a NEWLINE character into it. The application must escape the NEWLINE character in the <i>replacement</i> by preceding it with backslash. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.</p> <p><i>flags</i> is zero or more of:</p> <p><i>n n= 1 - 512</i>. Substitute for just the <i>n</i>th occurrence of the <i>regular expression</i>.</p> <p><i>g</i> Global. Substitute for all nonoverlapping instances of the <i>regular expression</i> rather than just the first one. If both <i>g</i> and <i>n</i> are specified, the results are unspecified.</p>
	<p><i>p</i> Print the pattern space if a replacement was made.</p> <p><i>P</i> Copy the initial segment of the pattern space through the first new-line to the standard output.</p> <p><i>w wfile</i> Write. Append the pattern space to <i>wfile</i> if a replacement was made. The first occurrence of <i>w</i> will cause <i>wfile</i> to be cleared. Subsequent invocations of <i>w</i> will append. Each time the sed command is used, <i>wfile</i> is overwritten.</p>
2	<p><i>y</i> / <i>string1</i> / <i>string2</i> /</p> <p>Transform. Replace all occurrences of characters in <i>string1</i> with the corresponding characters in <i>string2</i>. <i>string1</i> and <i>string2</i> must have the same number of characters, or if any of the characters in <i>string1</i> appear more than once, the results are undefined. Any character other than backslash or NEWLINE can be used instead of slash to delimit the strings. Within <i>string1</i> and <i>string2</i>, the delimiter itself can be used as a literal character if it is preceded by a backslash. For example, <i>y/abc/ABC/</i> replaces a with A, b with B, and c with C.</p>

See `largefile(5)` for the description of the behavior of `sed` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES | **EXAMPLE 1** An example sed script

This sed script simulates the BSD `cat -s` command, squeezing excess blank lines from standard input.

```
sed -n '
# Write non-empty lines.
./ {
    p
    d
}
# Write a single empty line, then look for more empty lines.
/^$/ p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/ {
    N
    s/./
    b Empty
}
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
p
'
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sed`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.
>0 An error occurred.

ATTRIBUTES

sed(1)

SEE ALSO | awk(1), ed(1), grep(1), attributes(5), environ(5), largefile(5), regexp(5), standards(5)

NAME	sed – stream editor
SYNOPSIS	sed [-n] [-e <i>script</i>] [-f <i>sfilename</i>] [<i>filename</i>]...
DESCRIPTION	The <i>sed</i> utility copies the <i>filenames</i> (standard input default) to the standard output, edited according to a script of commands.
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -n Suppresses the default output. -e <i>script</i> <i>script</i> is an edit command for <i>sed</i>. If there is just one -e option and no -f options, the -e flag may be omitted. -f <i>sfilename</i> Takes the script from <i>sfilename</i>.
sed Scripts	<p><i>sed</i> scripts consist of editing commands, one per line, of the following form:</p> <pre>[<i>address</i> [, <i>address</i>]] <i>function</i> [<i>arguments</i>]</pre> <p>In normal operation, <i>sed</i> cyclically copies a line of input into a <i>pattern space</i> (unless there is something left after a D command), sequentially applies all commands with <i>addresses</i> matching that pattern space until reaching the end of the script, copies the pattern space to the standard output (except under -n), and finally, deletes the pattern space.</p> <p>Some commands use a <i>hold space</i> to save all or part of the pattern space for subsequent retrieval.</p> <p>An <i>address</i> is either:</p> <ul style="list-style-type: none"> ■ a decimal number linecount, which is cumulative across input files; ■ a \$, which addresses the last input line; ■ or a context address, which is a <i>/regular expression/</i> as described on the <code>regex(5)</code> manual page, with the following exceptions: <ul style="list-style-type: none"> <code>\?RE?</code> In a context address, the construction <code>\ ?regular expression?</code>, where ? is any character, is identical to <code>/regular expression/</code>. Note: in the context address <code>\xabc\xdefx</code>, the second x stands for itself, so that the regular expression is <code>abcxdef</code>. <code>\n</code> Matches a NEWLINE embedded in the pattern space. <code>.</code> Matches any character except the NEWLINE ending the pattern space. <p><i>null</i> A command line with no address selects every pattern space.</p> <p><i>address</i> Selects each pattern space that matches.</p> <p><i>address1</i> , <i>address2</i> Selects the inclusive range from the first pattern space matching <i>address1</i> to the first pattern space matching <i>address2</i>.</p>

sed(1B)

Selects only one line if *address1* is greater than or equal to *address2*.

Comments If the first nonwhite character in a line is a '#' (pound sign), sed treats that line as a comment, and ignores it. If, however, the first such line is of the form:

#n

sed runs as if the -n flag were specified.

Functions The maximum number of permissible addresses for each function is indicated in parentheses in the list below.

An argument denoted *text* consists of one or more lines, all but the last of which end with \ to hide the NEWLINE. Backslashes in text are treated like backslashes in the replacement string of an s command, and may be used to protect initial SPACE and TAB characters against the stripping that is done on every script line.

An argument denoted *rfilename* or *wfilename* must terminate the command line and must be preceded by exactly one SPACE. Each *wfilename* is created before processing begins. There can be at most 10 distinct *wfilename* arguments.

(1) a \
text

Append: place *text* on the output before reading the next input line.

(2) b *label*

Branch to the ':' command bearing the *label*. Branch to the end of the script if *label* is empty.

(2) c \
text

Change: delete the pattern space. With 0 or 1 address or at the end of a 2 address range, place *text* on the output. Start the next cycle.

(2) d

Delete the pattern space. Start the next cycle.

(2) D

Delete the initial segment of the pattern space through the first NEWLINE. Start the next cycle.

(2) g

Replace the contents of the pattern space by the contents of the hold space.

(2) G

Append the contents of the hold space to the pattern space.

(2) h

Replace the contents of the hold space by the contents of the pattern space.

(2) H

Append the contents of the pattern space to the hold space.

(1) i \
text

Insert: place *text* on the standard output.

(2) l	List the pattern space on the standard output in an unambiguous form. Non-printing characters are spelled in two digit ASCII and long lines are folded.
(2) n	Copy the pattern space to the standard output. Replace the pattern space with the next line of input.
(2) N	Append the next line of input to the pattern space with an embedded newline. (The current line number changes.)
(2) p	Print: copy the pattern space to the standard output.
(2) P	Copy the initial segment of the pattern space through the first NEWLINE to the standard output.
(1) q	Quit: branch to the end of the script. Do not start a new cycle.
(2) r <i>rfilename</i>	Read the contents of <i>rfilename</i> . Place them on the output before reading the next input line.
(2) s/ <i>regular expression/replacement/flags</i>	Substitute the <i>replacement</i> string for instances of the <i>regular expression</i> in the pattern space. Any character may be used instead of '/'. For a fuller description see <code>regex(5)</code> . <i>flags</i> is zero or more of:
<i>n</i>	<i>n</i> = 1 – 512. Substitute for just the <i>n</i> th occurrence of the <i>regular expression</i> .
g	Global: substitute for all nonoverlapping instances of the <i>regular expression</i> rather than just the first one.
p	Print the pattern space if a replacement was made.
w <i>wfilename</i>	Write: append the pattern space to <i>wfilename</i> if a replacement was made.
(2) t <i>label</i>	Test: branch to the ':' command bearing the <i>label</i> if any substitutions have been made since the most recent reading of an input line or execution of a t. If <i>label</i> is empty, branch to the end of the script.
(2) w <i>wfilename</i>	Write: append the pattern space to <i>wfilename</i> .
(2) x	Exchange the contents of the pattern and hold spaces.
(2) y/ <i>string1/string2/</i>	Transform: replace all occurrences of characters in <i>string1</i> with the corresponding character in <i>string2</i> . The lengths of <i>string1</i> and <i>string2</i> must be equal.
(2)! <i>function</i>	Do not: apply the <i>function</i> (or group, if <i>function</i> is '{') only to lines <i>not</i> selected by the address(es).
(0) : <i>label</i>	This command does nothing; it bears a <i>label</i> for b and t commands to branch to. Note: the maximum length of <i>label</i> is seven characters.

sed(1B)

- (1) = Place the current line number on the standard output as a line.
- (2) { Execute the following commands through a matching '}' only when the pattern space is selected. Commands are separated by ';'.
- (0) An empty command is ignored.

Large Files

See `largefile(5)` for the description of the behavior of `sed` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

DIAGNOSTICS

- Too many commands
The command list contained more than 200 commands.
- Too much command text
The command list was too big for `sed` to handle. Text in the `a`, `c`, and `i` commands, text read in by `r` commands, addresses, regular expressions and replacement strings in `s` commands, and translation tables in `y` commands all require `sed` to store data internally.
- Command line too long
A command line was longer than 4000 characters.
- Too many line numbers
More than 256 decimal number linecounts were specified as addresses in the command list.
- Too many files in `w` commands
More than 10 different files were specified in `w` commands or `w` options for `s` commands in the command list.
- Too many labels
More than 50 labels were specified in the command list.
- Unrecognized command
A command was not one of the ones recognized by `sed`.
- Extra text at end of command
A command had extra text after the end.
- Illegal line number
An address was neither a decimal number linecount, a `$`, nor a context address.
- Space missing before filename
There was no space between an `r` or `w` command, or the `w` option for a `s` command, and the filename specified for that command.
- Too many '{'s
There were more { than } in the list of commands to be executed.
- Too many '}'s
There were more } than { in the list of commands to be executed.
- No addresses allowed
A command that takes no addresses had an address specified.

Only one address allowed

A command that takes one address had two addresses specified.

"\digit" out of range

The number in a `\n` item in a regular expression or a replacement string in an `s` command was greater than 9.

Bad number

One of the endpoints in a range item in a regular expression (that is, an item of the form `{n}` or `{n,m}`) was not a number.

Range endpoint too large

One of the endpoints in a range item in a regular expression was greater than 255.

More than 2 numbers given in `\{ \}`

More than two endpoints were given in a range expression.

`}` expected after `\`

A `\` appeared in a range expression and was not followed by a `}`.

First number exceeds second in `\{ \}`

The first endpoint in a range expression was greater than the second.

Illegal or missing delimiter

The delimiter at the end of a regular expression was absent.

`\(\)` imbalance

There were more `\(` than `\)`, or more `\)` than `\(`, in a regular expression.

`[]` imbalance

There were more `[` than `]`, or more `]` than `[`, in a regular expression.

First RE may not be null

The first regular expression in an address or in a `s` command was null (empty).

Ending delimiter missing on substitution

The ending delimiter in a `s` command was absent.

Ending delimiter missing on string

The ending delimiter in a `y` command was absent.

Transform strings not the same size

The two strings in a `y` command were not the same size.

Suffix too large - 512 max

The suffix in a `s` command, specifying which occurrence of the regular expression should be replaced, was greater than 512.

Label too long

A label in a command was longer than 8 characters.

Duplicate labels

The same label was specified by more than one `:` command.

sed(1B)

File name too long

The filename specified in a `r` or `w` command, or in the `w` option for a `s` command, was longer than 1024 characters.

Output line too long

An output line was longer than 4000 characters long.

Too many appends or reads after line *n*

More than 20 `a` or `r` commands were to be executed for line *n*.

Hold space overflowed.

More than 4000 characters were to be stored in the *hold space*.

FILES

usr/ucb/sed

BSD sed

BUGS

There is a combined limit of 200 `-e` and `-f` arguments. In addition, there are various internal size limits which, in rare cases, may overflow. To overcome these limitations, either combine or break out scripts, or use a pipeline of `sed` commands.

NAME	set, unset, setenv, unsetenv, export – shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents
sh	<p>set [--aefhkntuvx <i>argument</i>] ...</p> <p>unset [<i>name</i>...]</p> <p>export [<i>name</i>...]</p>
cs	<p>set [<i>var</i> [= <i>value</i>]]</p> <p>set <i>var</i> [<i>n</i>] = <i>word</i></p> <p>unset <i>pattern</i></p> <p>setenv [<i>VAR</i> [<i>word</i>]]</p> <p>unsetenv <i>variable</i></p>
ksh	<p>set [<i>±aefhkmnopstuvx</i>] [<i>±o option</i>]... [<i>±A name</i>] [<i>arg</i>...]</p> <p>unset [-f] <i>name</i>...</p> <p>**export [<i>name</i> [=value]]...</p>
sh	<p>The set built-in command has the following options:</p> <ul style="list-style-type: none"> - - Do not change any of the flags; useful in setting \$1 to -. -a Mark variables which are modified or created for export. -e Exit immediately if a command exits with a non-zero exit status. -f Disable file name generation. -h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed). -k All keyword arguments are placed in the environment for a command, not just those that precede the command name. -n Read commands but do not execute them. -t Exit after reading and executing one command. -u Treat unset variables as an error when substituting. -v Print shell input lines as they are read. -x Print commands and their arguments as they are executed. <p>Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in \$-. The remaining <i>arguments</i> are positional parameters and are assigned, in order, to \$1, \$2, If no <i>arguments</i> are given the values of all names are printed.</p> <p>For each <i>name</i>, unset removes the corresponding variable or function value. The variables PATH, PS1, PS2, MAILCHECK, and IF cannot be unset.</p>

set(1)

With the `export` built-in, the given *names* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. Function names are *not* exported.

csh With no arguments, `set` displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the *var* argument alone, `set` assigns an empty (null) value to the variable *var*. With arguments of the form *var* = *value* `set` assigns *value* to *var*, where *value* is one of:

word A single word (or quoted string).

(*wordlist*) A space-separated list of words enclosed in parentheses.

Values are command and filename expanded before being assigned. The form `set var [n] =word` replaces the *n*'th word in a multiword value with *word*.

`unset` removes variables whose names match (filename substitution) *pattern*. All variables are removed by `'unset *'`; this has noticeably distasteful side effects.

With no arguments, `setenv` displays all environment variables. With the *VAR* argument, `setenv` sets the environment variable *VAR* to an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both *VAR* and *word* arguments specified, `setenv` sets *VAR* to *word*, which must be either a single word or a quoted string. The *PATH* variable can take multiple *word* arguments, separated by colons (see `EXAMPLES`). The most commonly used environment variables, *USER*, *TERM*, and *PATH*, are automatically imported to and exported from the `cs`h variables *user*, *term*, and *path*. Use `setenv` if you need to change these variables. In addition, the shell sets the *PWD* environment variable from the `cs`h variable *cwd* whenever the latter changes.

The environment variables *LC_CTYPE*, *LC_MESSAGES*, *LC_TIME*, *LC_COLLATE*, *LC_NUMERIC*, and *LC_MONETARY* take immediate effect when changed within the C shell. See `environ(5)` for descriptions of these environment variables.

`unsetenv` removes *variable* from the environment. As with `unset`, pattern matching is not performed.

ksh The flags for the `set` built-in have meaning as follows:

- A Array assignment. Unset the variable *name* and assign values sequentially from the list *arg*. If `+A` is used, the variable *name* is not unset first.
- a All subsequent variables that are defined are automatically exported.
- e If a command has a non-zero exit status, execute the `ERR` trap, if set, and exit. This mode is disabled while reading profiles.
- f Disables file name generation.
- h Each command becomes a tracked alias when first encountered.

- k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- n Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.
- o The following argument can be one of the following option names:
 - allexport Same as -a.
 - errexit Same as -e.
 - bgnice All background jobs are run at a lower priority. This is the default mode. `emacs` Puts you in an `emacs` style in-line editor for command entry.
 - gmacs Puts you in a `gmacs` style in-line editor for command entry.
 - ignoreeof The shell will not exit on end-of-file. The command `exit` must be used.
 - keyword Same as -k.
 - markdirs All directory names resulting from file name generation have a trailing `/` appended.
 - monitor Same as -m.
 - noclobber Prevents redirection `>` from truncating existing files. Require `>|` to truncate a file when turned on.
 - noexec Same as -n.
 - noglob Same as -f.
 - nolog Do not save function definitions in history file.
 - nounset Same as -u.
 - privileged Same as -p.
 - verbose Same as -v.
 - trackall Same as -h.
 - vi Puts you in insert mode of a `vi` style in-line editor until you hit escape character `033`. This puts you in control mode. A return sends the line.
 - viraw Each character is processed as it is typed in `vi` mode.

set(1)

xtrace Same as -x.

If no option name is supplied then the current option settings are printed.

- p Disables processing of the `$HOME/.profile` file and uses the file `/etc/suid_profile` instead of the `ENV` file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.
- s Sort the positional parameters lexicographically.
- t Exit after reading and executing one command.
- u Treat unset parameters as an error when substituting.
- v Print shell input lines as they are read.
- x Print commands and their arguments as they are executed.
- Turns off -x and -v flags and stops examining arguments for flags.
- Do not change any of the flags; useful in setting `$1` to a value beginning with -. If no arguments follow this flag then the positional parameters are unset.

Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in `$-`. Unless -A is specified, the remaining arguments are positional parameters and are assigned, in order, to `$1 $2 . . .`. If no arguments are given then the names and values of all variables are printed on the standard output.

The variables given by the list of *names* are unassigned, i.e., their values and attributes are erased. `readonly` variables cannot be unset. If the -f, flag is set, then the names refer to function names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOUT`, and `_` removes their special meaning even if they are subsequently assigned.

When using `unset`, the variables given by the list of *names* are unassigned, i.e., their values and attributes are erased. `readonly` variables cannot be unset. If the -f, flag is set, then the names refer to function names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOUT`, and `_` removes their special meaning even if they are subsequently assigned.

With the `export` built-in, the given *names* are marked for automatic export to the environment of subsequently-executed commands.

On this man page, `ksh(1)` commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.

2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ****** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

csh The following example sets the `PATH` variable to search for files in the `/bin`, `/usr/bin`, `/usr/sbin`, and `/usr/ucb/bin` directories, in that order.

```
setenv PATH "/bin:/usr/bin:/usr/sbin:usr/ucb/bin"
```

set(1F)

NAME	set, unset – set and unset local or global environment variables
SYNOPSIS	set [-l <i>variable</i> [=value]] ... set [-e <i>variable</i> [=value]] ... set [-f <i>file</i> <i>variable</i> [=value]...] ... unset -l <i>variable</i> ... unset -f <i>file</i> <i>variable</i> ...
DESCRIPTION	<p>The set command sets <i>variable</i> in the environment, or adds <i>variable=value</i> to <i>file</i>. If <i>variable</i> is not equated to a value, set expects the value to be on <i>stdin</i>. The unset command removes <i>variable</i>. Note that the FMLI predefined, read-only variables (such as ARG1), may not be set or unset.</p> <p>Note that at least one of the above options must be used for each variable being set or unset. If you set a variable with the -f<i>filename</i> option, you must thereafter include <i>filename</i> in references to that variable. For example, <code>\$(<i>file</i>) VARIABLE</code>.</p> <p>FMLI inherits the UNIX environment when invoked.</p>
OPTIONS	<p>-l Sets or unsets the specified variable in the local environment. Variables set with -l will not be inherited by processes invoked from FMLI.</p> <p>-e Sets the specified variable in the UNIX environment. Variables set with -e will be inherited by any processes started from FMLI. Note that these variables cannot be unset .</p> <p>-ffile Sets or unsets the specified variable in the global environment. The argument <i>file</i> is the name, or pathname, of a file containing lines of the form <i>variable=value</i>. <i>file</i> will be created if it does not already exist. Note that no space intervenes between -f and <i>file</i>.</p>
EXAMPLES	<p>EXAMPLE 1 A sample output of set command.</p> <p>Storing a selection made in a menu:</p> <pre>name=Selection 2 action='set -l SELECTION=2'close</pre>
NOTES	<p>Variables set to be available to the UNIX environment (those set using the -e option) can only be set for the current fmli process and the processes it calls.</p> <p>When using the -f option, unless <i>file</i> is unique to the process, other users of FMLI on the same machine will be able to expand these variables, depending on the read/write permissions on <i>file</i>.</p> <p>A variable set in one frame may be referenced or unset in any other frame. This includes local variables.</p>

setcolor(1F)

NAME setcolor – redefine or create a color

SYNOPSIS **setcolor** *color red_level green_level blue_level*

DESCRIPTION The `setcolor` command takes four arguments: *color*, which must be a string naming the color; and the arguments *red_level*, *green_level*, and *blue_level*, which must be integer values defining, respectively, the intensity of the red, green, and blue components of *color*. Intensities must be in the range of 0 to 1000. If you are redefining an existing color, you must use its current name (default color names are: black, blue, green, cyan, red, magenta, yellow, and white). `setcolor` returns the color's name string.

EXAMPLES **EXAMPLE 1** A sample output of `setcolor` command.

The following is an example of the arguments that `setcolor` takes:

```
'setcolor blue 100 24 300'
```

SEE ALSO `attributes(5)`

NAME	setfacl – modify the Access Control List (ACL) for a file or files						
SYNOPSIS	<pre>setfacl [-r] -s <i>acl_entries</i> <i>file</i> setfacl [-r] -m<i>d</i> <i>acl_entries</i> <i>file</i> setfacl [-r] -f <i>acl_filefile</i></pre>						
DESCRIPTION	<p>For each file specified, <code>setfacl</code> will either replace its entire ACL, including the default ACL on a directory, or it will add, modify, or delete one or more ACL entries, including default entries on directories.</p> <p>When the <code>setfacl</code> command is used, it may result in changes to the file permission bits. When the user ACL entry for the file owner is changed, the file owner class permission bits will be modified. When the group ACL entry for the file group class is changed, the file group class permission bits will be modified. When the other ACL entry is changed, the file other class permission bits will be modified.</p> <p>If you use the <code>chmod(1)</code> command to change the file group owner permissions on a file with ACL entries, both the file group owner permissions and the ACL mask are changed to the new permissions. Be aware that the new ACL mask permissions may change the effective permissions for additional users and groups who have ACL entries on the file.</p> <p>A directory may contain default ACL entries. If a file or directory is created in a directory that contains default ACL entries, the newly created file will have permissions generated according to the intersection of the default ACL entries and the permissions requested at creation time. The <code>umask(1)</code> will not be applied if the directory contains default ACL entries. If a default ACL is specified for a specific user (or users), the file will have a regular ACL created. Otherwise, only the mode bits will be initialized according to the intersection described above. The default ACL should be thought of as the maximum discretionary access permissions that may be granted.</p> <p><i>acl_entries</i> Syntax</p> <p>For the <code>-m</code> and <code>-s</code> options, <i>acl_entries</i> are one or more comma-separated ACL entries.</p> <p>An ACL entry consists of the following fields separated by colons:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><i>entry_type</i></td> <td>Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask).</td> </tr> <tr> <td><i>uid</i> or <i>gid</i></td> <td>User name or user identification number. Or, group name or group identification number.</td> </tr> <tr> <td><i>perms</i></td> <td>Represents the permissions that are set on <i>entry_type</i>. <i>perms</i> can be indicated by the symbolic characters <code>rwX</code> or a number (the same permissions numbers used with the <code>chmod</code> command).</td> </tr> </table> <p>The following table shows the valid ACL entries (default entries may only be specified for directories):</p>	<i>entry_type</i>	Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask).	<i>uid</i> or <i>gid</i>	User name or user identification number. Or, group name or group identification number.	<i>perms</i>	Represents the permissions that are set on <i>entry_type</i> . <i>perms</i> can be indicated by the symbolic characters <code>rwX</code> or a number (the same permissions numbers used with the <code>chmod</code> command).
<i>entry_type</i>	Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask).						
<i>uid</i> or <i>gid</i>	User name or user identification number. Or, group name or group identification number.						
<i>perms</i>	Represents the permissions that are set on <i>entry_type</i> . <i>perms</i> can be indicated by the symbolic characters <code>rwX</code> or a number (the same permissions numbers used with the <code>chmod</code> command).						

setfacl(1)

ACL Entry	Description
u[ser]::perms	File owner permissions.
g[roup]::perms	File group owner permissions.
o[ther]:perms	Permissions for users other than the file owner or members of file group owner.
m[ask]:perms	The ACL mask. The mask entry indicates the maximum permissions allowed for users (other than the owner) and for groups. The mask is a quick way to change permissions on all the users and groups.
u[ser]:uid:perms	Permissions for a specific user. For <i>uid</i> , you can specify either a user name or a numeric UID.
g[roup]:gid:perms	Permissions for a specific group. For <i>gid</i> , you can specify either a group name or a numeric GID.
d[efault]:u[ser]::perms	Default file owner permissions.
d[efault]:g[roup]::perms	Default file group owner permissions.
d[efault]:o[ther]:perms	Default permissions for users other than the file owner or members of the file group owner.
d[efault]:m[ask]:perms	Default ACL mask.
d[efault]:u[ser]:uid:perms	Default permissions for a specific user. For <i>uid</i> , you can specify either a user name or a numeric UID.
d[efault]:g[roup]:gid:perms	Default permissions for a specific group. For <i>gid</i> , you can specify either a group name or a numeric GID.

For the `-d` option, *acl_entries* are one or more comma-separated ACL entries without permissions. Note that the entries for file owner, file group owner, ACL mask, and others may not be deleted.

OPTIONS

The options have the following meaning:

- `-d acl_entries` Deletes one or more entries from the file. The entries for the file owner, the file group owner, and others may not be deleted from the ACL. Notice that deleting an entry does not necessarily have the same effect as removing all permissions from the entry.
- `-f acl_file` Sets a file's ACL with the ACL entries contained in the file named *acl_file*. The same constraints on specified entries hold as with the `-s` option. The entries are not required to be in any specific order in the file. Also, if you specify a dash '-' for *acl_file*, standard input is used to set the file's ACL.

The character "#" in *acl_file* may be used to indicate a comment. All characters, starting with the "#" until the end of the line, will be ignored. Note that if the *acl_file* has been created as the output of the `getfacl(1)` command, any effective permissions, which will follow a "#", will be ignored.

- m *acl_entries* Adds one or more new ACL entries to the file, and/or modifies one or more existing ACL entries on the file. If an entry already exists for a specified *uid* or *gid*, the specified permissions will replace the current permissions. If an entry does not exist for the specified *uid* or *gid*, an entry will be created. When using the -m option to modify a default ACL, you must specify a complete default ACL (user, group, other, mask, and any additional entries) the first time.
- r Recalculates the permissions for the ACL mask entry. The permissions specified in the ACL mask entry are ignored and replaced by the maximum permissions necessary to grant the access to all additional user, file group owner, and additional group entries in the ACL. The permissions in the additional user, file group owner, and additional group entries are left unchanged.
- s *acl_entries* Sets a file's ACL. All old ACL entries are removed and replaced with the newly specified ACL. The entries need not be in any specific order. They will be sorted by the command before being applied to the file.

Required entries:

- Exactly one `user` entry specified for the file owner.
- Exactly one `group` entry for the file group owner.
- Exactly one `other` entry specified.

If there are additional user and group entries:

- Exactly one `mask` entry specified for the ACL mask that indicates the maximum permissions allowed for users (other than the owner) and groups.
- Must not be duplicate `user` entries with the same *uid*.
- Must not be duplicate `group` entries with the same *gid*.

If *file* is a directory, the following default ACL entries may be specified:

- Exactly one `default user` entry for the file owner.
- Exactly one `default group` entry for the file group owner.
- Exactly one `default mask` entry for the ACL mask.
- Exactly one `default other` entry.

setfacl(1)

There may be additional default user entries and additional default group entries specified, but there may not be duplicate additional default user entries with the same *uid*, or duplicate default group entries with the same *gid*.

EXAMPLES **EXAMPLE 1** Adding read permission only

The following example adds one ACL entry to file *abc*, which gives user *shea* read permission only.

```
setfacl -m user:shea:r-- abc
```

EXAMPLE 2 Replacing a file's entire ACL

The following example replaces the entire ACL for the file *abc*, which gives *shea* read access, the file owner all access, the file group owner read access only, the ACL mask read/write access, and others no access.

```
setfacl -s user:shea:rxw,user::rxw,group::rw-,mask:r--,other:--- abc
```

Notice that after this command, the file permission bits are *rxwxr-----*. Even though the file group owner was set with read/write permissions, the ACL mask entry limits it to have only read permissions. The mask entry also specifies the maximum permissions available to all additional user and group ACL entries. Once again, even though the user *shea* was set with all access, the mask limits it to have only read permissions. The ACL mask entry is a quick way to limit or open access to all the user and group entries in an ACL. For example, by changing the mask entry to read/write, both the file group owner and user *shea* would be given read/write access.

EXAMPLE 3 Setting the same ACL on two files

The following example sets the same ACL on file *abc* as the file *xyz*.

```
getfacl xyz | setfacl -f - abc
```

FILES /etc/passwd password file

NAME	setpgrp – set process group ID				
SYNOPSIS	setpgrp <i>command</i> [<i>arg</i> ...]				
DESCRIPTION	If the current process is not already a session leader, the <code>setpgrp</code> utility sets the process group ID and session ID to the current process ID and does an <code>exec ()</code> of <i>command</i> and its argument(s), if any.				
OPERANDS	The following operands are supported: <i>command</i> The name of a command to be invoked. <i>arg</i> An option or argument to <i>command</i> .				
EXIT STATUS	The following exit values are returned: 1 Error executing the <code>setpgrp</code> utility or during <code>exec ()</code> of <i>command</i> . Otherwise, the exit status will be that of <i>command</i> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

sftp(1)

NAME	sftp – secure file transfer program
SYNOPSIS	sftp [-vC] [-o <i>ssh_option</i>] [<i>hostname</i> <i>user@hostname</i>]
DESCRIPTION	<p>The <code>sftp</code> utility is an interactive file transfer program with a user interface similar to <code>ftp(1)</code> that uses the <code>ssh(1)</code> command to create a secure connection to the server.</p> <p><code>sftp</code> implements the SSH File Transfer Protocol as defined in IETF draft-ietf-secsh-filexfer. There is no relationship between the protocol used by <code>sftp</code> and the FTP protocol (RFC959) provided by <code>ftp(1)</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-C Enables compression, using the -C flag in <code>ssh(1)</code>.-o <i>ssh_option</i> Specifies an option to be directly passed to <code>ssh(1)</code>.-v Raises logging level. This option is also passed to <code>ssh(1)</code>.
OPERANDS	<p>The following operands are supported:</p> <p><i>hostname</i> <i>user@hostname</i> The name of the host to which <code>sftp</code> connects and logs into.</p>
INTERACTIVE COMMANDS	<p>Once in interactive mode, <code>sftp</code> understands a set of commands similar to those of <code>ftp(1)</code>. Commands are case insensitive and pathnames may be enclosed in quotes if they contain spaces.</p> <p><code>cd path</code> Changes remote directory to <i>path</i>.</p> <p><code>lcd path</code> Changes local directory to <i>path</i>.</p> <p><code>chgrp grp path</code> Changes group of file <i>path</i> to <i>grp</i>. <i>grp</i> must be a numeric GID.</p> <p><code>chmod mode path</code> Changes permissions of file <i>path</i> to <i>mode</i>.</p> <p><code>chown own path</code> Changes owner of file <i>path</i> to <i>own</i>. <i>own</i> must be a numeric UID.</p> <p><code>help</code> Displays help text.</p> <p><code>get [flags] remote-path [local-path]</code> Retrieves the <i>remote-path</i> and stores it on the local machine. If the local path name is not specified, it is given the same name it has on the remote machine. If the -P flag is specified, then the file's full permission and access time are copied too.</p> <p><code>lls [ls-options [path]]</code> Displays local directory listing of either <i>path</i> or current directory if <i>path</i> is not specified.</p>

`mkdir path`
Creates local directory specified by *path*.

`lpwd`
Prints local working directory.

`ls [path]`
Displays remote directory listing of either *path* or current directory if *path* is not specified.

`lumask umask`
Sets local umask to *umask*.

`mkdir path`
Creates remote directory specified by *path*.

`put [flags] local-path [local-path]`
Uploads *local-path* and stores it on the remote machine. If the remote path name is not specified, it is given the same name it has on the local machine. If the `-P` flag is specified, then the file's full permission and access time are copied too.

`pwd`
Displays remote working directory.

`exit`
Quits `sftp`.

`quit`
Quits `sftp`.

`rename oldpath newpath`
Renames remote file from *oldpath* to *newpath*.

`rmdir path`
Removes remote directory specified by *path*.

`rm path`
Deletes remote file specified by *path*.

`! command`
Executes *command* in local shell.

`!`
Escapes to local shell.

`?`
Synonym for `help`.

EXIT STATUS The following exit values are returned:

0 Successful completion.
1 An error occurred.

AUTHOR Damien Miller

NAME	sh, jsh – standard and job control shell and command interpreter
SYNOPSIS	<pre> /usr/bin/sh [-acefhiknprstuvx] [argument...] /usr/xpg4/bin/sh [± abCefhikmnpstuvx] [± o option...] [-c string] [arg...] /usr/bin/jsh [-acefhiknprstuvx] [argument...] </pre>
DESCRIPTION	<p>The <code>/usr/bin/sh</code> utility is a command programming language that executes commands read from a terminal or a file.</p> <p>The <code>/usr/xpg4/bin/sh</code> utility is a standards compliant shell. This utility provides all the functionality of <code>ksh(1)</code>, except in cases discussed in <code>ksh(1)</code> where differences in behavior exist.</p> <p>The <code>jsh</code> utility is an interface to the shell that provides all of the functionality of <code>sh</code> and enables job control (see <code>Job Control</code> section below).</p> <p>Arguments to the shell are listed in the <code>Invocation</code> section below.</p>
Definitions	<p>A <i>blank</i> is a tab or a space. A <i>name</i> is a sequence of ASCII letters, digits, or underscores, beginning with a letter or an underscore. A <i>parameter</i> is a name, a digit, or any of the characters <code>*</code>, <code>@</code>, <code>#</code>, <code>?</code>, <code>-</code>, <code>\$</code>, and <code>!</code>.</p>
Commands	<p>A <i>simple-command</i> is a sequence of non-blank <i>words</i> separated by <i>blanks</i>. The first <i>word</i> specifies the name of the command to be executed. Except as specified below, the remaining <i>words</i> are passed as arguments to the invoked command. The command name is passed as argument 0 (see <code>exec(2)</code>). The <i>value</i> of a <i>simple-command</i> is its exit status if it terminates normally, or (octal) <code>200+status</code> if it terminates abnormally. See <code>signal(3HEAD)</code> for a list of status values.</p> <p>A <i>pipeline</i> is a sequence of one or more <i>commands</i> separated by <code> </code>. The standard output of each <i>command</i> but the last is connected by a <code>pipe(2)</code> to the standard input of the next <i>command</i>. Each <i>command</i> is run as a separate process. The shell waits for the last <i>command</i> to terminate. The exit status of a <i>pipeline</i> is the exit status of the last command in the <i>pipeline</i>.</p> <p>A <i>list</i> is a sequence of one or more <i>pipelines</i> separated by <code>;</code>, <code>&</code>, <code>&&</code>, or <code> </code>, and optionally terminated by <code>;</code> or <code>&</code>. Of these four symbols, <code>;</code> and <code>&</code> have equal precedence, which is lower than that of <code>&&</code> and <code> </code>. The symbols <code>&&</code> and <code> </code> also have equal precedence. A semicolon (<code>;</code>) causes sequential execution of the preceding <i>pipeline</i>, that is, the shell waits for the <i>pipeline</i> to finish before executing any commands following the semicolon. An ampersand (<code>&</code>) causes asynchronous execution of the preceding pipeline, that is, the shell does <i>not</i> wait for that pipeline to finish. The symbol <code>&&</code> (<code> </code>) causes the <i>list</i> following it to be executed only if the preceding pipeline returns a zero (non-zero) exit status. An arbitrary number of newlines may appear in a <i>list</i>, instead of semicolons, to delimit commands.</p>

sh(1)

A *command* is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last *simple-command* executed in the command.

`for name [in word ...] do list done`

Each time a `for` command is executed, *name* is set to the next *word* taken from the `in word` list. If `in word ...` is omitted, then the `for` command executes the `do list` once for each positional parameter that is set (see `Parameter Substitution` section below). Execution ends when there are no more words in the list.

`case word in [pattern [| pattern]) list ; ;] ... esac`

A `case` command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation (see `File Name Generation` section), except that a slash, a leading dot, or a dot immediately following a slash need not be matched explicitly.

`if list ; then list ; [elif list ; then list ;] ... [else list ;] fi`

The *list* following `if` is executed and, if it returns a zero exit status, the *list* following the first `then` is executed. Otherwise, the *list* following `elif` is executed and, if its value is zero, the *list* following the next `then` is executed. Failing that, the `else list` is executed. If no `else list` or `then list` is executed, then the `if` command returns a zero exit status.

`while list do list done`

A `while` command repeatedly executes the `while list` and, if the exit status of the last command in the list is zero, executes the `do list`; otherwise the loop terminates. If no commands in the `do list` are executed, then the `while` command returns a zero exit status; `until` may be used in place of `while` to negate the loop termination test.

`(list)`

Execute *list* in a sub-shell.

`{ list ; }`

list is executed in the current (that is, parent) shell. The `{` must be followed by a space.

`name () { list ; }`

Define a function which is referenced by *name*. The body of the function is the *list* of commands between `{` and `}`. The `{` must be followed by a space. Execution of functions is described below (see `Execution` section). The `{` and `}` are unnecessary if the body of the function is a *command* as defined above, under `Commands`.

The following words are only recognized as the first word of a command and when not quoted:

	<code>if then else elif fi case esac for while until do done { }</code>						
Comments Lines	A word beginning with # causes that word and all the following characters up to a newline to be ignored.						
Command Substitution	<p>The shell reads commands from the string between two grave accents (``) and the standard output from these commands may be used as all or part of a word. Trailing newlines from the standard output are removed.</p> <p>No interpretation is done on the string before the string is read, except to remove backslashes (\) used to escape other characters. Backslashes may be used to escape a grave accent (`) or another backslash (\) and are removed before the command string is read. Escaping grave accents allows nested command substitution. If the command substitution lies within a pair of double quotes (" . . . ` . . . ` . . . "), a backslash used to escape a double quote (\") will be removed; otherwise, it will be left intact.</p> <p>If a backslash is used to escape a newline character (\newline), both the backslash and the newline are removed (see the later section on Quoting). In addition, backslashes used to escape dollar signs (\\$) are removed. Since no parameter substitution is done on the command string before it is read, inserting a backslash to escape a dollar sign has no effect. Backslashes that precede characters other than \, `, ", newline, and \$ are left intact when the command string is read.</p>						
Parameter Substitution	<p>The character \$ is used to introduce substitutable <i>parameters</i>. There are two types of parameters, positional and keyword. If <i>parameter</i> is a digit, it is a positional parameter. Positional parameters may be assigned values by <code>set</code>. Keyword parameters (also known as variables) may be assigned values by writing:</p> <pre>name=value [name=value] . . .</pre> <p>Pattern-matching is not performed on <i>value</i>. There cannot be a function and a variable with the same <i>name</i>.</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>\${parameter}</code></td> <td>The value, if any, of the parameter is substituted. The braces are required only when <i>parameter</i> is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If <i>parameter</i> is * or @, all the positional parameters, starting with \$1, are substituted (separated by spaces). Parameter \$0 is set from argument zero when the shell is invoked.</td> </tr> <tr> <td style="vertical-align: top;"><code>\${parameter:-word}</code></td> <td>If <i>parameter</i> is set and is non-null, substitute its value; otherwise substitute <i>word</i>.</td> </tr> <tr> <td style="vertical-align: top;"><code>\${parameter:=word}</code></td> <td>If <i>parameter</i> is not set or is null set it to <i>word</i>; the value of the parameter is substituted. Positional parameters may not be assigned in this way.</td> </tr> </table>	<code>\${parameter}</code>	The value, if any, of the parameter is substituted. The braces are required only when <i>parameter</i> is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If <i>parameter</i> is * or @, all the positional parameters, starting with \$1, are substituted (separated by spaces). Parameter \$0 is set from argument zero when the shell is invoked.	<code>\${parameter:-word}</code>	If <i>parameter</i> is set and is non-null, substitute its value; otherwise substitute <i>word</i> .	<code>\${parameter:=word}</code>	If <i>parameter</i> is not set or is null set it to <i>word</i> ; the value of the parameter is substituted. Positional parameters may not be assigned in this way.
<code>\${parameter}</code>	The value, if any, of the parameter is substituted. The braces are required only when <i>parameter</i> is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If <i>parameter</i> is * or @, all the positional parameters, starting with \$1, are substituted (separated by spaces). Parameter \$0 is set from argument zero when the shell is invoked.						
<code>\${parameter:-word}</code>	If <i>parameter</i> is set and is non-null, substitute its value; otherwise substitute <i>word</i> .						
<code>\${parameter:=word}</code>	If <i>parameter</i> is not set or is null set it to <i>word</i> ; the value of the parameter is substituted. Positional parameters may not be assigned in this way.						

sh(1)

<code>\${parameter:?word}</code>	If <i>parameter</i> is set and is non-null, substitute its value; otherwise, print <i>word</i> and exit from the shell. If <i>word</i> is omitted, the message "parameter null or not set" is printed.
<code>\${parameter:+word}</code>	If <i>parameter</i> is set and is non-null, substitute <i>word</i> ; otherwise substitute nothing.

In the above, *word* is not evaluated unless it is to be used as the substituted string, so that, in the following example, `pwd` is executed only if `d` is not set or is null:

```
echo ${d:-`pwd`}
```

If the colon (`:`) is omitted from the above expressions, the shell only checks whether *parameter* is set or not.

The following parameters are automatically set by the shell.

<code>#</code>	The number of positional parameters in decimal.
<code>-</code>	Flags supplied to the shell on invocation or by the <code>set</code> command.
<code>?</code>	The decimal value returned by the last synchronously executed command.
<code>\$</code>	The process number of this shell.
<code>!</code>	The process number of the last background command invoked.

The following parameters are used by the shell. The parameters in this section are also referred to as environment variables.

<code>HOME</code>	The default argument (home directory) for the <code>cd</code> command, set to the user's login directory by <code>login(1)</code> from the password file (see <code>passwd(4)</code>).
<code>PATH</code>	The search path for commands (see <code>Execution</code> section below).
<code>CDPATH</code>	The search path for the <code>cd</code> command.
<code>MAIL</code>	If this parameter is set to the name of a mail file <i>and</i> the <code>MAILPATH</code> parameter is not set, the shell informs the user of the arrival of mail in the specified file.
<code>MAILCHECK</code>	This parameter specifies how often (in seconds) the shell will check for the arrival of mail in the files specified by the <code>MAILPATH</code> or <code>MAIL</code> parameters. The default value is 600 seconds (10 minutes). If set to 0, the shell will check before each prompt.
<code>MAILPATH</code>	A colon-separated list of file names. If this parameter is set, the shell informs the user of the arrival of mail in any of the specified

files. Each file name can be followed by % and a message that will be printed when the modification time changes. The default message is, you have mail.

PS1	Primary prompt string, by default “ \$ ”.
PS2	Secondary prompt string, by default “ > ”.
IFS	Internal field separators, normally space, tab, and newline (see Blank Interpretation section).
SHACCT	If this parameter is set to the name of a file writable by the user, the shell will write an accounting record in the file for each shell procedure executed.
SHELL	When the shell is invoked, it scans the environment (see Environment section below) for this name.

See `environ(5)` for descriptions of the following environment variables that affect the execution of sh: `LC_CTYPE` and `LC_MESSAGES`.

The shell gives default values to `PATH`, `PS1`, `PS2`, `MAILCHECK`, and `IFS`. Default values for `HOME` and `MAIL` are set by `login(1)`.

Blank Interpretation

After parameter and command substitution, the results of substitution are scanned for internal field separator characters (those found in `IFS`) and split into distinct arguments where such characters are found. Explicit null arguments (“ ” or ‘ ’) are retained. Implicit null arguments (those resulting from *parameters* that have no values) are removed.

Input/Output Redirection

A command’s input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a *simple-command* or may precede or follow a *command* and are *not* passed on as arguments to the invoked command. *Note:* Parameter and command substitution occurs before *word* or *digit* is used.

<code><word</code>	Use file <i>word</i> as standard input (file descriptor 0).
<code>>word</code>	Use file <i>word</i> as standard output (file descriptor 1). If the file does not exist, it is created; otherwise, it is truncated to zero length.
<code>>>word</code>	Use file <i>word</i> as standard output. If the file exists, output is appended to it by first seeking to the EOF. Otherwise, the file is created.
<code>< >word</code>	Open file <i>word</i> for reading and writing as standard input.
<code><<[-]word</code>	After parameter and command substitution is done on <i>word</i> , the shell input is read up to the first line that literally matches the resulting <i>word</i> , or to an EOF. If, however, the hyphen (–) is appended to <code><<:</code>

sh(1)

1. leading tabs are stripped from *word* before the shell input is read (but after parameter and command substitution is done on *word*);
2. leading tabs are stripped from the shell input as it is read and before each line is compared with *word*; and
3. shell input is read up to the first line that literally matches the resulting *word*, or to an EOF.

If any character of *word* is quoted (see *Quoting* section later), no additional processing is done to the shell input. If no characters of *word* are quoted:

1. parameter and command substitution occurs;
2. (escaped) `\newlines` are removed; and
3. `\` must be used to quote the characters `\`, `$`, and ```.

The resulting document becomes the standard input.

`<&digit` Use the file associated with file descriptor *digit* as standard input. Similarly for the standard output using `>&digit`.

`<&-` The standard input is closed. Similarly for the standard output using `>&-`.

If any of the above is preceded by a *digit*, the file descriptor which will be associated with the file is that specified by the *digit* (instead of the default 0 or 1). For example:

```
... 2>&1
```

associates file descriptor 2 with the file currently associated with file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates redirections left-to-right. For example:

```
... 1>xxx 2>&1
```

first associates file descriptor 1 with file *xxx*. It associates file descriptor 2 with the file associated with file descriptor 1 (that is, *xxx*). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and file descriptor 1 would be associated with file *xxx*.

Using the terminology introduced on the first page, under *Commands*, if a *command* is composed of several *simple commands*, redirection will be evaluated for the entire *command* before it is evaluated for each *simple command*. That is, the shell evaluates redirection for the entire *list*, then each *pipeline* within the *list*, then each *command* within each *pipeline*, then each *list* within each *command*.

If a command is followed by `&`, the default standard input for the command is the empty file, `/dev/null`. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

File Name Generation

Before a command is executed, each command *word* is scanned for the characters `*`, `?`, and `[`. If one of these characters appears the word is regarded as a *pattern*. The word is replaced with alphabetically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. The character `.` at the start of a file name or immediately following a `/`, as well as the character `/` itself, must be matched explicitly.

- `*` Matches any string, including the null string.
- `?` Matches any single character.
- `[...]` Matches any one of the enclosed characters. A pair of characters separated by `-` matches any character lexically between the pair, inclusive. If the first character following the opening `[` is a `!`, any character not enclosed is matched.

Notice that all quoted characters (see below) must be matched explicitly in a filename.

Quoting

The following characters have a special meaning to the shell and cause termination of a word unless quoted:

```
; & ( ) | ^ < > newline space tab
```

A character may be *quoted* (that is, made to stand for itself) by preceding it with a backslash (`\`) or inserting it between a pair of quote marks (`' '` or `" "`). During processing, the shell may quote certain characters to prevent them from taking on a special meaning. Backslashes used to quote a single character are removed from the word before the command is executed. The pair `\newline` is removed from a word before command and parameter substitution.

All characters enclosed between a pair of single quote marks (`' '`), except a single quote, are quoted by the shell. Backslash has no special meaning inside a pair of single quotes. A single quote may be quoted inside a pair of double quote marks (for example, `" ' "`), but a single quote can not be quoted inside a pair of single quotes.

Inside a pair of double quote marks (`" "`), parameter and command substitution occurs and the shell quotes the results to avoid blank interpretation and file name generation. If `$*` is within a pair of double quotes, the positional parameters are substituted and quoted, separated by quoted spaces (`"$1 $2 ..."`). However, if `$@` is within a pair of double quotes, the positional parameters are substituted and quoted, separated by unquoted spaces (`"$1" "$2" ...`). `\` quotes the characters `\`, `'`, `,` (comma), and `$`. The pair `\newline` is removed before parameter and command substitution. If a backslash precedes characters other than `\`, `'`, `,` (comma), `$`, and newline, then the backslash itself is quoted by the shell.

Prompting

When used interactively, the shell prompts with the value of `PS1` before reading a command. If at any time a newline is typed and further input is needed to complete a command, the secondary prompt (that is, the value of `PS2`) is issued.

sh(1)

Environment	<p>The <i>environment</i> (see <code>environ(5)</code>) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a parameter for each name found, giving it the corresponding value. If the user modifies the value of any of these parameters or creates new parameters, none of these affects the environment unless the <code>export</code> command is used to bind the shell's parameter to the environment (see also <code>set -a</code>). A parameter may be removed from the environment with the <code>unset</code> command. The environment seen by any executed command is thus composed of any unmodified name-value pairs originally inherited by the shell, minus any pairs removed by <code>unset</code>, plus any modifications or additions, all of which must be noted in <code>export</code> commands.</p> <p>The environment for any <i>simple-command</i> may be augmented by prefixing it with one or more assignments to parameters. Thus:</p> <pre>TERM=450 command</pre> <p>and</p> <pre>(export TERM; TERM=450; command</pre> <p>are equivalent as far as the execution of <i>command</i> is concerned if <i>command</i> is not a Special Command. If <i>command</i> is a Special Command, then</p> <pre>TERM=450 command</pre> <p>will modify the <code>TERM</code> variable in the current shell.</p> <p>If the <code>-k</code> flag is set, <i>all</i> keyword arguments are placed in the environment, even if they occur after the command name. The following example first prints <code>a=b c</code> and <code>c</code>:</p> <pre>echo a=b c a=b c set -k echo a=b c c</pre> <p>Signals The <code>INTERRUPT</code> and <code>QUIT</code> signals for an invoked command are ignored if the command is followed by <code>&</code>. Otherwise, signals have the values inherited by the shell from its parent, with the exception of signal 11 (but see also the <code>trap</code> command below).</p> <p>Execution Each time a command is executed, the command substitution, parameter substitution, blank interpretation, input/output redirection, and filename generation listed above are carried out. If the command name matches the name of a defined function, the function is executed in the shell process (note how this differs from the execution of</p>
--------------------	--

shell script files, which require a sub-shell for invocation). If the command name does not match the name of a defined function, but matches one of the `Special Commands` listed below, it is executed in the shell process.

The positional parameters `$1`, `$2`, ... are set to the arguments of the function. If the command name matches neither a `Special Command` nor the name of a defined function, a new process is created and an attempt is made to execute the command via `exec(2)`.

The shell parameter `PATH` defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is `/usr/bin`. The current directory is specified by a null path name, which can appear immediately after the equal sign, between two colon delimiters anywhere in the path list, or at the end of the path list. If the command name contains a / the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an `a.out` file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. A parenthesized command is also executed in a sub-shell.

The location in the search path where a command was found is remembered by the shell (to help avoid unnecessary `execs` later). If the command was found in a relative directory, its location must be re-determined whenever the current directory changes. The shell forgets all remembered locations whenever the `PATH` variable is changed or the `hash -r` command is executed (see below).

Special Commands

Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional `Special Commands` are added to the shell's environment (see `Job Control` section below).

:

No effect; the command does nothing. A zero exit code is returned.

. *filename*

Read and execute commands from *filename* and return. The search path specified by `PATH` is used to find the directory containing *filename*.

`bg [%jobid ...]`

When Job Control is enabled, the `bg` command is added to the user's environment to manipulate jobs. Resumes the execution of a stopped job in the background. If `%jobid` is omitted the current job is assumed. (See `Job Control` section below for more detail.)

`break [n]`

Exit from the enclosing `for` or `while` loop, if any. If `n` is specified, break `n` levels.

`cd [argument]`

Change the current directory to *argument*. The shell parameter `HOME` is the default *argument*. The shell parameter `CDPATH` defines the search path for the directory containing *argument*. Alternative directory names are separated by a colon (:). The default path is `<null>` (specifying the current directory). *Note:* The current directory is specified by a null path name, which can appear immediately after the

sh(1)

equal sign or between the colon delimiters anywhere else in the path list. If *argument* begins with a / the search path is not used. Otherwise, each directory in the path is searched for *argument*.

chdir [*dir*]

chdir changes the shell's working directory to directory *dir*. If no argument is given, change to the home directory of the user. If *dir* is a relative pathname not found in the current directory, check for it in those directories listed in the CDPATH variable. If *dir* is the name of a shell variable whose value starts with a /, change to the directory named by that value.

continue [*n*]

Resume the next iteration of the enclosing **for** or **while** loop. If *n* is specified, resume at the *n*-th enclosing loop.

echo [*arguments* ...]

The words in *arguments* are written to the shell's standard output, separated by space characters. See **echo(1)** for fuller usage and description.

eval [*argument* ...]

The arguments are read as input to the shell and the resulting command(s) executed.

exec [*argument* ...]

The command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.

exit [*n*]

Causes the calling shell or shell script to exit with the exit status specified by *n*. If *n* is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)

export [*name* ...]

The given *names* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. (Variable names exported from a parent shell are listed only if they have been exported again during the current shell's execution.) Function names are *not* exported.

fg [%*jobid* ...]

When Job Control is enabled, the **fg** command is added to the user's environment to manipulate jobs. This command resumes the execution of a stopped job in the foreground and also moves an executing background job into the foreground. If %*jobid* is omitted, the current job is assumed. (See **Job Control** section below for more detail.)

getopts

Use in shell scripts to support command syntax standards (see **intro(1)**). This command parses positional parameters and checks for legal options. See **getoptcvt(1)** for usage and description.

hash [-r] [*name* ...]

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The -r option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

jobs [-p | -l] [%*jobid* ...]

jobs -x *command* [*arguments*]

Reports all jobs that are stopped or executing in the background. If *jobid* is omitted, all jobs that are stopped or running in the background will be reported. (See Job Control section below for more detail.)

kill [-sig] %*job* ...

kill -l

Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in signal(3HEAD) stripped of the prefix "SIG" with the exception that SIGCHD is named CHLD). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See Job Control section below for a description of the format of *job*. In the second form, kill -l, the signal numbers and names are listed. (See kill(1)).

login [*argument* ...]

Equivalent to 'exec login *argument* ...'. See login(1) for usage and description.

newgrp [*argument*]

Equivalent to exec newgrp *argument*. See newgrp(1) for usage and description.

pwd

Print the current working directory. See pwd(1) for usage and description.

read *name* ...

One line is read from the standard input and, using the internal field separator, IFS (normally space or tab), to delimit word boundaries, the first word is assigned to the first *name*, the second word to the second *name*, and so forth, with leftover words assigned to the last *name*. Lines can be continued using \newline. Characters other than newline can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to *names*, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an EOF is encountered.

sh(1)

`readonly [name ...]`

The given *names* are marked `readonly` and the values of these *names* may not be changed by subsequent assignment. If no arguments are given, a list of all `readonly` names is printed.

`return [n]`

Causes a function to exit with the return value specified by *n*. If *n* is omitted, the return status is that of the last command executed.

`set [-aefhkntuvx [argument ...]]`

- a Mark variables which are modified or created for export.
- e Exit immediately if a command exits with a non-zero exit status.
- f Disable file name generation.
- h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).
- k All keyword arguments are placed in the environment for a command, not just those that precede the command name.
- n Read commands but do not execute them.
- t Exit after reading and executing one command.
- u Treat unset variables as an error when substituting.
- v Print shell input lines as they are read.
- x Print commands and their arguments as they are executed.
- Do not change any of the flags; useful in setting `$1` to `-`.

Using `+` rather than `-` causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in `$-`. The remaining arguments are positional parameters and are assigned, in order, to `$1`, `$2`, ... If no arguments are given, the values of all names are printed.

`shift [n]`

The positional parameters from `$n+1` ... are renamed `$1` If *n* is not given, it is assumed to be 1.

`stop pid ...`

Halt execution of the process number *pid*. (see `ps(1)`).

`suspend`

Stops the execution of the current shell (but not if it is the login shell).

`test`

Evaluate conditional expressions. See `test(1)` for usage and description.

`times`

Print the accumulated user and system times for processes run from the shell.

```
trap [ argument n [ n2 . . . ] ]
```

The command *argument* is to be read and executed when the shell receives numeric or symbolic signal(s) (*n*). (Note: *argument* is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If *argument* is absent, all trap(s) *n* are reset to their original values. If *argument* is the null string, this signal is ignored by the shell and by the commands it invokes. If *n* is 0, the command *argument* is executed on exit from the shell. The `trap` command with no arguments prints a list of commands associated with each signal number.

```
type [ name . . . ]
```

For each *name*, indicate how it would be interpreted if used as a command name.

```
ulimit [ [-HS] [-a | -cdfnstv] ]
```

```
ulimit [ [-HS] [-c | -d | -f | -n | -s | -t | -v] ] limit
```

`ulimit` prints or sets hard or soft resource limits. These limits are described in `getrlimit(2)`.

If `limit` is not present, `ulimit` prints the specified limits. Any number of limits may be printed at one time. The `-a` option prints all limits.

If `limit` is present, `ulimit` sets the specified limit to `limit`. The string `unlimited` requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit. (See `su(1M)`.)

The `-H` option specifies a hard limit. The `-S` option specifies a soft limit. If neither option is specified, `ulimit` will set both limits and print the soft limit.

The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.

- `-c` maximum core file size (in 512-byte blocks)
- `-d` maximum size of data segment or heap (in kbytes)
- `-f` maximum file size (in 512-byte blocks)
- `-n` maximum file descriptor plus 1
- `-s` maximum size of stack segment (in kbytes)
- `-t` maximum CPU time (in seconds)
- `-v` maximum size of virtual memory (in kbytes)

Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` utility. See `swap(1M)`.)

sh(1)

As an example of `ulimit`, to limit the size of a core file dump to 0 Megabytes, type the following:

```
ulimit -c 0
```

```
umask [ nnn ]
```

The user file-creation mask is set to *nnn* (see `umask(1)`). If *nnn* is omitted, the current value of the mask is printed.

```
unset [ name . . . ]
```

For each *name*, remove the corresponding variable or function value. The variables `PATH`, `PS1`, `PS2`, `MAILCHECK`, and `IFS` cannot be unset.

```
wait [ n ]
```

Wait for your background process whose process id is *n* and report its termination status. If *n* is omitted, all your shell's currently active background processes are waited for and the return code will be zero.

Invocation

If the shell is invoked through `exec(2)` and the first character of argument zero is `-`, commands are initially read from `/etc/profile` and from `$HOME/.profile`, if such files exist. Thereafter, commands are read as described below, which is also the case when the shell is invoked as `/usr/bin/sh`. The flags below are interpreted by the shell on invocation only. *Note:* Unless the `-c` or `-s` flag is specified, the first argument is assumed to be the name of a file containing commands, and the remaining arguments are passed as positional parameters to that command file:

- `-c` *string* If the `-c` flag is present commands are read from *string*.
- `-i` If the `-i` flag is present or if the shell input and output are attached to a terminal, this shell is *interactive*. In this case, `TERMINATE` is ignored (so that `kill 0` does not kill an interactive shell) and `INTERRUPT` is caught and ignored (so that `wait` is interruptible). In all cases, `QUIT` is ignored by the shell.
- `-p` If the `-p` flag is present, the shell will not set the effective user and group IDs to the real user and group IDs.
- `-r` If the `-r` flag is present the shell is a restricted shell (see `rsh(1M)`).
- `-s` If the `-s` flag is present or if no arguments remain, commands are read from the standard input. Any remaining arguments specify the positional parameters. Shell output (except for `Special Commands`) is written to file descriptor 2.

The remaining flags and arguments are described under the `set` command above.

Job Control (jsh)

When the shell is invoked as `jsh`, Job Control is enabled in addition to all of the functionality described previously for `sh`. Typically, Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control.

With Job Control enabled, every command or pipeline the user enters at the terminal is called a *job*. All jobs exist in one of the following states: foreground, background, or stopped. These terms are defined as follows:

1. A job in the foreground has read and write access to the controlling terminal.
2. A job in the background is denied read access and has conditional write access to the controlling terminal (see `stty(1)`).
3. A stopped job is a job that has been placed in a suspended state, usually as a result of a `SIGTSTP` signal (see `signal(3HEAD)`).

Every job that the shell starts is assigned a positive integer, called a *job number* which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally, the shell keeps track of the *current* and *previous* jobs. The *current job* is the most recent job to be started or restarted. The *previous job* is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

`%jobid`

where *jobid* may be specified in any of the following formats:

<code>% or +</code>	For the current job.
<code>-</code>	For the previous job.
<code>?<string></code>	Specify the job for which the command line uniquely contains <i>string</i> .
<code>n</code>	For job number <i>n</i> .
<code>pref</code>	Where <i>pref</i> is a unique prefix of the command name. For example, if the command <code>ls -l name</code> were running in the background, it could be referred to as <code>%ls</code> . <i>pref</i> cannot contain blanks unless it is quoted.

When Job Control is enabled, the following commands are added to the user's environment to manipulate jobs:

`bg [%jobid . . .]`

Resumes the execution of a stopped job in the background. If *%jobid* is omitted the current job is assumed.

`fg [%jobid . . .]`

Resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If *%jobid* is omitted the current job is assumed.

`jobs [-p | -l] [%jobid . . .]`

`jobs -x command [arguments]`

Reports all jobs that are stopped or executing in the background. If *%jobid* is omitted, all jobs that are stopped or running in the background will be reported.

The following options will modify/enhance the output of `jobs`:

sh(1)

- l Report the process group ID and working directory of the jobs.
- p Report only the process group ID of the jobs.
- x Replace any *jobid* found in *command* or *arguments* with the corresponding process group ID, and then execute *command* passing it *arguments*.

kill [-signal] %jobid

Builtin version of `kill` to provide the functionality of the `kill` command for processes identified with a *jobid*.

stop %jobid . . .

Stops the execution of a background job(s).

suspend

Stops the execution of the current shell (but not if it is the login shell).

wait [%jobid . . .]

wait builtin accepts a job identifier. If %jobid is omitted wait behaves as described above under Special Commands.

Large File Behavior

See `largefile(5)` for the description of the behavior of `sh` and `jsh` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXIT STATUS

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed (see also the `exit` command above).

jsh Only

If the shell is invoked as `jsh` and an attempt is made to exit the shell while there are stopped jobs, the shell issues one warning:

There are stopped jobs.

This is the only message. If another exit attempt is made, and there are still stopped jobs they will be sent a `SIGHUP` signal from the kernel and the shell is exited.

FILES

\$HOME/.profile

/dev/null

/etc/profile

/tmp/sh*

WARNINGS The use of `setuid` shell scripts is *strongly* discouraged.

NOTES Words used for filenames in input/output redirection are not interpreted for filename generation (see File Name Generation section above). For example, `cat file1 >a*` will create a file named `a*`.

Because commands in pipelines are run as separate processes, variables set in a pipeline have no effect on the parent shell.

If you get the error message, “cannot fork, too many processes”, try using the `wait(1)` command to clean up your background processes. If this doesn’t help, the system process table is probably full or you have too many active foreground processes. There is a limit to the number of process ids associated with your login, and to the number the system can keep track of.

Only the last process in a pipeline can be waited for.

If a command is executed, and a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to exec the original command. Use the `hash` command to correct this situation.

The Bourne shell has a limitation on the effective UID for a process. If this UID is less than 100 (and not equal to the real UID of the process), then the UID is reset to the real UID of the process.

Because the shell implements both foreground and background jobs in the same process group, they all receive the same signals, which can lead to unexpected behavior. It is, therefore, recommended that other job control shells be used, especially in an interactive environment.

sh(1)

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

NAME	shell – run a command using shell				
SYNOPSIS	shell <i>command</i> [<i>command</i>] ...				
DESCRIPTION	The <code>shell</code> function concatenate its arguments, separating each by a space, and passes this string to the shell (<code>\$SHELL</code> if set, otherwise <code>/usr/bin/sh</code>).				
EXAMPLES	<p>EXAMPLE 1 A sample output of <code>shell</code> command.</p> <p>Since the Form and Menu Language does not directly support background processing, the <code>shell</code> function can be used instead.</p> <pre>`shell "build prog > /dev/null &`</pre> <p>If you want the user to continue to be able to interact with the application while the background job is running, the output of an executable run by <code>shell</code> in the background must be redirected: to a file if you want to save the output, or to <code>/dev/null</code> if you don't want to save it (or if there is no output), otherwise your application may appear to be hung until the background job finishes processing.</p> <p><code>shell</code> can also be used to execute a command that has the same name as an FMLI built-in function.</p>				
NOTES	The arguments to <code>shell</code> will be concatenate using spaces, which may or may not do what is expected. The variables set in local environments will not be expanded by the shell because "local" means "local to the current process."

shell_builtins(1)

NAME shell_builtins, case, for, foreach, function, if, repeat, select, switch, until, while – shell command interpreter built-in commands

DESCRIPTION The shell command interpreters `cs(1)`, `ks(1)`, and `sh(1)` have special built-in commands. The commands `case`, `for`, `foreach`, `function`, `if`, `repeat`, `select`, `switch`, `until`, and `while` are commands in the syntax recognized by the shells. They are described in the `Commands` section of the manual pages of the respective shells. The remaining commands listed in the table below are built into the shells for reasons such as efficiency or data sharing between command invocations. They are described on their respective manual pages.

Command	Shell
<code>alias</code>	<code>cs</code> , <code>ks</code>
<code>bg</code>	<code>cs</code> , <code>ks</code> , <code>sh</code>
<code>break</code>	<code>cs</code> , <code>ks</code> , <code>sh</code>
<code>case</code>	<code>cs</code> , <code>ks</code> , <code>sh</code>

**Bourne Shell, sh,
Special Commands**

Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional *Special Commands* are added to the shell's environment.

In addition to these built-in reserved command words, sh also uses:

- : No effect; the command does nothing. A zero exit code is returned.
- .*filename* Read and execute commands from *filename* and return. The search path specified by PATH is used to find the directory containing *filename*.

C shell, csh

Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell. In addition to these built-in reserved command words, csh also uses:

- : Null command. This command is interpreted, but performs no action.

**Korn Shell, ksh,
Special Commands**

Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is zero.

Commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

In addition to these built-in reserved command words, ksh also uses:

- * : [*arg* ...] The command only expands parameters.
- * .*file* [*arg* ...] Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by `PATH` is used to find the directory containing *file*. If any arguments *arg* are given, they become the positional parameters. Otherwise, the positional parameters are unchanged. The exit status is the exit status of the last command executed. the loop termination test.

shift(1)

NAME shift – shell built-in function to traverse either a shell’s argument list or a list of field-separated words

sh **shift** [*n*]

csh **shift** [*variable*]

ksh * **shift** [*n*]

sh The positional parameters from $\$n+1 \dots$ are renamed $\$1 \dots$. If *n* is not given, it is assumed to be 1.

csh The components of *argv*, or *variable*, if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.

ksh The positional parameters from $\$n+1 \dots$ are renamed $\$1 \dots$, default *n* is 1. The parameter *n* can be any arithmetic expression that evaluates to a non-negative number less than or equal to $\$#$.

On this man page, ksh(1) commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

NAME	shutdown – close down the system at a given time				
SYNOPSIS	<code>/usr/ucb/shutdown [-fhknr] time [warning-message...]</code>				
DESCRIPTION	<p>shutdown provides an automated procedure to notify users when the system is to be shut down. <code>time</code> specifies when shutdown will bring the system down; it may be the word <code>now</code> (indicating an immediate shutdown), or it may specify a future time in one of two formats: <code>+number</code> and <code>hour:minute</code>. The first form brings the system down in <code>number</code> minutes, and the second brings the system down at the time of day indicated in 24-hour notation.</p> <p>At intervals that get closer as the apocalypse approaches, warning messages are displayed at terminals of all logged-in users, and of users who have remote mounts on that machine.</p> <p>At shutdown time a message is written to the system log daemon, <code>syslogd(1M)</code>, containing the time of shutdown, the instigator of the shutdown, and the reason. Then a terminate signal is sent to <code>init</code>, which brings the system down to single-user mode.</p>				
OPTIONS	<p>As an alternative to the above procedure, these options can be specified:</p> <ul style="list-style-type: none"> -f Arrange, in the manner of <code>fastboot(1B)</code>, that when the system is rebooted, the file systems will not be checked. -h Execute <code>halt(1M)</code>. -k Simulate shutdown of the system. Do not actually shut down the system. -n Prevent the normal <code>sync(2)</code> before stopping. -r Execute <code>reboot(1M)</code>. 				
FILES	<code>/etc/rmtab</code> remote mounted file system table				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWscpu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWscpu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWscpu				
SEE ALSO	<code>fastboot(1B)</code> , <code>login(1)</code> , <code>halt(1M)</code> , <code>reboot(1M)</code> , <code>syslogd(1M)</code> , <code>sync(2)</code> , <code>rmtab(4)</code> , <code>attributes(5)</code>				
NOTES	Only allows you to bring the system down between <code>now</code> and <code>23:59</code> if you use the absolute time for shutdown.				

size(1)

NAME	size – print section sizes in bytes of object files
SYNOPSIS	size [-f] [-F] [-n] [-o] [-V] [-x] <i>filename...</i>
DESCRIPTION	<p>The <code>size</code> command produces segment or section size information in bytes for each loaded section in ELF object files. <code>size</code> prints out the size of the text, data, and bss (uninitialized data) segments (or sections) and their total.</p> <p><code>size</code> processes ELF object files entered on the command line. If an archive file is input to the <code>size</code> command, the information for each object file in the archive is displayed.</p> <p>When calculating segment information, the <code>size</code> command prints out the total file size of the non-writable segments, the total file size of the writable segments, and the total memory size of the writable segments minus the total file size of the writable segments.</p> <p>If it cannot calculate segment information, <code>size</code> calculates section information. When calculating section information, it prints out the total size of sections that are allocatable, non-writable, and not NOBITS, the total size of the sections that are allocatable, writable, and not NOBITS, and the total size of the writable sections of type NOBITS. NOBITS sections do not actually take up space in the <i>filename</i>.</p> <p>If <code>size</code> cannot calculate either segment or section information, it prints an error message and stops processing the file.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-f Prints out the size of each allocatable section, the name of the section, and the total of the section sizes. If there is no section data, <code>size</code> prints out an error message and stops processing the file.-F Prints out the size of each loadable segment, the permission flags of the segment, then the total of the loadable segment sizes. If there is no segment data, <code>size</code> prints an error message and stops processing the file.-n Prints out non-loadable segment or non-allocatable section sizes. If segment data exists, <code>size</code> prints out the memory size of each loadable segment or file size of each non-loadable segment, the permission flags, and the total size of the segments. If there is no segment data, <code>size</code> prints out, for each allocatable and non-allocatable section, the memory size, the section name, and the total size of the sections. If there is no segment or section data, <code>size</code> prints an error message and stops processing.-o Prints numbers in octal, not decimal.-V Prints the version information for the <code>size</code> command on the standard error output.-x Prints numbers in hexadecimal, not decimal.
EXAMPLES	The examples below are typical <code>size</code> output.

EXAMPLE 1

```
example% size filename
2724 + 88 + 0 = 2812
```

EXAMPLE 2

```
example% size -f filename
26(.text) + 5(.init) + 5(.fini) = 36
```

EXAMPLE 3

```
example% size -F filename
2724(r-x) + 88(rwx) + 0(rwx) = 2812 ... (If statically linked)
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

SEE ALSO `as(1)`, `cc(1B)`, `ld(1)`, `ar(3HEAD)`, `a.out(4)`, `attributes(5)`

NOTES Since the size of bss sections is not known until link-edit time, the `size` command will not give the true total size of pre-linked objects.

sleep(1)

NAME	sleep – suspend execution for an interval						
SYNOPSIS	sleep <i>time</i>						
DESCRIPTION	The <code>sleep</code> utility will suspend execution for at least the integral number of seconds specified by the <i>time</i> operand.						
OPERANDS	The following operands are supported: <i>time</i> A non-negative decimal integer specifying the number of seconds for which to suspend execution.						
EXAMPLES	EXAMPLE 1 Suspending command execution for a time To execute a command after a certain amount of time: example% (sleep 105; <i>command</i>) & EXAMPLE 2 Executing a command every so often example% while true do <i>command</i> sleep 37 done						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>sleep</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS	The following exit values are returned: 0 The execution was successfully suspended for at least <i>time</i> seconds, or a <code>SIGALRM</code> signal was received (see NOTES). >0 An error has occurred.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr><tr><td>Interface Stability</td><td>Standard</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	Interface Stability	Standard
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWcsu						
Interface Stability	Standard						
SEE ALSO	<code>wait(1)</code> , <code>alarm(2)</code> , <code>sleep(3C)</code> , <code>wait(3UCB)</code> , <code>attributes(5)</code> , <code>environ(5)</code> , <code>standards(5)</code>						
NOTES	If the <code>sleep</code> utility receives a <code>SIGALRM</code> signal, one of the following actions will be taken: <ul style="list-style-type: none">■ Terminate normally with a zero exit status.						

sleep(1)

- Effectively ignore the signal.

The `sleep` utility will take the standard action for all other signals.

smart2cfg(1)

NAME	smart2cfg – Compaq Smart-2 EISA/PCI and Smart-2SL PCI Array Controller ioctl utility
SYNOPSIS	<pre>smart2cfg -c [controller_num] smart2cfg -d [controller_num] smart2cfg -h smart2cfg -l logical_drive_num [controller_num] smart2cfg -p physical_drive_num bus_num [controller_num]</pre>
DESCRIPTION	<p>The <code>smart2cfg</code> utility issues controller-specific ioctls to the Compaq Smart-2 EISA/PCI and Smart-2SL PCI array controller using the <code>smartii(7D)</code> driver.</p> <p><code>smart2cfg</code> provides information about the Smart-2 and Smart-2SL controllers installed on the system, the Logical and Physical drives as well as the details of the ReadWrite cache present on each controller. The utility is text based and is driven by command line arguments. <code>smart2cfg</code> and the <code>smartii(7D)</code> driver communicate using ioctls. <code>smart2cfg</code> also supports multiple commands.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-c <i>controller_num</i> Prints cache details of the cache on controller <i>controller_num</i>.-d <i>controller_num</i> Prints details of all the physical disks, all the logical drives, and the cache on controller <i>controller_num</i>.-h Provides on-line help for the <code>smart2cfg</code> utility.-l <i>logical_drive_num controller_num</i> Prints logical drive details of the drive <i>logical_drive_num</i> on controller <i>controller_num</i>.-p <i>physical_drive_num bus_num controller_num</i> Prints physical drive details of the disk <i>physical_drive_num</i> on bus <i>bus_num</i> on controller <i>controller_num</i>.
EXAMPLES	<p>EXAMPLE 1 Providing details of the physical disk</p> <p>To provide details of the physical disk with SCSI ID 0, on Bus 0, on controller 0:</p> <pre>example% smart2cfg -p -0 0 0</pre> <p>EXAMPLE 2 Providing logical drive details</p> <p>To provide logical drive details of logical drive 0 on controller 0:</p> <pre>example% smart2cfg -l 0 0</pre>

EXAMPLE 3 Providing cache details

To provide cache details of controller 0:

```
example% smart2cfg -c 0
```

EXAMPLE 4 Providing information of all physical disks, logical drives, and cache on a controller

To provide information on all physical disks, logical drives, and cache on controller 0:

```
smart2cfg -d
```

EXAMPLE 5 Providing details of the disk

To provide details of the disk with SCSI ID 0, on Bus 0, on controller 0, and logical drive details of logical drive 0 on controller 1:

```
example% smart2cfg -p 0 0 0 -1 0 1
```

FILES /devices/eisa/smartii@<instance>, <ioaddr>:ioctlnode
 /devices/pci@0, <bus_num>/pci1014,22@<device_num>/pcie11,4030@0:ioctlnode
 /devices/pci@0, <bus_num>/pci1014,22@<device_num>/pcie11,4031@0:ioctlnode

NOTES If the controller is not specified, the first controller is taken as default.

soelim(1)

NAME | soelim – resolve and eliminate .so requests from nroff or troff input

SYNOPSIS | **soelim** [*filename...*]

DESCRIPTION | soelim reads the specified files or the standard input and performs the textual inclusion implied by the nroff(1) directives of the form

.so somefile

when they appear at the beginning of input lines. This is useful since programs such as tbl(1) do not normally do this; it allows the placement of individual tables in separate files to be run as a part of a large document.

An argument consisting of '-' is taken to be a file name corresponding to the standard input.

Note: Inclusion can be suppressed by using ' ' instead of ' . ', that is,

' so /usr/share/lib/tmac/tmac.s

EXAMPLES | **EXAMPLE 1** A sample of the soelim command.

A sample usage of soelim would be

example% soelim exum?.n | tbl | nroff -ms | col | lpr

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

SEE ALSO | more(1), nroff(1), tbl(1), attributes(5)

NAME	solregis – Solaris user registration																																						
SYNOPSIS	<code>/usr/dt/bin/solregis [-dc]</code>																																						
DESCRIPTION	The <code>solregis</code> command initiates the Solaris user registration procedure. This allows users to register with Sun Microsystems and receive information about Solaris. Normally, <code>solregis</code> is executed in conditional mode as a part of desktop login so that users are prompted at desktop start up time to register, unless they have already done so.																																						
OPTIONS	The following options are supported:																																						
	<code>-d</code>	Delay display of the initial screen until a window manager has asserted control of the X display.																																					
	<code>-c</code>	Conditional mode. If specified, <code>solregis</code> will exit without any dialog displayed if: (1) <code>\$HOME/.solregis/disable</code> exists, (2) <code>DISABLE=1</code> is specified in <code>/etc/default/solregis</code> , or (3) the user has already registered.																																					
USAGE	The following resources can control the behavior and appearance of <code>solregis</code> :																																						
	<table border="1"> <thead> <tr> <th>Name</th> <th>Class</th> <th>Value Type</th> <th>Default</th> </tr> </thead> <tbody> <tr> <td><code>disable</code></td> <td>Disable</td> <td>Boolean</td> <td>False</td> </tr> <tr> <td><code>localeChoices</code></td> <td>LocaleChoices</td> <td>Int</td> <td>1</td> </tr> <tr> <td><code>action0</code></td> <td>Action</td> <td>String</td> <td><code>/usr/dt/bin/hotjava</code></td> </tr> <tr> <td><code>initialURL0</code></td> <td>URL</td> <td>String</td> <td><code>file:///usr/dt/app-config \</code> <code>/solregis/EReg.html</code></td> </tr> <tr> <td><code>localeChoicen</code></td> <td>LocaleChoice</td> <td>String</td> <td>null</td> </tr> <tr> <td><code>actionn</code></td> <td>Action</td> <td>String</td> <td>null for $n>0$</td> </tr> <tr> <td><code>initialURLn</code></td> <td>URL</td> <td>String</td> <td>null for $n>0$</td> </tr> <tr> <td><code>printContext</code></td> <td>PrintContext</td> <td>String</td> <td><code>thisorgunit</code></td> </tr> </tbody> </table>			Name	Class	Value Type	Default	<code>disable</code>	Disable	Boolean	False	<code>localeChoices</code>	LocaleChoices	Int	1	<code>action0</code>	Action	String	<code>/usr/dt/bin/hotjava</code>	<code>initialURL0</code>	URL	String	<code>file:///usr/dt/app-config \</code> <code>/solregis/EReg.html</code>	<code>localeChoicen</code>	LocaleChoice	String	null	<code>actionn</code>	Action	String	null for $n>0$	<code>initialURLn</code>	URL	String	null for $n>0$	<code>printContext</code>	PrintContext	String	<code>thisorgunit</code>
Name	Class	Value Type	Default																																				
<code>disable</code>	Disable	Boolean	False																																				
<code>localeChoices</code>	LocaleChoices	Int	1																																				
<code>action0</code>	Action	String	<code>/usr/dt/bin/hotjava</code>																																				
<code>initialURL0</code>	URL	String	<code>file:///usr/dt/app-config \</code> <code>/solregis/EReg.html</code>																																				
<code>localeChoicen</code>	LocaleChoice	String	null																																				
<code>actionn</code>	Action	String	null for $n>0$																																				
<code>initialURLn</code>	URL	String	null for $n>0$																																				
<code>printContext</code>	PrintContext	String	<code>thisorgunit</code>																																				
	<code>disable</code>	If <code>TRUE</code> , when executed in conditional mode <code>solregis</code> simply exits without displaying anything.																																					
	<code>localeChoices</code>	Specifies the number of <code>localeChoicen</code> , <code>actionn</code> and <code>initialURLn</code> sets. The first set is 0, so if <code>localeChoices</code> is 1, <code>localeChoice0</code> , <code>action0</code> , and <code>initialURL0</code> are the only active resources. If <code>localeChoices</code> is 1, none of the <code>localeChoicen</code> strings are displayed, and <code>action0</code> , and so forth. are																																					

solregis(1)

	used. If <code>localeChoices</code> is greater than 1, each <code>localeChoice<i>n</i></code> string is made an element in an exclusive choice list and the index of the selected item controls which <code>action<i>n</i></code> and <code>initialURL<i>n</i></code> resources are applied.
	<code>localeChoice<i>n</i></code> Specifies the string presented to the user for this choice.
	<code>action<i>n</i></code> Specifies the file name of the command to be executed (normally expected to be a World Wide Web browser) when the user selects "Register Now", or the special string "print". If "print" is specified, the <code>initialURL<i>n</i></code> string must be a file name on the local system, naming a file which is to be printed after prompting the user for a print destination.
	<code>initialURL<i>n</i></code> Specifies the argument to be passed to <code>action<i>n</i></code> for initial registration. This will normally be the Universal Resource Locator for the initial page to be displayed by the World Wide Web browser.
	<code>printContext</code> XFN naming context under which the printers to display to the user if the special "print" action are named, in the service/printer context. For example, if the default <code>printContext</code> "thisorgunit" is used, the printers in <code>thisorgunit/service/printer</code> are displayed.
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>solregis</code> : <code>HOME</code> , <code>LANG</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.
FILES	<code>/etc/default/solregis</code> Default values. <code>/\$HOME/.solregis/uprops</code> User registration information. <code>/\$HOME/.solregis/disable</code> Users disabled from registration. <code>/usr/dt/app-defaults/C/Solregis</code> Default locale resources. <code>/usr/dt/app-defaults/\$LANG/Solregis</code> Default localized resources.

solregis(1)

/etc/dt/app-defaults/C/Solregis
Default installation resources.

/usr/dt/app-defaults/\$LANG/Solregis
Localized installation resources.

sort(1)

NAME	sort – sort, merge, or sequence check text files
SYNOPSIS	<pre> /usr/bin/sort [-bcdfimMnru] [-k <i>keydef</i>] [-o <i>output</i>] [-S <i>kmem</i>] [-t <i>char</i>] [-T <i>directory</i>] [-y [<i>kmem</i>]] [-z <i>recsz</i>] [+pos1 [-pos2]] [<i>file...</i>] /usr/xpg4/bin/sort [-bcdfimMnru] [-k <i>keydef</i>] [-o <i>output</i>] [-S <i>kmem</i>] [-t <i>char</i>] [-T <i>directory</i>] [-y [<i>kmem</i>]] [-z <i>recsz</i>] [+pos1 [-pos2]] [<i>file...</i>] </pre>
DESCRIPTION	<p>The <code>sort</code> command sorts lines of all the named files together and writes the result on the standard output.</p> <p>Comparisons are based on one or more sort keys extracted from each line of input. By default, there is one sort key, the entire input line. Lines are ordered according to the collating sequence of the current locale.</p>
OPTIONS	The following options alter the default behavior:
/usr/bin/sort	<p>-c Checks that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. The exit code is set and no output is produced unless the file is out of sort.</p>
/usr/xpg4/bin/sort	<p>-c Same as <code>/usr/bin/sort</code> except no output is produced under any circumstances.</p> <p>-m Merges only. The input files are assumed to be already sorted.</p> <p>-o <i>output</i> Specifies the name of an output file to be used instead of the standard output. This file can be the same as one of the input files.</p> <p>-S <i>kmem</i> Specifies the maximum amount of swap-based memory used for sorting, in kilobytes (the default unit). <i>kmem</i> can also be specified directly as a number of bytes (b), kilobytes (k), megabytes (m), gigabytes (g), or terabytes (t); or as a percentage (%) of the installed physical memory.</p> <p>-T <i>directory</i> Specifies the <i>directory</i> in which to place temporary files.</p> <p>-u Unique: suppresses all but one in each set of lines having equal keys. If used with the <code>-c</code> option, checks that there are no lines with duplicate keys in addition to checking that the input file is sorted.</p> <p>-y <i>kmem</i> (obsolete). This option was used to specify the amount of main memory initially used by <code>sort</code>. Its functionality is not appropriate for a virtual memory system; memory usage for <code>sort</code> is now specified using the <code>-S</code> option.</p> <p>-z <i>recsz</i> (obsolete). This option was used to prevent abnormal termination when lines longer than the system-dependent default buffer size are encountered. Because <code>sort</code> automatically allocates buffers large enough to hold the longest line, this option has no effect.</p>

Ordering Options

The default sort order depends on the value of `LC_COLLATE`. If `LC_COLLATE` is set to `C`, sorting will be in ASCII order. If `LC_COLLATE` is set to `en_US`, sorting is case insensitive except when the two strings are otherwise equal and one has an uppercase letter earlier than the other. Other locales will have other sort orders.

The following options override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules are applied globally to all sort keys. When attached to a specific key (see *Sort Key Options*), the specified ordering options override all global ordering options for that key. In the obsolescent forms, if one or more of these options follows a *+pos1* option, it will affect only the key field specified by that preceding option.

- d “Dictionary” order: only letters, digits, and blanks (spaces and tabs) are significant in comparisons.
- f Folds lower-case letters into upper case.
- i Ignores non-printable characters.
- M Compares as months. The first three non-blank characters of the field are folded to upper case and compared. For example, in English the sorting order is "JAN" < "FEB" < . . . < "DEC". Invalid fields compare low to "JAN". The `-M` option implies the `-b` option (see below).
- n Restricts the sort key to an initial numeric string, consisting of optional blank characters, optional minus sign, and zero or more digits with an optional radix character and thousands separators (as defined in the current locale), which will be sorted by arithmetic value. An empty digit string is treated as zero. Leading zeros and signs on zeros do not affect ordering.
- r Reverses the sense of comparisons.

Field Separator Options

The treatment of field separators can be altered using the following options:

- b Ignores leading blank characters when determining the starting and ending positions of a restricted sort key. If the `-b` option is specified before the first sort key option, it is applied to all sort key options. Otherwise, the `-b` option can be attached independently to each `-k field_start, field_end`, or *+pos1* or *-pos2* option-argument (see below).
- t *char* Use *char* as the field separator character. *char* is not considered to be part of a field (although it can be included in a sort key). Each occurrence of *char* is significant (for example, `<char><char>` delimits an empty field). If `-t` is not specified, blank characters are used as default field separators; each maximal non-empty sequence of blank characters that follows a non-blank character is a field separator.

sort(1)

Sort Key Options

Sort keys can be specified using the options:

-k keydef The *keydef* argument is a restricted sort key field definition. The format of this definition is:

```
-k field_start [type] [ ,field_end [type] ]
```

where:

field_start and *field_end*

define a key field restricted to a portion of the line.

type

is a modifier from the list of characters `bdfiMnr`. The `b` modifier behaves like the `-b` option, but applies only to the *field_start* or *field_end* to which it is attached and characters within a field are counted from the first non-blank character in the field. (This applies separately to *first_character* and *last_character*.) The other modifiers behave like the corresponding options, but apply only to the key field to which they are attached. They have this effect if specified with *field_start*, *field_end* or both. If any modifier is attached to a *field_start* or to a *field_end*, no option applies to either.

When there are multiple key fields, later keys are compared only after all earlier keys compare equal. Except when the `-u` option is specified, lines that otherwise compare equal are ordered as if none of the options `-d`, `-f`, `-i`, `-n` or `-k` were present (but with `-r` still in effect, if it was specified) and with all bytes in the lines significant to the comparison.

The notation:

```
-k field_start [type] [ ,field_end [type] ]
```

defines a key field that begins at *field_start* and ends at *field_end* inclusive, unless *field_start* falls beyond the end of the line or after *field_end*, in which case the key field is empty. A missing *field_end* means the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option `-t`, any preceding field separator.

The *field_start* portion of the *keydef* option-argument has the form:

```
field_number [ .first_character ]
```

Fields and characters within fields are numbered starting with 1. *field_number* and *first_character*, interpreted as positive decimal integers, specify the first character to be used as part of a sort key. If *first_character* is omitted, it refers to the first character of the field.

sort(1)

The *field_end* portion of the *keydef* option-argument has the form:

field_number [. *last_character*]

The *field_number* is as described above for *field_start*. *last_character*, interpreted as a non-negative decimal integer, specifies the last character to be used as part of the sort key. If *last_character* evaluates to zero or *last_character* is omitted, it refers to the last character of the field specified by *field_number*.

If the *-b* option or *b* type modifier is in effect, characters within a field are counted from the first non-blank character in the field. (This applies separately to *first_character* and *last_character*.)

[*+pos1* [*-pos2*]] (obsolete). Provide functionality equivalent to the *-kkeydef* option.

pos1 and *pos2* each have the form *m.n* optionally followed by one or more of the flags *bdfiMnr*. A starting position specified by *+m.n* is interpreted to mean the *n*+1st character in the *m*+1st field. A missing *.n* means *.0*, indicating the first character of the *m*+1st field. If the *b* flag is in effect *n* is counted from the first non-blank in the *m*+1st field; *+m.0b* refers to the first non-blank character in the *m*+1st field.

A last position specified by *-m.n* is interpreted to mean the *n*th character (including separators) after the last character of the *m*th field. A missing *.n* means *.0*, indicating the last character of the *m*th field. If the *b* flag is in effect *n* is counted from the last leading blank in the *m*+1st field; *-m.1b* refers to the first non-blank in the *m*+1st field.

The fully specified *+pos1 -pos2* form with type modifiers *T* and *U*:

+w.xT -y.zU

is equivalent to:

```
undefined          (z==0 & U contains b & -t is present)
-k w+1.x+1T,y.0U   (z==0 otherwise)
-k w+1.x+1T,y+1.zU (z > 0)
```

Implementations support at least nine occurrences of the sort keys (the *-k* option and obsolescent *+pos1* and *-pos2*) which are significant in command line order. If no sort key is specified, a default sort key of the entire line is used.

OPERANDS The following operand is supported:

file A path name of a file to be sorted, merged or checked. If no *file* operands are specified, or if a *file* operand is *-*, the standard input will be used.

sort(1)

USAGE See `largefile(5)` for the description of the behavior of `sort` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES In the following examples, first the preferred and then the obsolete way of specifying `sort` keys are given as an aid to understanding the relationship between the two forms.

EXAMPLE 1 Sorting with the second field as a sort key

Either of the following commands sorts the contents of `infile` with the second field as the sort key:

```
example% sort -k 2,2 infile
example% sort +1 -2 infile
```

EXAMPLE 2 Sorting in reverse order

Either of the following commands sorts, in reverse order, the contents of `infile1` and `infile2`, placing the output in `outfile` and using the second character of the second field as the sort key (assuming that the first character of the second field is the field separator):

```
example% sort -r -o outfile -k 2.2,2.2 infile1 infile2
example% sort -r -o outfile +1.1 -1.2 infile1 infile2
```

EXAMPLE 3 Sorting using a specified character in one of the files

Either of the following commands sorts the contents of `infile1` and `infile2` using the second non-blank character of the second field as the sort key:

```
example% sort -k 2.2b,2.2b infile1 infile2
example% sort +1.1b -1.2b infile1 infile2
```

EXAMPLE 4 Sorting by numeric user ID

Either of the following commands prints the `passwd(4)` file (user database) sorted by the numeric user ID (the third colon-separated field):

```
example% sort -t : -k 3,3n /etc/passwd
example% sort -t : +2 -3n /etc/passwd
```

EXAMPLE 5 Printing sorted lines excluding lines that duplicate a field

Either of the following commands prints the lines of the already sorted file `infile`, suppressing all but one occurrence of lines having the same third field:

```
example% sort -um -k 3.1,3.0 infile
example% sort -um +2.0 -3.0 infile
```

EXAMPLE 6 Sorting by host IP address

Either of the following commands prints the `hosts(4)` file (IPv4 hosts database), sorted by the numeric IP address (the first four numeric fields):

```
example$ sort -t . -k 1,1n -k 2,2n -k 3,3n -k 4,4n /etc/hosts
example$ sort -t . +0 -1n +1 -2n +2 -3n +3 -4n /etc/hosts
```

Since `'.'` is both the field delimiter and, in many locales, the decimal separator, failure to specify both ends of the field will lead to results where the second field is interpreted as a fractional portion of the first, and so forth.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sort`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_MESSAGES`, and `NLSPATH`.

`LC_CTYPE` Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single- versus multi-byte characters in arguments and input files) and the behavior of character classification for the `-b`, `-d`, `-f`, `-i` and `-n` options.

`LC_NUMERIC` Determine the locale for the definition of the radix character and thousands separator for the `-n` option.

EXIT STATUS

The following exit values are returned:

- 0 All input files were output successfully, or `-c` was specified and the input file was correctly sorted.
- 1 Under the `-c` option, the file was not ordered as specified, or if the `-c` and `-u` options were both specified, two input lines were found with equal keys.
- >1 An error occurred.

FILES

`/var/tmp/stm???` temporary files

sort(1)

SEE ALSO | comm(1), join(1), uniq(1), nl_langinfo(3C), strftime(3C), hosts(4), passwd(4), attributes(5), environ(5), largefile(5), standards(5)

DIAGNOSTICS | Comments and exits with non-zero status for various trouble conditions (for example, when input lines are too long), and for disorders discovered under the `-c` option.

NOTES | When the last line of an input file is missing a new-line character, `sort` appends one, prints a warning message, and continues.

`sort` does not guarantee preservation of relative line ordering on equal keys.

One can tune `sort` performance for a specific scenario using the `-S` option. However, one should note in particular that `sort` has greater knowledge of how to use a finite amount of memory for sorting than the virtual memory system. Thus, a `sort` invoked to request an extremely large amount of memory via the `-S` option could perform extremely poorly.

As noted, certain of the field modifiers (such as `-M` and `-d`) cause the interpretation of input data to be done with reference to locale-specific settings. The results of this interpretation can be unexpected if one's expectations are not aligned with the conventions established by the locale. In the case of the month keys, `sort` does not attempt to compensate for "approximate" month abbreviations. The precise month abbreviations from `nl_langinfo(3C)` or `strftime(3C)` are the only ones recognized. For printable or dictionary order, if these concepts are not well-defined by the locale, an empty sort key may be the result, leading to the next key being the significant one for determining the appropriate ordering.

NAME	sortbib – sort a bibliographic database																																														
SYNOPSIS	sortbib [-s <i>KEYS</i>] <i>database</i> ...																																														
DESCRIPTION	<p>sortbib sorts files of records containing <i>refer</i> key-letters by user-specified keys. Records may be separated by blank lines, or by ‘. [‘ and ‘.]’ delimiters, but the two styles may not be mixed together. This program reads through each <i>database</i> and pulls out key fields, which are sorted separately. The sorted key fields contain the file pointer, byte offset, and length of corresponding records. These records are delivered using disk seeks and reads, so <i>sortbib</i> may not be used in a pipeline to read standard input.</p> <p>The most common key-letters and their meanings are given below.</p> <table border="0"> <tr><td>%A</td><td>Author’s name</td></tr> <tr><td>%B</td><td>Book containing article referenced</td></tr> <tr><td>%C</td><td>City (place of publication)</td></tr> <tr><td>%D</td><td>Date of publication</td></tr> <tr><td>%E</td><td>Editor of book containing article referenced</td></tr> <tr><td>%F</td><td>Footnote number or label (supplied by <i>refer</i>)</td></tr> <tr><td>%G</td><td>Government order number</td></tr> <tr><td>%H</td><td>Header commentary, printed before reference</td></tr> <tr><td>%I</td><td>Issuer (publisher)</td></tr> <tr><td>%J</td><td>Journal containing article</td></tr> <tr><td>%K</td><td>Keywords to use in locating reference</td></tr> <tr><td>%L</td><td>Label field used by -k option of <i>refer</i></td></tr> <tr><td>%M</td><td>Bell Labs Memorandum (undefined)</td></tr> <tr><td>%N</td><td>Number within volume</td></tr> <tr><td>%O</td><td>Other commentary, printed at end of reference</td></tr> <tr><td>%P</td><td>Page number(s)</td></tr> <tr><td>%Q</td><td>Corporate or Foreign Author (unreversed)</td></tr> <tr><td>%R</td><td>Report, paper, or thesis (unpublished)</td></tr> <tr><td>%S</td><td>Series title</td></tr> <tr><td>%T</td><td>Title of article or book</td></tr> <tr><td>%V</td><td>Volume number</td></tr> <tr><td>%X</td><td>Abstract — used by <i>roffbib</i>, not by <i>refer</i></td></tr> <tr><td>%Y, Z</td><td>Ignored by <i>refer</i></td></tr> </table>	%A	Author’s name	%B	Book containing article referenced	%C	City (place of publication)	%D	Date of publication	%E	Editor of book containing article referenced	%F	Footnote number or label (supplied by <i>refer</i>)	%G	Government order number	%H	Header commentary, printed before reference	%I	Issuer (publisher)	%J	Journal containing article	%K	Keywords to use in locating reference	%L	Label field used by -k option of <i>refer</i>	%M	Bell Labs Memorandum (undefined)	%N	Number within volume	%O	Other commentary, printed at end of reference	%P	Page number(s)	%Q	Corporate or Foreign Author (unreversed)	%R	Report, paper, or thesis (unpublished)	%S	Series title	%T	Title of article or book	%V	Volume number	%X	Abstract — used by <i>roffbib</i> , not by <i>refer</i>	%Y, Z	Ignored by <i>refer</i>
%A	Author’s name																																														
%B	Book containing article referenced																																														
%C	City (place of publication)																																														
%D	Date of publication																																														
%E	Editor of book containing article referenced																																														
%F	Footnote number or label (supplied by <i>refer</i>)																																														
%G	Government order number																																														
%H	Header commentary, printed before reference																																														
%I	Issuer (publisher)																																														
%J	Journal containing article																																														
%K	Keywords to use in locating reference																																														
%L	Label field used by -k option of <i>refer</i>																																														
%M	Bell Labs Memorandum (undefined)																																														
%N	Number within volume																																														
%O	Other commentary, printed at end of reference

%V	Volume number																																														
%X	Abstract — used by <i>roffbib</i> , not by <i>refer</i>																																														
%Y, Z	Ignored by <i>refer</i>																																														

sortbib(1)

By default, `sortbib` alphabetizes by the first `%A` and the `%D` fields, which contain the senior author and date.

`sortbib` sorts on the last word on the `%A` line, which is assumed to be the author's last name. A word in the final position, such as 'jr.' or 'ed.', will be ignored if the name beforehand ends with a comma. Authors with two-word last names or unusual constructions can be sorted correctly by using the `nroff` convention '\0' in place of a blank. A `%Q` field is considered to be the same as `%A`, except sorting begins with the first, not the last, word. `sortbib` sorts on the last word of the `%D` line, usually the year. It also ignores leading articles (like 'A' or 'The') when sorting by titles in the `%T` or `%J` fields; it will ignore articles of any modern European language. If a sort-significant field is absent from a record, `sortbib` places that record before other records containing that field.

No more than 16 databases may be sorted together at one time. Records longer than 4096 characters will be truncated.

OPTIONS `-sKEYS` Specify new *KEYS*. For instance, `-sATD` will sort by author, title, and date, while `-sA+D` will sort by all authors, and date. Sort keys past the fourth are not meaningful.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

SEE ALSO `addbib(1)`, `indxbib(1)`, `lookbib(1)`, `refer(1)`, `roffbib(1)`, `attributes(5)`

BUGS Records with missing author fields should probably be sorted by title.

NAME	sotruss – trace shared library procedure calls
SYNOPSIS	<code>/usr/bin/sotruss [-f] [-F <i>bindfromlist</i>] [-T <i>bindtolist</i>] [-o <i>outputfile</i>] executable [<i>executable arguments...</i>]</code>
DESCRIPTION	sotruss executes the specified command and produces a trace of the library calls that it performs. Each line of the trace output reports what bindings are occurring between dynamic objects as each procedure call is executed. sotruss traces all of the procedure calls that occur between dynamic objects via the <i>Procedure Linkage Table</i> , so only those procedure calls which are bound via the <i>Procedure Linkage Table</i> will be traced. See <i>Linker and Libraries Guide</i>
OPTIONS	<p><code>-F <i>bindfromlist</i></code> A colon-separated list of libraries that are to be traced. Only calls from these libraries will be traced. The default is to trace calls from the main executable only.</p> <p><code>-T <i>bindtolist</i></code> A colon-separated list of libraries that are to be traced. Only calls to these libraries will be traced. The default is to trace all calls.</p> <p><code>-o <i>outputfile</i></code> sotruss output will be directed to the <i>outputfile</i>. If this option is combined with the <code>-f</code> option then the <i>pid</i> of the executing program will be placed at the end of the filename. By default sotruss output is placed on <code>stderr</code>.</p> <p><code>-f</code> Follow all children created by <code>fork()</code> and print <code>truss</code> output on each child process. This option will also cause a <i>pid</i> to be output on each <code>truss</code> output line.</p>
EXAMPLES	<p>EXAMPLE 1 An example of sotruss.</p> <p>A simple example shows the tracing of a simple <code>ls</code> command:</p> <pre>% sotruss ls more ls -> libc.so.1:*atexit(0xef7d7d1c, 0x23c00, 0x0) ls -> libc.so.1:*atexit(0x1392c, 0xef7d7d1c, 0xef621bb0) ls -> libc.so.1:*setlocale(0x6, 0x1396c, 0xef621ba8) ls -> libc.so.1:*textdomain(0x13970, 0x1396c, 0xef621ba8) ls -> libc.so.1:*time(0x0, 0xef61f6fc, 0xef621ba8) ls -> libc.so.1:*isatty(0x1, 0xef61f6fc, 0x0) ls -> libc.so.1:*getopt(0x1, 0xfffff8fc, 0x13980) ls -> libc.so.1:*malloc(0x100, 0x0, 0x0) ls -> libc.so.1:*malloc(0x9000, 0x0, 0x0) ls -> libc.so.1:*lstat64(0x23ee8, 0xfffff7a0, 0x0) . . . ls -> libc.so.1:*printf(0x13a64, 0x26208, 0x23ef0) ls -> libc.so.1:*printf(0x13a64, 0x26448, 0x23ef0) ls -> libc.so.1:*exit(0x0, 0x24220, 0x2421c)</pre>

Linker and Libraries Guide

NAME	spell, hashmake, spellin, hashcheck – report spelling errors								
SYNOPSIS	<pre>spell [-bilvx] [+ local_file] [file] ... /usr/lib/spell/hashmake /usr/lib/spell/spellin n /usr/lib/spell/hashcheck spelling_list</pre>								
DESCRIPTION	<p>The <code>spell</code> command collects words from the named <code>files</code> and looks them up in a spelling list. Words that neither occur among nor are derivable (by applying certain inflections, prefixes, or suffixes) from words in the spelling list are written to the standard output.</p> <p>If there are no <code>file</code> arguments, words to check are collected from the standard input. <code>spell</code> ignores most <code>troff(1)</code>, <code>tbl(1)</code>, and <code>eqr(1)</code> constructs. Copies of all output words are accumulated in the history file (<code>spellhist</code>), and a <code>stop</code> list filters out misspellings (for example, <code>their=thy-y+ier</code>) that would otherwise pass.</p> <p>By default, <code>spell</code> (like <code>deroff(1)</code>) follows chains of included files (<code>.so</code> and <code>.nx</code> <code>troff(1)</code> requests), unless the names of such included files begin with <code>/usr/lib</code>.</p> <p>The standard spelling list is based on many sources, and while more haphazard than an ordinary dictionary, is also more effective in respect to proper names and popular technical words. Coverage of the specialized vocabularies of biology, medicine and chemistry is light.</p> <p>Three programs help maintain and check the hash lists used by <code>spell</code>:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>hashmake</code></td> <td>Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.</td> </tr> <tr> <td><code>spellin</code></td> <td>Reads <code>n</code> hash codes from the standard input and writes a compressed spelling list on the standard output.</td> </tr> <tr> <td><code>hashcheck</code></td> <td>Reads a compressed <code>spelling_list</code> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.</td> </tr> </table>	<code>hashmake</code>	Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.	<code>spellin</code>	Reads <code>n</code> hash codes from the standard input and writes a compressed spelling list on the standard output.	<code>hashcheck</code>	Reads a compressed <code>spelling_list</code> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.		
<code>hashmake</code>	Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.								
<code>spellin</code>	Reads <code>n</code> hash codes from the standard input and writes a compressed spelling list on the standard output.								
<code>hashcheck</code>	Reads a compressed <code>spelling_list</code> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.								
OPTIONS	<p>The following options are supported:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>-b</code></td> <td>Check British spelling. Besides preferring "centre," "colour," "programme," "speciality," "travelled," and so forth, this option insists upon <code>-ise</code> in words like "standardise."</td> </tr> <tr> <td><code>-i</code></td> <td>Cause <code>deroff(1)</code> to ignore <code>.so</code> and <code>.nx</code> commands. If <code>deroff(1)</code> is not present on the system, then this option is ignored.</td> </tr> <tr> <td><code>-l</code></td> <td>Follow the chains of <i>all</i> included files.</td> </tr> <tr> <td><code>-v</code></td> <td>Print all words not literally in the spelling list, as well as plausible derivations from the words in the spelling list.</td> </tr> </table>	<code>-b</code>	Check British spelling. Besides preferring "centre," "colour," "programme," "speciality," "travelled," and so forth, this option insists upon <code>-ise</code> in words like "standardise."	<code>-i</code>	Cause <code>deroff(1)</code> to ignore <code>.so</code> and <code>.nx</code> commands. If <code>deroff(1)</code> is not present on the system, then this option is ignored.	<code>-l</code>	Follow the chains of <i>all</i> included files.	<code>-v</code>	Print all words not literally in the spelling list, as well as plausible derivations from the words in the spelling list.
<code>-b</code>	Check British spelling. Besides preferring "centre," "colour," "programme," "speciality," "travelled," and so forth, this option insists upon <code>-ise</code> in words like "standardise."								
<code>-i</code>	Cause <code>deroff(1)</code> to ignore <code>.so</code> and <code>.nx</code> commands. If <code>deroff(1)</code> is not present on the system, then this option is ignored.								
<code>-l</code>	Follow the chains of <i>all</i> included files.								
<code>-v</code>	Print all words not literally in the spelling list, as well as plausible derivations from the words in the spelling list.								

spell(1)

-x Print every plausible stem, one per line, with = preceding each word.

+local_file Specify a set of words that are correct spellings (in addition to spell's own spelling list) for each job. *local_file* is the name of a user-provided file that contains a sorted list of words, one per line. Words found in *local_file* are removed from spell's output. Use `sort(1)` to order *local_file* in ASCII collating sequence. If this ordering is not followed, some entries in *local_file* may be ignored.

OPERANDS The following operands are supported:

file A path name of a text file to check for spelling errors. If no files are named, words are collected from the standard input.

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `spell`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES `D_SPELL=/usr/lib/spell/hlist [ab]`
hashed spelling lists, American & British

`S_SPELL=/usr/lib/spell/hstop`
hashed stop list

`H_SPELL=/var/adm/spellhist`
history file

`/usr/share/lib/dict/words`
master dictionary

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO `deroff(1)`, `eqn(1)`, `sort(1)`, `tbl(1)`, `troff(1)`, `attributes(5)`, `environ(5)`

NOTES Misspelled words can be monitored by default by setting the `H_SPELL` variable in `/usr/bin/spell` to the name of a file that has permission mode 666.

`spell` works only on English words defined in the U.S. ASCII codeset.

Because copies of all output are accumulated in the `spellhist` file, `spellhist` may grow quite large and require purging.

spell(1)

BUGS | The spelling list's coverage is uneven; new installations may wish to monitor the output for several months to gather local additions.

British spelling was done by an American.

spline(1)

NAME	spline – interpolate smooth curve				
SYNOPSIS	spline [-aknpx] ...				
DESCRIPTION	spline takes pairs of numbers from the standard input as abscissas and ordinates of a function. It produces a similar set, which is approximately equally spaced and includes the input set, on the standard output. The cubic spline output (R. W. Hamming, <i>Numerical Methods for Scientists and Engineers</i> , 2nd ed., 349ff) has two continuous derivatives, and sufficiently many points to look smooth when plotted, for example by graph(1).				
OPTIONS	<p>-a Supply abscissas automatically (they are missing from the input); spacing is given by the next argument, or is assumed to be 1 if next argument is not a number.</p> <p>-k The constant k used in the boundary value computation <i>(2nd deriv. at end) = k*(2nd deriv. next to end)</i> is set by the next argument. By default $k = 0$.</p> <p>-n Space output points so that approximately n intervals occur between the lower and upper x limits. (Default $n = 100$.)</p> <p>-p Make output periodic, that is, match derivatives at ends. First and last input values should normally agree.</p> <p>-x Next 1 (or 2) arguments are lower (and upper) x limits. Normally these limits are calculated from the data. Automatic abscissas start at lower limit (default 0).</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWesu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWesu				
SEE ALSO	graph(1), attributes(5) R. W. Hamming, <i>Numerical Methods for Scientists and Engineers</i> , 2nd ed.				
DIAGNOSTICS	When data is not strictly monotonic in x , spline reproduces the input without interpolating extra points.				
BUGS	A limit of 1000 input points is enforced silently.				

NAME	split – split a file into pieces
SYNOPSIS	split [-linecount -l <i>linecount</i>] [-a <i>suffixlength</i>] [<i>file</i> [<i>name</i>]] split [-b <i>n</i> <i>nk</i> <i>nm</i>] [-a <i>suffixlength</i>] [<i>file</i> [<i>name</i>]]
DESCRIPTION	The <code>split</code> utility reads <i>file</i> and writes it in <i>linecount</i> -line pieces into a set of output-files. The name of the first output-file is <i>name</i> with <code>aa</code> appended, and so on lexicographically, up to <code>zz</code> (a maximum of 676 files). The maximum length of <i>name</i> is 2 characters less than the maximum filename length allowed by the filesystem. See <code>statvfs(2)</code> . If no output name is given, <code>x</code> is used as the default (output-files will be called <code>xaa</code> , <code>xab</code> , and so forth).
OPTIONS	The following options are supported: <i>-linecount</i> -l <i>linecount</i> Number of lines in each piece. Defaults to 1000 lines. -i <i>suffixlength</i> Uses <i>suffixlength</i> letters to form the suffix portion of the filenames of the split file. If -a is not specified, the default suffix length is 2. If the sum of the <i>name</i> operand and the <i>suffixlength</i> option-argument would create a filename exceeding <code>NAME_MAX</code> bytes, an error will result; <code>split</code> will exit with a diagnostic message and no files will be created. -b <i>n</i> Splits a file into pieces <i>n</i> bytes in size. -b <i>nk</i> Splits a file into pieces <i>n</i> *1024 bytes in size. -b <i>nm</i> Splits a file into pieces <i>n</i> *1 048 576 bytes in size.
OPERANDS	The following operands are supported: <i>file</i> The path name of the ordinary file to be split. If no input file is given or <i>file</i> is <code>-</code> , the standard input will be used. <i>name</i> The prefix to be used for each of the files resulting from the <code>split</code> operation. If no <i>name</i> argument is given, <code>x</code> will be used as the prefix of the output files. The combined length of the basename of <i>prefix</i> and <i>suffixlength</i> cannot exceed <code>NAME_MAX</code> bytes. See OPTIONS .
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>split</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>split</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

split(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Interface Stability	Standard

SEE ALSO `csplit(1)`, `statvfs(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

NAME	srchtxt – display contents of, or search for a text string in, message data bases
SYNOPSIS	srchtxt [-s] [-l <i>locale</i>] [-m <i>msgfile</i> ,...] [<i>text</i>]
DESCRIPTION	<p>The <i>srchtxt</i> utility is used to display all the text strings in message data bases, or to search for a text string in message data bases (see <i>mkmsgs(1)</i>). These data bases are files in the directory <code>/usr/lib/locale/locale/LC_MESSAGES</code> (see <i>setlocale(3C)</i>), unless a file name given with the <code>-m</code> option contains a <code>/</code>. The directory <i>locale</i> can be viewed as the name of the language in which the text strings are written. If the <code>-l</code> option is not specified, the files accessed will be determined by the value of the environment variable <code>LC_MESSAGES</code>. If <code>LC_MESSAGES</code> is not set, the files accessed will be determined by the value of the environment variable <code>LANG</code>. If <code>LANG</code> is not set, the files accessed will be in the directory <code>/usr/lib/locale//C/LC_MESSAGES</code>, which contains default strings.</p> <p>If no <i>text</i> argument is present, then all the text strings in the files accessed will be displayed.</p> <p>If the <code>-s</code> option is not specified, the displayed text is prefixed by message sequence numbers. The message sequence numbers are enclosed in angle brackets: <code><msgfile:msgnum></code>.</p> <p><i>msgfile</i> name of the file where the displayed text occurred</p> <p><i>msgnum</i> sequence number in <i>msgfile</i> where the displayed text occurred</p> <p>This display is in the format used by <i>gettext(1)</i> and <i>gettext(3C)</i>.</p>
OPTIONS	<p><code>-s</code> Suppress printing of the message sequence numbers of the messages being displayed.</p> <p><code>-l locale</code> Access files in the directory <code>/usr/lib/locale/locale/LC_MESSAGES</code>. If <code>-m msgfile</code> is also supplied, <code>LOCALE</code> is ignored for <i>msgfiles</i> containing a <code>/</code>.</p> <p><code>-m msgfile</code> Access files specified by one or more <i>msgfiles</i>. If <i>msgfile</i> contains a <code>/</code> character, then <i>msgfile</i> is interpreted as a pathname; otherwise, it will be assumed to be in the directory determined as described above. To specify more than one <i>msgfile</i>, separate the file names using commas.</p> <p><i>text</i> Search for the text string specified by <i>text</i> and display each one that matches. <i>text</i> can take the form of a regular expression; see <i>regex(5)</i>.</p>
EXAMPLES	<p>EXAMPLE 1 Using <i>srchtxt</i></p> <p>If message files have been installed in a locale named <i>french</i> by using <i>mkmsgs(1)</i>, then you could display the entire set of text strings in the <i>french</i> locale (<code>/usr/lib/locale/french/LC_MESSAGES/*</code>) by typing:</p> <pre>example% srchtxt -l french</pre>

srchtxt(1)

EXAMPLE 1 Using srchtxt (Continued)

EXAMPLE 2 Using srchtxt

If a set of error messages associated with the operating system have been installed in the file UX in the french locale (/usr/lib/locale/french/LC_MESSAGE/UX), then, using the value of the LANG environment variable to determine the locale to be searched, you could search that file in that locale for all error messages dealing with files by typing:

```
example% setenv LANG=french; export LANG
example% srchtxt -m UX "[Ff]ichier"
```

If /usr/lib/locale/french/LC_MESSAGES/UX contained the following strings:

```
Erreur E/S\n
Liste d'arguments trop longue\n
Fichier inexistant\n
Argument invalide\n
Trop de fichiers ouverts\n
Fichier trop long\n
Trop de liens\n
Argument hors du domaine\n
Identificateur supprim\n
Etreinte fatale\n
.\n
.\n
.
```

then the following strings would be displayed:

```
<UX:3>Fichier inexistant\n
<UX:5>Trop de fichiers ouverts\n
<UX:6>Fichier trop long\n
```

EXAMPLE 3 Using srchtxt

If a set of error messages associated with the operating system have been installed in the file UX and a set of error messages associated with the INGRESS data base product have been installed in the file ingress, both in the german locale, then you could search for the pattern [Dd]atei in both the files UX and ingress in the german locale by typing:

```
example% srchtxt -l german -m UX,ingress "[Dd]atei"
```

ENVIRONMENT VARIABLES

See environ(5) for a description of the LC_CTYPE environment variable that affects the execution of srchtxt.

FILES

/usr/lib/locale/C/LC_MESSAGES/*
default files created by mkmsgs(1)

/usr/lib/locale/locale/LC_MESSAGES/*
message files created by mkmsgs(1)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc

SEE ALSO `exstr(1)`, `gettext(1)`, `locale(1)`, `mkmsgs(1)`, `gettext(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`, `locale(5)`, `regex(5)`

DIAGNOSTICS The error messages produced by `srchtxt` are intended to be self-explanatory. They indicate an error in the command line or errors encountered while searching for a particular locale and/or message file.

ssh(1)

NAME	ssh – OpenSSH secure shell client (remote login program)
SYNOPSIS	<pre>ssh [-l login_name] [hostname user@hostname] [command] ssh -afgknqtvxACNPTX246 [-c cipher_spec] [-e escape_char] [-i identity_file] [-l login_name] [-o option] [-p port] [-L port:host:hostport] [-R port:host:hostport] [hostname user@hostname] [command]</pre>
DESCRIPTION	<p>ssh (Secure Shell) is a program for logging into a remote machine and for executing commands on a remote machine. It is intended to replace rlogin and rsh, and to provide secure encrypted communications between two untrusted hosts over an insecure network. X11 connections and arbitrary TCP/IP ports can also be forwarded over the secure channel.</p> <p>ssh connects and logs into the specified hostname. The user must prove his or her identity to the remote machine using one of several methods depending on the protocol version used:</p>
SSH protocol version 1	<p>First, if the machine the user logs in from is listed in /etc/hosts.equiv or /etc/shosts.equiv on the remote machine, and the user names are the same on both sides, the user is immediately permitted to log in. Second, if .rhosts or .shosts exists in the user's home directory on the remote machine and contains a line containing the name of the client machine and the name of the user on that machine, the user is permitted to log in. This form of authentication alone is normally not allowed by the server because it is not secure.</p> <p>The second (and primary) authentication method is the rhosts or hosts.equiv method combined with RSA-based host authentication. It means that if the login would be permitted by \$HOME/.rhosts, \$HOME/.shosts, /etc/hosts.equiv, or /etc/shosts.equiv, and if additionally the server can verify the client's host key (see /etc/ssh_known_hosts in the FILES section), only then is login permitted. This authentication method closes security holes due to IP spoofing, DNS spoofing, and routing spoofing.</p> <p>Note to the administrator: /etc/hosts.equiv, \$HOME/.rhosts, and the rlogin/rsh protocol in general, are inherently insecure and should be disabled if security is desired.</p> <p>As a third authentication method, ssh supports RSA-based authentication. The scheme is based on public-key cryptography. There are cryptosystems where encryption and decryption are done using separate keys, and it is not possible to derive the decryption key from the encryption key. RSA is one such system. The idea is that each user creates a public/private key pair for authentication purposes. The server knows the public key, and only the user knows the private key. The file \$HOME/.ssh/authorized_keys lists the public keys that are permitted for logging in. When the user logs in, the ssh program tells the server which key pair it would like to use for authentication. The server checks if this key is permitted, and if so, sends the user (actually the ssh program running on behalf of the user) a challenge in</p>

the form of a random number, encrypted by the user's public key. The challenge can only be decrypted using the proper private key. The user's client then decrypts the challenge using the private key, proving that he or she knows the private key but without disclosing it to the server.

ssh implements the RSA authentication protocol automatically. The user creates his or her RSA key pair by running `ssh-keygen(1)`. This stores the private key in `$HOME/.ssh/identity` and the public key in `$HOME/.ssh/identity.pub` in the user's home directory. The user should then copy the `identity.pub` to `$HOME/.ssh/authorized_keys` in his or her home directory on the remote machine (the `authorized_keys` file corresponds to the conventional `$HOME/.rhosts` file, and has one key per line, though the lines can be very long). After this, the user can log in without giving the password. RSA authentication is much more secure than `rhosts` authentication.

The most convenient way to use RSA authentication may be with an authentication agent. See `ssh-agent(1)` for more information.

If other authentication methods fail, `ssh` prompts the user for a password. The password is sent to the remote host for checking. However, since all communications are encrypted, the password cannot be seen by someone listening on the network.

SSH protocol version 2

When a user connects using the protocol version 2, different authentication methods are available. At first, the client attempts to authenticate using the public key method. If this method fails, password authentication is tried.

The public key method is similar to RSA authentication described in the previous section except that the DSA algorithm is used instead of the patented RSA algorithm. The client uses his private DSA key `$HOME/.ssh/id_dsa` to sign the session identifier and sends the result to the server. The server checks whether the matching public key is listed in `$HOME/.ssh/authorized_keys` and grants access if both the key is found and the signature is correct. The session identifier is derived from a shared Diffie-Hellman value and is known only to the client and the server.

If public key authentication fails or is not available, a password can be sent encrypted to the remote host for proving the user's identity. This protocol 2 implementation does not yet support Kerberos or S/Key authentication.

Protocol 2 provides additional mechanisms for confidentiality (the traffic is encrypted using 3DES, Blowfish, CAST128 or Arcfour) and integrity (`hmac-sha1`, `hmac-md5`). Notice that protocol 1 lacks a strong mechanism for ensuring the integrity of the connection.

Login session and remote execution

When the user's identity has been accepted by the server, the server either executes the given command, or logs into the machine and gives the user a normal shell on the remote machine. All communication with the remote command or shell will be automatically encrypted.

ssh(1)

If a pseudo-terminal has been allocated (normal login session), the user can disconnect with `~.`, and suspend `ssh` with `~^Z`. All forwarded connections can be listed with `~#`. If the session blocks waiting for forwarded X11 or TCP/IP connections to terminate, `ssh` can be backgrounded with `~&`, although this should not be used while the user shell is active, as it can cause the shell to hang. All available escapes can be listed with `~?`.

A single tilde character can be sent as `~~` (or by following the tilde by a character other than those described above). The escape character must always follow a newline to be interpreted as special. The escape character can be changed in configuration files or on the command line.

If no pseudo tty has been allocated, the session is transparent and can be used to reliably transfer binary data. On most systems, setting the escape character to "none" will also make the session transparent even if a tty is used.

The session terminates when the command or shell in the remote machine exits and all X11 and TCP/IP connections have been closed. The exit status of the remote program is returned as the exit status of `ssh`.

X11 and TCP forwarding

If the user is using X11 (the `DISPLAY` environment variable is set), the connection to the X11 display is automatically forwarded to the remote side in such a way that any X11 programs started from the shell (or command) will go through the encrypted channel, and the connection to the real X server will be made from the local machine. The user should not manually set `DISPLAY`. Forwarding of X11 connections can be configured on the command line or in configuration files.

The `DISPLAY` value set by `ssh` will point to the server machine, but with a display number greater than zero. This is normal behavior, because `ssh` creates a "proxy" X server on the server machine for forwarding the connections over the encrypted channel.

`ssh` will also automatically set up Xauthority data on the server machine. For this purpose, it will generate a random authorization cookie, store it in Xauthority on the server, and verify that any forwarded connections carry this cookie and replace it by the real cookie when the connection is opened. The real authentication cookie is never sent to the server machine (and no cookies are sent in the plain).

If the user is using an authentication agent, the connection to the agent is automatically forwarded to the remote side unless disabled on the command line or in a configuration file.

Forwarding of arbitrary TCP/IP connections over the secure channel can be specified either on the command line or in a configuration file. One possible application of TCP/IP forwarding is a secure connection to an electronic purse. Another possible application is going through firewalls.

Server authentication

`ssh` automatically maintains and checks a database containing identifications for all hosts it has ever been used with. RSA host keys are stored in `$HOME/.ssh/known_hosts` in the user's home directory. Additionally, the file

`/etc/ssh_known_hosts` is automatically checked for known hosts. Any new hosts are automatically added to the user's file. If a host's identification ever changes, `ssh` warns about this and disables password authentication to prevent a trojan horse from getting the user's password. Another purpose of this mechanism is to prevent man-in-the-middle attacks which could otherwise be used to circumvent the encryption. The `StrictHostKeyChecking` option (see below) can be used to prevent logins to machines whose host key is not known or has changed.

OPTIONS

The following options are supported:

- 2
Forces `ssh` to try protocol version 2 only.
- 4
Forces `ssh` to use IPv4 addresses only.
- 6
Forces `ssh` to use IPv6 addresses only.
- a
Disables forwarding of the authentication agent connection.
- A
Enables forwarding of the authentication agent connection. This can also be specified on a per-host basis in a configuration file.
- c `blowfish | 3des`
Selects the cipher to use for encrypting the session. `3des` is used by default. It is believed to be secure. `3des` (triple-des) is an encrypt-decrypt-encrypt triple with three different keys. It is presumably more secure than the `des` cipher, which is no longer fully supported in `ssh`. `blowfish` is a fast block cipher, it appears very secure and is much faster than `3des`.
- c `3des-cbc,blowfish-cbc,aes128-cbc`
Additionally, for protocol version 2 a comma-separated list of ciphers can be specified in order of preference. Protocol version 2 supports 3DES, Blowfish, and AES 128 in CBC mode.
- C
Requests compression of all data (including `stdin`, `stdout`, `stderr`, and data for forwarded X11 and TCP/IP connections). The compression algorithm is the same used by `gzip(1)`. (The `gzip` man page is available in the `SUNWsfman` package.) The "level" can be controlled by the `CompressionLevel` option (see below). Compression is desirable on modem lines and other slow connections, but will only slow down things on fast networks. The default value can be set on a host-by-host basis in the configuration files. See the `Compress` option below.
- e `ch | ^ch | none`
Sets the escape character for sessions with a pty (default: `'~'`). The escape character is only recognized at the beginning of a line. The escape character followed by a dot ("`."`") closes the connection. If followed by control-Z, the escape character suspends

ssh(1)

the connection. If followed by itself, the escape character sends itself once. Setting the character to "none" disables any escapes and makes the session fully transparent.

-f

Requests `ssh` to go to background just before command execution. This is useful if `ssh` is going to ask for passwords or passphrases, but the user wants it in the background. This implies the `-n` option. The recommended way to start X11 programs at a remote site is with something like `ssh -f host xterm`.

-g

Allows remote hosts to connect to local forwarded ports.

-i *identity_file*

Selects the file from which the identity (private key) for RSA authentication is read. Default is `$HOME/.ssh/identity` in the user's home directory. Identity files may also be specified on a per-host basis in the configuration file. It is possible to have multiple `-i` options (and multiple identities specified in configuration files).

-l *login_name*

Specifies the user to log in as on the remote machine. This also may be specified on a per-host basis in the configuration file.

-L *port:host:hostport*

Specifies that the given port on the local (client) host is to be forwarded to the given host and port on the remote side. This works by allocating a socket to listen to the port on the local side. Then, whenever a connection is made to this port, the connection is forwarded over the secure channel and a connection is made to *host port hostport* from the remote machine. Port forwardings can also be specified in the configuration file. Only root can forward privileged ports. IPv6 addresses can be specified with an alternative syntax: *port/host/hostport*.

-n

Redirects stdin from `/dev/null` (actually, prevents reading from stdin). This must be used when `ssh` is run in the background. A common trick is to use this to run X11 programs on a remote machine. For example,

```
ssh -n shadows.cs.hut.fi emacs &
```

will start an `emacs` on `shadows.cs.hut.fi`, and the X11 connection will be automatically forwarded over an encrypted channel. The `ssh` program will be put in the background. This does not work if `ssh` needs to ask for a password or passphrase. See also the `-f` option.)

-N

Does not execute a remote command. This is useful if you just want to forward ports (protocol version 2 only).

-o *option*

Can be used to give options in the format used in the configuration file. This is useful for specifying options for which there is no separate command-line flag. The option has the same format as a line in the configuration file.

- p *port*
Specifies the port to connect to on the remote host. This can be specified on a per-host basis in the configuration file.
- P
Uses a non-privileged port for outgoing connections. This can be used if your firewall does not permit connections from privileged ports. Notice that this option turns off `RhostsAuthentication` and `RhostsRSAAuthentication`.
- q
Quiet mode. Causes all warning and diagnostic messages to be suppressed. Only fatal errors are displayed.
- R *port:host:hostport*
Specifies that the given port on the remote (server) host is to be forwarded to the given host and port on the local side. This works by allocating a socket to listen to the port on the remote side. Then, whenever a connection is made to this port, the connection is forwarded over the secure channel and a connection is made to *host port hostport* from the local machine. Port forwardings can also be specified in the configuration file. Privileged ports can be forwarded only when logging in as root on the remote machine.
- t
Forces pseudo-tty allocation. This can be used to execute arbitrary screen-based programs on a remote machine, which can be very useful, for example, when implementing menu services.
- T
Disables pseudo-tty allocation (protocol version 2 only).
- v
Verbose mode. Causes `ssh` to print debugging messages about its progress. This is helpful in debugging connection, authentication, and configuration problems. Multiple `-v` options increase the verbosity. Maximum is 3.
- x
Disables X11 forwarding.
- X
Enables X11 forwarding. This can also be specified on a per-host basis in a configuration file.

ENVIRONMENT VARIABLES

`ssh` will normally set the following environment variables:

DISPLAY The `DISPLAY` variable indicates the location of the X11 server. It is automatically set by `ssh` to point to a value of the form *hostname:n* where *hostname* indicates the host where the shell runs, and *n* is an integer greater than or equal to 1. `ssh` uses this special value to forward X11 connections over the secure channel. The user should normally not set `DISPLAY` explicitly, as that will render the X11 connection insecure (and will require the user to manually copy any required authorization cookies).

ssh(1)

HOME	Set to the path of the user's home directory.
LOGNAME	Synonym for USER. Set for compatibility with systems that use this variable.
MAIL	Set to point to the user's mailbox.
PATH	Set to the default PATH, as specified when compiling ssh.
SSH_AUTH_SOCK	Indicates the path of a unix-domain socket used to communicate with the agent.
SSH_CLIENT	Identifies the client end of the connection. The variable contains three space-separated values: client ip-address, client port number, and server port number.
SSH_TTY	This is set to the name of the tty (path to the device) associated with the current shell or command. If the current session has no tty, this variable is not set.
TZ	The timezone variable is set to indicate the present timezone if it was set when the daemon was started, that is, the daemon passes the value on to new connections.
USER	Set to the name of the user logging in.

Additionally, ssh reads `$HOME/.ssh/environment` and adds lines of the format `VARIABLE=value` to the environment

EXIT STATUS The following exit values are returned:

0	Successful completion.
1	An error occurred.

FILES

`$HOME/.ssh/known_hosts`
Records host keys for all hosts the user has logged into that are not in `/etc/ssh_known_hosts`. See `sshd(1M)`.

`$HOME/.ssh/identity`
`$HOME/.ssh/id_dsa`
Contains the RSA and the DSA authentication identity of the user. These files contain sensitive data and should be readable by the user but not accessible by others (read/write/execute). Notice that ssh ignores a private key file if it is accessible by others. It is possible to specify a passphrase when generating the key. The passphrase will be used to encrypt the sensitive part of this file using 3DES.

`$HOME/.ssh/identity.pub`
`$HOME/.ssh/id_dsa.pub`
Contains the public key for authentication, that is, the public part of the identity file in human-readable form. The contents of the `$HOME/.ssh/identity.pub` file should be added to `$HOME/.ssh/authorized_keys` on all machines where you wish to log in using RSA authentication. The contents of the `$HOME/.ssh/id_dsa.pub` file should be added to

`$HOME/.ssh/authorized_keys` on all machines where you wish to log in using DSA authentication. These files are not sensitive and can, but need not, be readable by anyone. These files are never used automatically and are not necessary. They are provided only for the convenience of the user.

`$HOME/.ssh/config`

This is the per-user configuration file. The format of this file is described above.

This file is used by the `ssh` client. This file does not usually contain any sensitive information, but the recommended permissions are read/write for the user and not accessible by others.

`$HOME/.ssh/authorized_keys`

Lists the DSA keys that can be used for logging in as this user. This file is not highly sensitive, but the recommended permissions are read/write for the user and not accessible by others.

`/etc/ssh/ssh_known_hosts`

Systemwide list of known host keys. `/etc/ssh/ssh_known_hosts` contains RSA keys. This file should be prepared by the system administrator to contain the public host keys of all machines in the organization and should be world-readable. The file contains public keys, one per line, in the following format, with fields separated by spaces: system name, number of bits in modulus, public exponent, modulus, and optional comment field. When different names are used for the same machine, all such names should be listed, separated by commas. See `sshd(1M)`.

The canonical system name (as returned by name servers) is used by `sshd(1M)` to verify the client host when logging in. Other names are needed because `ssh` does not convert the user-supplied name to a canonical name before checking the key, to prevent someone with access to the name servers from being able to fool host authentication.

`/etc/ssh/ssh_config`

Systemwide configuration file. This file provides defaults for those values that are not specified in the user's configuration file, and for those users who do not have a configuration file.

This file must be world-readable.

`$HOME/.rhosts`

This file is used in `.rhosts` authentication to list the host/user pairs that are permitted to log in. (Notice that this file is also used by `rlogin` and `rsh`, which makes using this file insecure.) Each line of the file contains a host name (in the canonical form returned by name servers), and then a user name on that host, separated by a space. On some machines, this file may need to be world-readable if the user's home directory is on an NFS partition, because `sshd(1M)` reads it as root. Additionally, this file must be owned by the user and must not have write permissions for anyone else. The recommended permission for most machines is read/write for the user and not accessible by others.

ssh(1)

Notice that, by default, `sshd(1M)` will be installed so that it requires successful RSA host authentication before permitting `.rhosts` authentication. If your server machine does not have the client's host key in `/etc/ssh_known_hosts`, you can store it in `$HOME/.ssh/known_hosts`. The easiest way to do this is to connect back to the client from the server machine using `ssh`. This will automatically add the host key to `$HOME/.ssh/known_hosts`.

`$HOME/.shosts`

This file is used exactly the same way as `.rhosts`. The purpose for having this file is to be able to use `rhosts` authentication with `ssh` without permitting login with `rlogin(1)` or `rsh(1)`.

`/etc/hosts.equiv`

This file is used during `.rhosts` authentication. It contains canonical hosts names, one per line. (See `sshd(1M)` for the full format description.) If the client host is found in this file, login is automatically permitted, provided that client and server user names are the same. In addition, successful RSA host authentication is normally required. This file should only be writable by root.

`/etc/ssh/shosts.equiv`

This file is processed exactly as `/etc/hosts.equiv`. This file may be useful to permit logins using `ssh` but not using `rsh` or `rlogin`.

`/etc/ssh/sshr`

Commands in this file are executed by `ssh` when the user logs in just before the user's shell or command is started. See `sshd(1M)` for more information.

`$HOME/.ssh/rc`

Commands in this file are executed by `ssh` when the user logs in just before the user's shell or command is started. See `sshd(1M)` for more information.

`$HOME/.ssh/environment`

Contains additional definitions for environment variables. See `ENVIRONMENT VARIABLES`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ssh-add(1)

NAME	ssh-add – add RSA or DSA identities for the authentication agent
SYNOPSIS	ssh-add [-lLdD] [<i>file</i> ...]
DESCRIPTION	<p>The <code>ssh-add</code> utility adds RSA or DSA identities to the authentication agent, <code>ssh-agent(1)</code>. When run without arguments, it attempts to add all of the files <code>\$HOME/.ssh/identity</code> (RSA v1), <code>\$HOME/.ssh/id_rsa</code> (RSA v2), and <code>\$HOME/.ssh/id_dsa</code> (DSA v2) that exist. If more than one of the private keys exists, an attempt to decrypt each with the same passphrase will be made before reprompting for a different passphrase. The passphrase is read from the user's tty or by running the program defined in <code>SSH_ASKPASS</code> (see below).</p> <p>The authentication agent must be running.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-d Instead of adding the identity, this option <i>removes</i> the identity from the agent.-D Deletes all identities from the agent.-l Lists fingerprints of all identities currently represented by the agent.-L Lists public key parameters of all identities currently represented by the agent.
ENVIRONMENT VARIABLES	<p><code>DISPLAY</code> <code>SSH_ASKPASS</code> If <code>ssh-add</code> needs a passphrase, it will read the passphrase from the current terminal if it was run from a terminal. If <code>ssh-add</code> does not have a terminal associated with it but <code>DISPLAY</code> and <code>SSH_ASKPASS</code> are set, it will execute the program specified by <code>SSH_ASKPASS</code> and open an X11 window to read the passphrase. This is particularly useful when calling <code>ssh-add</code> from a <code>.Xsession</code> or related script.</p>
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none">0 Successful completion.1 An error occurred.
FILES	<p>These files should not be readable by anyone but the user. Notice that <code>ssh-add</code> ignores a file if it is accessible by others. It is possible to specify a passphrase when generating the key; that passphrase will be used to encrypt the private part of this file.</p> <p>If these files are stored on a network file system it is assumed that either the protection provided in the file themselves or the transport layer of the network file system provides sufficient protection for the site policy. If this is not the case, then it is recommended the key files are stored on removable media or locally on the relevant hosts.</p> <p>Recommended names for the DSA and RSA key files:</p>

<code>\$HOME/.ssh/identity</code>	Contains the RSA authentication identity of the user for protocol version 1.
<code>\$HOME/.ssh/identity.pub</code>	Contains the public part of the RSA authentication identity of the user for protocol version 1.
<code>\$HOME/.ssh/id_dsa</code>	Contains the private DSA authentication identity of the user.
<code>\$HOME/.ssh/id_dsa.pub</code>	Contains the public part of the DSA authentication identity of the user.
<code>\$HOME/.ssh/id_rsa</code>	Contains the private RSA authentication identity of the user.
<code>\$HOME/.ssh/id_rsa.pub</code>	Contains the public part of the RSA authentication identity of the user.

ssh-agent(1)

NAME	ssh-agent – authentication agent
SYNOPSIS	ssh-agent [-c -s] [-k] [<i>command</i> [<i>args...</i>]]
DESCRIPTION	<p>ssh-agent is a program to hold private keys used for public key authentication (RSA, DSA). ssh-agent is often started at the beginning of a login session. All other windows or programs are started as clients to the ssh-agent program. Through use of environment variables, the agent can be located and automatically used for authentication when logging in to other machines using ssh(1). (See <i>System Administration Guide: Security Services</i>.)</p> <p>If a command line is given, this is executed as a subprocess of the agent. When the command dies, so does the agent.</p> <p>The agent initially does not have any private keys. Keys are added using ssh-add(1), which sends the identity to the agent. Several identities can be stored in the agent; the agent can automatically use any of these identities. Use the -l option in ssh-add(1) to display the identities currently held by the agent.</p> <p>The agent is run in the user's local host. Authentication data need not be stored on any other machine, and authentication passphrases never go over the network. However, if the connection to the agent is forwarded over SSH remote logins, the user can use the privileges given by the identities anywhere in the network in a secure way.</p> <p>There are two main ways to get an agent setup. Either you let the agent start a new subcommand into which some environment variables are exported, or you let the agent print the needed shell commands (either sh(1) or csh(1) syntax can be generated) which can be eval'd in the calling shell. Later, use ssh(1) to look at these variables and use them to establish a connection to the agent.</p> <p>A unix-domain socket is created (/tmp/ssh-XXXXXXX/agent.<i>pid</i>) and the name of this socket is stored in the SSH_AUTH_SOCK environment variable. The socket is made accessible only to the current user. This method is easily abused by root or another instance of the same user.</p> <p>The SSH_AGENT_PID environment variable holds the agent's PID.</p> <p>The agent exits automatically when the command given on the command line terminates.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-c Generates C-shell commands on stdout. This is the default if SHELL indicates that it is a csh style of shell.-k Kills the current agent (given by the SSH_AGENT_PID environment variable)-s Generates Bourne shell commands on stdout. This is the default if SHELL does not indicate that it is a csh style of shell.
EXIT STATUS	The following exit values are returned:

0 Successful completion.

1 An error occurred.

FILES /tmp/ssh-XXXXXXXX/agent.pid

Unix-domain sockets used to contain the connection to the authentication agent. These sockets should only be readable by the owner. The sockets are removed when the agent exits.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ssh-http-proxy-connect(1)

NAME	ssh-http-proxy-connect – Secure Shell proxy for HTTP
SYNOPSIS	<code>/usr/lib/ssh/ssh-http-proxy-connect [-h <i>http_proxy_host</i>] [-p <i>http_proxy_port</i>] <i>connect_host</i> <i>connect_port</i></code>
DESCRIPTION	A proxy command for <code>ssh(1)</code> that uses HTTP CONNECT. Typical use is where connections external to a network are only allowed via a proxy web server.
OPTIONS	The following options are supported: <code>-h <i>http_proxy_host</i></code> Specifies the proxy web server through which to connect. Overrides the <code>HTTPPROXY</code> and <code>http_proxy</code> environment variables if they are set. <code>-p <i>http_proxy_port</i></code> Specifies the port on which the proxy web server runs. If not specified, port 80 is assumed. Overrides the <code>HTTPPROXYPORT</code> and <code>http_proxy</code> environment variables if they are set.
OPERANDS	The following operands are supported: <code><i>http_proxy_host</i></code> The host name or IP address (IPv4 or IPv6) of the proxy. <code><i>http_proxy_port</i></code> The numeric port number to connect to on <code><i>http_proxy_host</i></code> . <code><i>connect_host</i></code> The name of the remote host to which the proxy web server is to connect you. <code><i>connect_port</i></code> The numeric port number of the proxy web server to connect you to on <code><i>http_proxy_host</i></code> .
EXAMPLES	The recommended way to use a proxy connection command is to configure the <code>ProxyCommand</code> in <code>ssh_config(4)</code> (see Example 1 and Example 2). Example 3 shows how the proxy command can be specified on the command line when running <code>ssh(1)</code> . EXAMPLE 1 Setting the proxy from the environment The following example uses <code>ssh-http-proxy-connect</code> in <code>ssh_config(4)</code> when the proxy is set from the environment: <pre>Host playtime.foo.com ProxyCommand /usr/lib/ssh/ssh-http-proxy-connect \ playtime.foo.com 22</pre> EXAMPLE 2 Overriding proxy environment variables The following example uses <code>ssh-http-proxy-connect</code> in <code>ssh_config(4)</code> to override (or if not set) proxy environment variables: <pre>Host playtime.foo.com ProxyCommand /usr/lib/ssh/ssh-http-proxy-connect -h webcache \</pre>

EXAMPLE 2 Overriding proxy environment variables (Continued)

```
-p 8080 playtime.foo.com 22
```

EXAMPLE 3 Using the command line

The following example uses `ssh-http-proxy-connect` from the `ssh(1)` command line:

```
example$ ssh -o'ProxyCommand="/usr/lib/ssh/ssh-http-proxy-connect \  
-h webcache -p 8080 playtime.foo.com 22"' playtime.foo.com
```

ENVIRONMENT VARIABLES

HTTPPROXY Takes the `http_proxy_host` operand to specify the default proxy host. Overrides `http_proxy` if both are set.

HTTPPROXYPORT Takes the `http_proxy_port` operand to specify the default proxy port. Ignored if **HTTPPROXY** is not set.

http_proxy URL format for specifying proxy host and port.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

1 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ssh-keygen(1)

NAME	ssh-keygen – authentication key generation
SYNOPSIS	ssh-keygen [-q] [-t <i>type</i>] [-b <i>bits</i>] [-N <i>new_passphrase</i>] [-C <i>comment</i>] [-f <i>output_keyfile</i>] ssh-keygen -p [-P <i>old_passphrase</i>] [-N <i>new_passphrase</i>] [-f <i>keyfile</i>] ssh-keygen -x [-f <i>input_keyfile</i>] ssh-keygen -X [-f <i>input_keyfile</i>] ssh-keygen -y [-f <i>input_keyfile</i>] ssh-keygen -c [-P <i>passphrase</i>] [-C <i>comment</i>] [-f <i>keyfile</i>] ssh-keygen -l [-f <i>input_keyfile</i>]
DESCRIPTION	<p>The <code>ssh-keygen</code> utility generates and manages authentication keys for <code>ssh(1)</code>. <code>ssh-keygen</code> defaults to generating an RSA key for use by protocol 2.0.</p> <p>Each user wishing to use SSH with RSA or DSA authentication normally runs this once to create the authentication key in <code>\$HOME/.ssh/identity</code> or <code>\$HOME/.ssh/id_dsa</code>. The system administrator may also use this to generate host keys.</p> <p>Ordinarily, this program generates the key and asks for a file in which to store the private key. The public key is stored in a file with the same name but with the “.pub” extension appended. The program also asks for a passphrase. The passphrase may be empty to indicate no passphrase (host keys must have empty passphrases), or it may be a string of arbitrary length. Good passphrases are 10-30 characters long and are not simple sentences or otherwise easy to guess. (English prose has only 1-2 bits of entropy per word, and provides very poor passphrases.) The passphrase can be changed later by using the <code>-p</code> option.</p> <p>There is no way to recover a lost passphrase. If the passphrase is lost or forgotten, you will have to generate a new key and copy the corresponding public key to other machines.</p> <p>For RSA, there is also a comment field in the key file that is only for convenience to the user to help identify the key. The <i>comment</i> can tell what the key is for, or whatever is useful. The comment is initialized to “<code>user@host</code>” when the key is created, but can be changed using the <code>-c</code> option.</p> <p>After a key is generated, instructions below detail where to place the keys to activate them.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-b <i>bits</i></code> Specifies the number of bits in the key to create. The minimum number is 512 bits. Generally, 1024 bits is considered sufficient. Key sizes above that no longer improve security but make things slower. The default is 1024 bits.</p>

-c	Requests changing the comment in the private and public key files. The program will prompt for the file containing the private keys, for the passphrase if the key has one, and for the new comment.
-C <i>comment</i>	Provides the new comment.
-f	Specifies the filename of the key file.
-l	Shows the fingerprint of the specified private or public key file.
-N <i>new_passphrase</i>	Provides the new passphrase.
-p	Requests changing the passphrase of a private key file instead of creating a new private key. The program will prompt for the file containing the private key, for the old passphrase, and will prompt twice for the new passphrase.
-P <i>passphrase</i>	Provides the (old) passphrase.
-q	Silences ssh-keygen. Used by <code>/etc/rc</code> when creating a new key.
-t <i>type</i>	Specifies the algorithm used for the key, where <i>type</i> is one of <code>rsa</code> , <code>dsa</code> , and <code>rsa1</code> . Type <code>rsa1</code> is used only for the SSHv1 protocol.
-x	Reads a private OpenSSH DSA format file and prints an SSH2-compatible public key to stdout.
-X	Reads an unencrypted SSH2-compatible private (or public) key file and prints an OpenSSH compatible private (or public) key to stdout.
-y	Reads a private OpenSSH DSA format file and prints an OpenSSH DSA public key to stdout.

EXIT STATUS The following exit values are returned:

0	Successful completion.
1	An error occurred.

FILES

`$HOME/.ssh/identity`

This file contains the RSA private key for the SSHv1 protocol. This file should not be readable by anyone but the user. It is possible to specify a passphrase when generating the key; that passphrase will be used to encrypt the private part of this file using 3DES. This file is not automatically accessed by `ssh-keygen`, but it is offered as the default file for the private key. `sshd(1M)` will read this file when a login attempt is made.

`$HOME/.ssh/identity.pub`

This file contains the RSA public key for the SSHv1 protocol. The contents of this file should be added to `$HOME/.ssh/authorized_keys` on all machines where you wish to log in using RSA authentication. There is no need to keep the contents of this file secret.

ssh-keygen(1)

`$HOME/.ssh/id_dsa`

`$HOME/.ssh/id_rsa`

These files contain, respectively, the DSA or RSA private key for the SSHv2 protocol. These files should not be readable by anyone but the user. It is possible to specify a passphrase when generating the key; that passphrase will be used to encrypt the private part of the file using 3DES. Neither of these files is automatically accessed by `ssh-keygen` but is offered as the default file for the private key. `sshd(1M)` will read this file when a login attempt is made.

`$HOME/.ssh/id_dsa.pub`

`$HOME/.ssh/id_rsa.pub`

These files contain, respectively, the DSA or RSA public key for the SSHv2 protocol. The contents of these files should be added, respectively, to `$HOME/.ssh/authorized_keys` on all machines where you wish to log in using DSA or RSA authentication. There is no need to keep the contents of these files secret.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

NAME	ssh-socks5-proxy-connect – Secure Shell proxy for SOCKS5
SYNOPSIS	<code>/usr/lib/ssh/ssh-socks5-proxy-connect [-h <i>socks5_proxy_host</i>] [-p <i>socks5_proxy_port</i>] <i>connect_host connect_port</i></code>
DESCRIPTION	<p>A proxy command for <code>ssh(1)</code> that uses SOCKS5 (RFC 1928). Typical use is where connections external to a network are only allowed via a socks gateway server.</p> <p>This proxy command does not provide any of the SOCKS5 authentication mechanisms defined in RFC 1928. Only anonymous connections are possible.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-h <i>socks5_proxy_host</i></code> Specifies the proxy web server through which to connect. Overrides the <code>SOCKS5_SERVER</code> environment variable.</p> <p><code>-p <i>socks5_proxy_port</i></code> Specifies the port on which the proxy web server runs. If not specified, port 80 is assumed. Overrides the <code>SOCKS5_PORT</code> environment variable.</p>
OPERANDS	<p>The following operands are supported:</p> <p><code><i>socks5_proxy_host</i></code> The host name or IP address (IPv4 or IPv6) of the proxy.</p> <p><code><i>socks5_proxy_port</i></code> The numeric port number to connect to on <code><i>socks5_proxy_host</i></code>.</p> <p><code><i>connect_host</i></code> The name of the remote host to which the socks gateway is to connect you.</p> <p><code><i>connect_port</i></code> The numeric port number of the socks gateway to connect you to on <code><i>connect_host</i></code>.</p>
EXAMPLES	<p>The recommended way to use a proxy connection command is to configure the <code>ProxyCommand</code> in <code>ssh_config(4)</code> (see Example 1 and Example 2). Example 3 shows how the proxy command can be specified on the command line when running <code>ssh(1)</code>.</p> <p>EXAMPLE 1 Setting the proxy from the environment</p> <p>The following example uses <code>ssh-socks5-proxy-connect</code> in <code>ssh_config(4)</code> when the proxy is set from the environment:</p> <pre>Host playtime.foo.com ProxyCommand /usr/lib/ssh/ssh-socks5-proxy-connect \ playtime.foo.com 22</pre> <p>EXAMPLE 2 Overriding proxy environment variables</p> <p>The following example uses <code>ssh-socks5-proxy-connect</code> in <code>ssh_config(4)</code> to override (or if not set) proxy environment variables:</p>

ssh-socks5-proxy-connect(1)

EXAMPLE 2 Overriding proxy environment variables (Continued)

```
Host playtime.foo.com
ProxyCommand /usr/lib/ssh/ssh-socks5-proxy-connect -h socks-gw \
-p 1080 -n 192.168.100.2 playtime.foo.com 22
```

EXAMPLE 3 Using the command line

The following example uses `ssh-socks5-proxy-connect` from the `ssh(1)` command line:

```
example$ ssh -o'ProxyCommand=/usr/lib/ssh/ssh-socks5-proxy-connect \
-h socks-gw -p 1080 playtime.foo.com 22' playtime.foo.com
```

ENVIRONMENT VARIABLES

`SOCKS5_SERVER` Takes `socks5_proxy_host` operand to specify the default proxy host.

`SOCKS5_PORT` Takes `socks5_proxy_port` operand to specify the default proxy port.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

1 An error occurred.

ATTRIBUTES

NAME	strchg, strconf – change or query stream configuration
SYNOPSIS	<pre> strchg -h <i>module1</i> [, <i>module2</i>...] strchg -p [-a -u <i>module</i>] strchg -f <i>filename</i> strconf [-m -t <i>module</i>] </pre>
DESCRIPTION	<p>These commands are used to alter or query the configuration of the stream associated with the user's standard input. The <code>strchg</code> command pushes modules on and/or pops modules off the stream. The <code>strconf</code> command queries the configuration of the stream. Only the super-user or owner of a STREAMS device may alter the configuration of that stream.</p> <p>Invoked without any arguments, <code>strconf</code> prints a list of all the modules in the stream as well as the topmost driver. The list is printed with one name per line where the first name printed is the topmost module on the stream (if one exists) and the last item printed is the name of the driver.</p>
OPTIONS	<p>The following options apply to <code>strchg</code> and, <code>-h</code>, <code>-f</code>, and <code>-p</code> are mutually exclusive.</p> <p><code>-h <i>module1</i> [, <i>module2</i>. . .]</code> Mnemonic for <i>push</i>, pushes modules onto a stream. It takes as arguments the names of one or more pushable streams modules. These modules are pushed in order; that is, <i>module1</i> is pushed first, <i>module2</i> is pushed second, etc.</p> <p><code>-p</code> Mnemonic for <i>pop</i>, pops modules off the stream. With the <code>-p</code> option alone, <code>strchg</code> pops the topmost module from the stream.</p> <p><code>-a <i>module</i></code> Pop all the modules above the topmost driver off the stream. This option requires the <code>-p</code> option.</p> <p><code>-u <i>module</i></code> All modules above, but not including <i>module</i> are popped off the stream. This option requires the <code>-p</code> option.</p> <p><code>-f <i>filename</i></code> Specify a <i>filename</i> that contains a list of modules representing the desired configuration of the stream. Each module name must appear on a separate line where the first name represents the topmost module and the last name represents the module that should be closest to the driver. <code>strchg</code> will determine the current configuration of the stream and pop and push the necessary modules in order to end up with the desired configuration.</p> <p>The following options apply to <code>strconf</code> and, <code>-m</code> and <code>-t</code> are mutually exclusive.</p> <p><code>-m <i>module</i></code> Determine if the named <i>module</i> is present on a stream. If it is, <code>strconf</code> prints the message <code>yes</code> and returns zero. If not,</p>

strchg(1)

`strconf` prints the message `no` and returns a non-zero value. The `-t` and `-m` options are mutually exclusive.

`-t module` Print only the topmost module (if one exists). The `-t` and `-m` options are mutually exclusive.

EXAMPLES **EXAMPLE 1** Using the `strchg` Command

The following command pushes the module `ldterm` on the stream associated with the user's standard input:

```
example% strchg -h ldterm
```

The following command pops the topmost module from the stream associated with `/dev/term/24`. The user must be the owner of this device or the super user.

```
example% strchg -p < /dev/term/24
```

If the file `fileconf` contains the following:

```
ttcompat
ldterm
ptem
then the command
```

```
example% strchg -f fileconf
```

will configure the user's standard input stream so that the module `ptem` is pushed over the driver, followed by `ldterm` and `ttcompat` closest to the stream head.

The `strconf` command with no arguments lists the modules and topmost driver on the stream; for a stream that has only the module `ldterm` pushed above the `zs` driver, it would produce the following output:

```
ldterm
zs
```

The following command asks if `ldterm` is on the stream:

```
example% strconf -m ldterm
```

and produces the following output while returning an exit status of 0:

```
yes
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`, `streamio(7I)`

DIAGNOSTICS | strchg returns zero on success. It prints an error message and returns non-zero status for various error conditions, including usage error, bad module name, too many modules to push, failure of an ioctl on the stream, or failure to open *filename* from the -f option.

strconf returns zero on success (for the -m or -t option, "success" means the named or topmost module is present). It returns a non-zero status if invoked with the -m or -t option and the module is not present. It prints an error message and returns non-zero status for various error conditions, including usage error or failure of an ioctl on the stream.

NOTES | If the user is neither the owner of the stream nor the super-user, the strchg command will fail. If the user does not have read permissions on the stream and is not the super user, the strconf command will fail.

If modules are pushed in the wrong order, one could end up with a stream that does not function as expected. For ttys, if the line discipline module is not pushed in the correct place, one could have a terminal that does not respond to any commands.

strings(1)

NAME strings – find printable strings in an object or binary file

SYNOPSIS **strings** [-a | -] [-t *format* | -o] [-n *number* | -number] [*file...*]

DESCRIPTION The `strings` utility looks for ASCII strings in a binary file. A string is any sequence of 4 or more printing characters ending with a newline or a null character.

`strings` is useful for identifying random object files and many other things.

OPTIONS The following options are supported:

- a | - Look everywhere in the file for strings. If this flag is omitted, `strings` only looks in the initialized data space of object files.
- n *number* | -*number* Use a *number* as the minimum string length rather than the default, which is 4.
- o Equivalent to -t d option.
- t *format* Write each string preceded by its byte offset from the start of the file. The format is dependent on the single character used as the *format* option-argument:
 - d The offset will be written in decimal.
 - o The offset will be written in octal.
 - x The offset will be written in hexadecimal.

OPERANDS The following operand is supported:

file A path name of a regular file to be used as input. If no *file* operand is specified, the `strings` utility will read from the standard input.

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `strings`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtoo
CSI	Enabled
Interface Stability	Standard

SEE ALSO od(1), attributes(5), environ(5), standards(5)

NOTES The algorithm for identifying strings is extremely primitive.
For backwards compatibility, the options -a and - are interchangeable.

strip(1)

NAME	strip – strip symbol table, debugging and line number information from an object file
SYNOPSIS	<code>/usr/ccs/bin/strip [-blrVx] file...</code>
DESCRIPTION	<p>The <code>strip</code> command removes the symbol table, debugging information, and line number information from ELF object files. Once this stripping process has been done, no symbolic debugging access will be available for that file; therefore, this command is normally run only on production modules that have been debugged and tested.</p> <p>If <code>strip</code> is executed on a common archive file (see <code>ar(3HEAD)</code>) in addition to processing the members, <code>strip</code> will remove the archive symbol table. The archive symbol table must be restored by executing the <code>ar(1)</code> command with the <code>-s</code> option before the archive can be linked by the <code>ld(1)</code> command. <code>strip</code> will produce appropriate warning messages when this situation arises.</p> <p><code>strip</code> is used to reduce the file storage overhead taken by the object file.</p>
OPTIONS	<p>The amount of information stripped from the ELF object file can be controlled by using any of the following options:</p> <ul style="list-style-type: none">-b Same effect as the default behavior. This option is obsolete and will be removed in the next release.-l Strip line number information only; do not strip the symbol table or debugging information.-r Same effect as the default behavior. This option is obsolete and will be removed in the next release.-V Print, on standard error, the version number of <code>strip</code>.-x Do not strip the symbol table; debugging and line number information may be stripped.
OPERANDS	<p>The following operand is supported:</p> <p><i>file</i> A path name referring to an executable file.</p>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>strip</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none">0 Successful completion.>0 An error occurred.
FILES	<code>/tmp/strip*</code> temporary files
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

strip(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool
Interface Stability	Standard

SEE ALSO ar(1), as(1), ld(1), elf(3ELF), tmpnam(3C), a.out(4), ar(3HEAD), attributes(5), environ(5), standards(5)

NOTES The symbol table section will not be removed if it is contained within a segment, or the file is either a relocatable or dynamic shared object.

The line number and debugging sections will not be removed if they are contained within a segment, or their associated relocation section is contained within a segment.

stty(1)

NAME	stty – set the options for a terminal																		
SYNOPSIS	<pre>/usr/bin/stty [-a] [-g] /usr/bin/stty [modes] /usr/xpg4/bin/stty [-a -g] /usr/xpg4/bin/stty [modes]</pre>																		
DESCRIPTION	<p>The <code>stty</code> utility sets certain terminal I/O options for the device that is the current standard input. Without arguments, <code>stty</code> reports the settings of certain options.</p> <p>In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding control character (for example, “^h” is Control-H; in this case, recall that Control-H is the same as the “back-space” key). The sequence “^^” means that an option has a null value.</p> <p>See <code>termio(7I)</code> for detailed information about the modes listed from <code>Control Modes</code> through <code>Local Modes</code>. For detailed information about the modes listed under <code>Hardware Flow Control Modes</code> and <code>Clock Modes</code>, below, see <code>termiox(7I)</code>.</p> <p>Operands described in the <code>Combination Modes</code> section are implemented using options in the earlier sections. Notice that many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options may not be supported by all hardware interfaces.</p>																		
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Writes to standard output all of the option settings for the terminal.-g Reports current settings in a form that can be used as an argument to another <code>stty</code> command. Emits <code>termios</code>-type output if the underlying driver supports it. Otherwise, it emits <code>termio</code>-type output.																		
OPERANDS	The following <i>mode</i> operands are supported:																		
Control Modes	<table><tr><td><code>parenb(-parenb)</code></td><td>Enable (disable) parity generation and detection.</td></tr><tr><td><code>parext(-parext)</code></td><td>Enable (disable) extended parity generation and detection for mark and space parity.</td></tr><tr><td><code>parodd(-parodd)</code></td><td>Select odd (even) parity, or mark (space) parity if <code>parext</code> is enabled.</td></tr><tr><td><code>cs5 cs6 cs7 cs8</code></td><td>Select character size (see <code>termio(7I)</code>).</td></tr><tr><td><code>0</code></td><td>Hang up line immediately.</td></tr><tr><td><code>hupcl (-hupcl)</code></td><td>Hang up (do not hang up) connection on last close.</td></tr><tr><td><code>hup (-hup)</code></td><td>Same as <code>hupcl(-hupcl)</code>.</td></tr><tr><td><code>cstopb (-cstopb)</code></td><td>Use two (one) stop bits per character.</td></tr><tr><td><code>cread (-cread)</code></td><td>Enable (disable) the receiver.</td></tr></table>	<code>parenb(-parenb)</code>	Enable (disable) parity generation and detection.	<code>parext(-parext)</code>	Enable (disable) extended parity generation and detection for mark and space parity.	<code>parodd(-parodd)</code>	Select odd (even) parity, or mark (space) parity if <code>parext</code> is enabled.	<code>cs5 cs6 cs7 cs8</code>	Select character size (see <code>termio(7I)</code>).	<code>0</code>	Hang up line immediately.	<code>hupcl (-hupcl)</code>	Hang up (do not hang up) connection on last close.	<code>hup (-hup)</code>	Same as <code>hupcl(-hupcl)</code> .	<code>cstopb (-cstopb)</code>	Use two (one) stop bits per character.	<code>cread (-cread)</code>	Enable (disable) the receiver.
<code>parenb(-parenb)</code>	Enable (disable) parity generation and detection.																		
<code>parext(-parext)</code>	Enable (disable) extended parity generation and detection for mark and space parity.																		
<code>parodd(-parodd)</code>	Select odd (even) parity, or mark (space) parity if <code>parext</code> is enabled.																		
<code>cs5 cs6 cs7 cs8</code>	Select character size (see <code>termio(7I)</code>).																		
<code>0</code>	Hang up line immediately.																		
<code>hupcl (-hupcl)</code>	Hang up (do not hang up) connection on last close.																		
<code>hup (-hup)</code>	Same as <code>hupcl(-hupcl)</code> .																		
<code>cstopb (-cstopb)</code>	Use two (one) stop bits per character.																		
<code>cread (-cread)</code>	Enable (disable) the receiver.																		

	<code>crtscts (-crtscts)</code>	Enable output hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.
	<code>crtsxoff (-crtsxoff)</code>	Enable input hardware flow control. Raise the RTS (Request to Send) modem control line to receive data. Suspends input when RTS is low.
	<code>clocal (-clocal)</code>	Assume a line without (with) modem control.
	<code>defeucw</code>	Set the widths of multibyte characters to the values defined in the current locale specified by <code>LC_CTYPE</code> . Internally, width is expressed in terms of bytes per character, and screen or display columns per character.
	110 300 600 1200 1800 2400 4800 9600 19200 38400 357600 76800 115200 153600 230400 307200 460800	Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)
	<code>ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400 57600 76800 115200 153600 230400 307200 460800</code>	Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to 0, the input baud rate will be specified by the value of the output baud rate.
	<code>ospeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400 57600 76800 115200 153600 230400 307200 460800</code>	Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the output baud rate is set to 0, the line will be hung up immediately.
Input Modes	<code>ignbrk (-ignbrk)</code>	Ignore (do not ignore) break on input.
	<code>brkint (-brkint)</code>	Signal (do not signal) INTR on break.
	<code>ignpar (-ignpar)</code>	Ignore (do not ignore) parity errors.
	<code>parmrk (-parmrk)</code>	Mark (do not mark) parity errors (see <code>termio(7I)</code>).
	<code>inpck (-inpck)</code>	Enable (disable) input parity checking.
	<code>istrip (-istrip)</code>	Strip (do not strip) input characters to seven bits.

stty(1)

	<code>inlcr (-inlcr)</code>	Map (do not map) NL to CR on input.
	<code>igncr (-igncr)</code>	Ignore (do not ignore) CR on input.
	<code>icrnl (-icrnl)</code>	Map (do not map) CR to NL on input.
	<code>iuclc (-iuclc)</code>	Map (do not map) upper-case alphabets to lower case on input.
	<code>ixon (-ixon)</code>	Enable (disable) START/STOP output control. Output is stopped by sending STOP control character and started by sending the START control character.
	<code>ixany (-ixany)</code>	Allow any character (only DC1) to restart output.
	<code>ixoff (-ixoff)</code>	Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.
	<code>imaxbel (-imaxbel)</code>	Echo (do not echo) BEL when the input line is too long.
Output Modes	<code>opost (-opost)</code>	Post-process output (do not post-process output; ignore all other output modes).
	<code>olcuc (-olcuc)</code>	Map (do not map) lower-case alphabets to upper case on output.
	<code>onlcr (-onlcr)</code>	Map (do not map) NL to CR-NL on output.
	<code>ocrnl (-ocrnl)</code>	Map (do not map) CR to NL on output.
	<code>onocr (-onocr)</code>	Do not (do) output CRs at column zero.
	<code>onlret (-onlret)</code>	On the terminal NL performs (does not perform) the CR function.
	<code>ofill (-ofill)</code>	Use fill characters (use timing) for delays.
	<code>ofdel (-ofdel)</code>	Fill characters are DELs (NULs).
	<code>cr0 cr1 cr2 cr3</code>	Select style of delay for carriage returns (see <code>termio(7I)</code>).
	<code>nl0 nl1</code>	Select style of delay for line-feeds (see <code>termio(7I)</code>).
	<code>tab0 tab1 tab2 tab3</code>	Select style of delay for horizontal tabs (see <code>termio(7I)</code>).
	<code>bs0 bs1</code>	Select style of delay for backspaces (see <code>termio(7I)</code>).
	<code>ff0 ff1</code>	Select style of delay for form-feeds (see <code>termio(7I)</code>).
	<code>vt0 vt1</code>	Select style of delay for vertical tabs (see <code>termio(7I)</code>).
Local Modes	<code>isig(-isig)</code>	Enable (disable) the checking of characters against the special control characters INTR, QUIT, SWTCH, and SUSP.

icanon (-icanon)	Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.
xcase (-xcase)	Canonical (unprocessed) upper/lower-case presentation.
echo (-echo)	Echo back (do not echo back) every character typed.
echoe (-echoe)	Echo (do not echo) ERASE character as a backspace-space-backspace string. Note: This mode will erase the ERASEed character on many CRT terminals; however, it does not keep track of column position and, as a result, it may be confusing for escaped characters, tabs, and backspaces.
echok(-echok)	Echo (do not echo) NL after KILL character.
lfkc (-lfkc)	The same as echok(-echok); obsolete.
echonl (-echonl)	Echo (do not echo) NL.
noflsh (-noflsh)	Disable (enable) flush after INTR, QUIT, or SUSP.
stwrap (-stwrap)	Disable (enable) truncation of lines longer than 79 characters on a synchronous line.
tostop (-tostop)	Send (do not send) SIGTTOU when background processes write to the terminal.
echoctl (-echoctl)	Echo (do not echo) control characters as <i>^char</i> , delete as <i>^?</i> .
echoprt (-echoprt)	Echo (do not echo) erase character as character is "erased".
echoke (-echoke)	BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.
flusho (-flusho)	Output is (is not) being flushed.
pendin (-pendin)	Retype (do not retype) pending input at next read or input character.
iexten (-iexten)	Enable (disable) special control characters not currently controlled by icanon, isig, ixon, or ixoff: VEOLZ, VSWTCH, VREPRINT, VDISCARD, VDSUSP, VWERASE, and VLNEXT.
stflush (-stflush)	Enable (disable) flush on a synchronous line after every write(2).
stappl (-stappl)	Use application mode (use line mode) on a synchronous line.
rtsxoff (-rtsxoff)	Enable (disable) RTS hardware flow control on input.

stty(1)

	<code>ctsxon (-ctsxon)</code>	Enable (disable) CTS hardware flow control on output.
	<code>dtrxoff (-dtrxoff)</code>	Enable (disable) DTR hardware flow control on input.
	<code>cdxon (-cdxon)</code>	Enable (disable) CD hardware flow control on output.
	<code>isxoff (-isxoff)</code>	Enable (disable) isochronous hardware flow control on input.
Clock Modes	<code>xcibrg</code>	Get transmit clock from internal baud rate generator.
	<code>xctset</code>	Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	<code>xcrset</code>	Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	<code>rcibrg</code>	Get receive clock from internal baud rate generator.
	<code>rctset</code>	Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	<code>rcrset</code>	Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	<code>tsetcoff</code>	Transmitter signal element timing clock not provided.
	<code>tsetcrbrg</code>	Output receive baud rate generator on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	<code>tsetctbrg</code>	Output transmit baud rate generator on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	<code>tsetctset</code>	Output transmitter signal element timing (DCE source) on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	<code>tsetcrset</code>	Output receiver signal element timing (DCE source) on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	<code>rsetcoff</code>	Receiver signal element timing clock not provided.
	<code>rsetcrbrg</code>	Output receive baud rate generator on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.
	<code>rsetctbrg</code>	Output transmit baud rate generator on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.
	<code>rsetctset</code>	Output transmitter signal element timing (DCE source) on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.

Control Assignments

`rsetcrset` Output receiver signal element timing (DCE source) on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.

control-character c

Set *control-character* to *c*, where:

control-character

is `ctab`, `discard`, `dsusp`, `eof`, `eol`, `eol2`, `erase`, `intr`, `kill`, `lnext`, `quit`, `reprint`, `start`, `stop`, `susp`, `swtch`, or `werase` (`ctab` is used with `-stappl`, see `termio(7I)`).

c

If *c* is a single character, the control character will be set to that character.

In the POSIX locale, if *c* is preceded by a caret (^) indicating an escape from the shell and is one of those listed in the `^c` column of the following table, then its value used (in the Value column) is the corresponding control character (for example, `^^d` is a CTRL-D). `^^?` is interpreted as DEL and `^^-` is interpreted as undefined.

<code>^c</code>	Value	<code>^c</code>	Value	<code>^c</code>	Value
a, A	<SOH>	l, L	<FF>	w, W	<ETB>
b, B	<STX>	m, M	<CR>	x, X	<CAN>
c, C	<ETX>	n, N	<SO>	y, Y	
d, D	<EOT>	o, O	<SI>	z, Z	<SUB>
e, E	<ENQ>	p, P	<DLE>	[<ESC>
f, F	<ACK>	q, Q	<DC1>	\	<FS>
g, G	<BEL>	r, R	<DC2>]	<GS>
h, H	<BS>	s, S	<DC3>	^	<RS>
i, I	<HT>	t, T	<DC4>	_	<US>
j, J	<LF>	u, U	<NAK>	?	
k, K	<VT>	v, V	<SYN>		

min number
time number

Set the value of `min` or `time` to *number*. `MIN` and `TIME` are used in Non-Canonical mode input processing (`-icanon`).

stty(1)

	line <i>i</i>	Set line discipline to <i>i</i> ($0 < i < 127$).	
Combination Modes	<i>saved settings</i>	Set the current terminal characteristics to the saved settings produced by the <code>-g</code> option.	
	evenp or parity	Enable parenb and cs7, or disable parodd.	
	oddp	Enable parenb, cs7, and parodd.	
	spacep	Enable parenb, cs7, and parext.	
	markp	Enable parenb, cs7, parodd, and parext.	
	-parity, or -evenp	Disable parenb, and set cs8.	
	-oddp	Disable parenb and parodd, and set cs8.	
	-spacep	Disable parenb and parext, and set cs8.	
	-markp	Disable parenb, parodd, and parext, and set cs8.	
	raw (-raw or cooked)	Enable (disable) raw input and output. Raw mode is equivalent to setting: <pre>stty cs8 -icanon min 1 time 0 -isig -xcase \ -inpck -opost</pre>	
	/usr/bin/stty	nl (-nl)	Unset (set) icrnl, onlcr. In addition -nl unsets inlcr, igncr, ocrnl, and onlret.
	/usr/xpg4/bin/stty	nl (-nl)	Set (unset) icrnl. In addition, -nl unsets inlcr, igncr, ocrnl, and onlret; -nl sets onlcr, and nl unsets onlcr.
	lcase (-lcase)	Set (unset) xcase, iuclc, and olcuc.	
	LCASE (-LCASE)	Same as lcase (-lcase).	
	tabs (-tabs or tab3)	Preserve (expand to spaces) tabs when printing.	
	ek	Reset ERASE and KILL characters back to normal # and @.	
	sane	Resets all modes to some reasonable values.	
	term	Set all modes suitable for the terminal type <i>term</i> , where <i>term</i> is one of tty33, tty37, vt05, tn300, ti700, or tek.	
	async	Set normal asynchronous communications where clock settings are xcibrg, rcibrg, tsetcoff and rsetcoff.	
Window Size	rows <i>n</i>	Set window size to <i>n</i> rows.	
	columns <i>n</i>	Set window size to <i>n</i> columns.	

`cols n` Set window size to *n* columns. Note that `cols` is a shorthand alias for columns.

`ypixels n` Set vertical window size to *n* pixels.

`xpixels n` Set horizontal window size to *n* pixels.

USAGE The `-g` flag is designed to facilitate the saving and restoring of terminal state from the shell level. For example, a program may:

```
saveterm="$(stty -g)"       # save terminal state
stty (new settings)       # set new state
. . .                      # . . .
stty $saveterm            # restore terminal state
```

Since the `-a` format is so loosely specified, scripts that save and restore terminal settings should use the `-g` option.

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `stty`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/stty`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`/usr/xpg4/bin/stty`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
Interface Stability	Standard

stty(1B)

NAME	stty – set the options for a terminal
SYNOPSIS	<code>/usr/ucb/stty [-a] [-g] [-h] [modes]</code>
DESCRIPTION	<code>stty</code> sets certain terminal I/O options for the device that is the current standard output; without arguments, it reports the settings of certain options.
OPTIONS	<p>In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding CTRL character (for example, “^h” is CTRL-H; in this case, recall that CTRL-H is the same as the “back-space” key.) The sequence “^'” means that an option has a null value.</p> <p>-a Report all of the option settings.</p> <p>-g Report current settings in a form that can be used as an argument to another <code>stty</code> command.</p> <p>-h Report all the option settings with the control characters in an easy to read column format.</p> <p>Options in the last group are implemented using options in the previous groups. Note: Many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options may not be supported by all hardware interfaces. The options are selected from the following:</p>
Special Requests	<p>all Reports the same option settings as <code>stty</code> without arguments, but with the control characters in column format.</p> <p>everything Everything <code>stty</code> knows about is printed. Same as -h option.</p> <p>speed The terminal speed alone is reported on the standard output.</p> <p>size The terminal (window) sizes are printed on the standard output, first rows and then columns. This option is only appropriate if currently running a window system.</p> <p> size and speed always report on the settings of <code>/dev/tty</code>, and always report the settings to the standard output.</p>
Control Modes	<p>parenb (-parenb) Enable (disable) parity generation and detection.</p> <p>parext (-parext) Enable (disable) extended parity generation and detection for mark and space parity.</p> <p>parodd (-parodd) Select odd (even) parity, or mark (space) parity if <code>parext</code> is enabled.</p> <p>cs5 cs6 cs7 cs8 Select character size (see <code>termio(7I)</code>).</p> <p>0 Hang up line immediately.</p>

110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb

Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)

ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 exta 38400
extb

Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to zero, the input baud rate will be specified by the value of the output baud rate.

ospeed 0 110 300 600 1200 1800 2400 4800 9600 19200 exta 38400
extb

Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the baud rate is set to zero, the line will be hung up immediately.

hupcl (-hupcl)

Hang up (do not hang up) connection on last close.

hup (-hup)

Same as hupcl (-hupcl).

cstopb (-cstopb)

Use two (one) stop bits per character.

cread (-cread)

Enable (disable) the receiver.

clocal (-clocal)

Assume a line without (with) modem control.

crtsets (-crtsets)

Enable hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.

loblk (-loblk)

Block (do not block) output from a non-current layer.

Input Modes

ignbrk (-ignbrk) Ignore (do not ignore) break on input.

brkint (-brkint) Signal (do not signal) INTR on break.

ignpar (-ignpar) Ignore (do not ignore) parity errors.

parmrk (-parmrk) Mark (do not mark) parity errors (see `termio(7I)`).

inpck (-inpck) Enable (disable) input parity checking.

istrip (-istrip) Strip (do not strip) input characters to seven bits.

inlcr (-inlcr) Map (do not map) NL to CR on input.

igncr (-igncr) Ignore (do not ignore) CR on input.

icrnl (-icrnl) Map (do not map) CR to NL on input.

stty(1B)

	iuclc (-iuclc)	Map (do not map) upper-case alphabetic to lower case on input.
	ixon (-ixon)	Enable (disable) START/STOP output control. Output is stopped by sending an STOP and started by sending an START.
	ixany (-ixany)	Allow any character (only START) to restart output.
	decctlq (-decctlq)	Same as -ixany.
	ixoff (-ixoff)	Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.
	tandem (-tandem)	Same as ixoff.
	imaxbel (-imaxbel)	Echo (do not echo) BEL when the input line is too long.
	iexten (-iexten)	Enable (disable) extended (implementation-defined) functions for input data.
Output Modes	opost (-opost)	Post-process output (do not post-process output; ignore all other output modes).
	olcuc (-olcuc)	Map (do not map) lower-case alphabetic to upper case on output.
	onlcr (-onlcr)	Map (do not map) NL to CR-NL on output.
	ocrnl (-ocrnl)	Map (do not map) CR to NL on output.
	onocr (-onocr)	Do not (do) output CRs at column zero.
	onlret (-onlret)	On the terminal NL performs (does not perform) the CR function.
	ofill (-ofill)	Use fill characters (use timing) for delays.
	ofdel (-ofdel)	Fill characters are DELs (NULs).
	cr0 cr1 cr2 cr3	Select style of delay for carriage returns (see <code>termio(7I)</code>).
	nl0 nl1	Select style of delay for line-feeds (see <code>termio(7I)</code>).
	tab0 tab1 tab2 tab3	Select style of delay for horizontal tabs (see <code>termio(7I)</code>).
	bs0 bs1	Select style of delay for backspaces (see <code>termio(7I)</code>).
	ff0 ff1	Select style of delay for form-feeds (see <code>termio(7I)</code>).
	vt0 vt1	Select style of delay for vertical tabs (see <code>termio(7I)</code>).
Local Modes	isig (-isig)	Enable (disable) the checking of characters against the special control characters INTR, QUIT, and SWTCH.

icanon (-icanon)	Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.
cbreak (-cbreak)	Equivalent to -icanon min 1 time 0.
xcase (-xcase)	Canonical (unprocessed) upper/lower-case presentation.
echo (-echo)	Echo back (do not echo back) every character typed.
echoe (-echoe)	Echo (do not echo) ERASE character as a backspace-space-backspace string. Note: This mode will erase the ERASEed character on many CRT terminals; however, it does <i>not</i> keep track of column position and, as a result, may be confusing on escaped characters, tabs, and backspaces.
crterase (-crterase)	Same as echoe.
echok (-echok)	Echo (do not echo) NL after KILL character.
lfkc (-lfkc)	The same as echok (-echok); obsolete.
echonl (-echonl)	Echo (do not echo) NL.
noflsh (-noflsh)	Disable (enable) flush after INTR, QUIT, or SWITCH.
stwrap (-stwrap)	Disable (enable) truncation of lines longer than 79 characters on a synchronous line. (Does not apply to the 3B2.)
tostop (-tostop)	Send (do not send) SIGTTOU for background processes.
echoctl (-echoctl)	Echo (do not echo) control characters as <i>^char</i> , delete as <i>^?</i>
ctlecho (-ctlecho)	Same as echoctl.
echoprt (-echoprt)	Echo (do not echo) erase character as character is "erased".
prterase (-prterase)	Same as echoprt.
echoke (-echoke)	BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.
crtkill (-crtkill)	Same as echoke.
flusho (-flusho)	Output is (is not) being flushed.
pendin (-pendin)	Retype (do not retype) pending input at next read or input character.
stflush (-stflush)	Enable (disable) flush on a synchronous line after every write(2). (Does not apply to the 3B2.)

stty(1B)

	stappl (-stappl)	Use application mode (use line mode) on a synchronous line. (Does not apply to the 3B2.)
Hardware Flow Control Modes	rtsxoff (-rtsxoff)	Enable (disable) RTS hardware flow control on input.
	ctsxon (-ctsxon)	Enable (disable) CTS hardware flow control on output.
	dterxoff (-dterxoff)	Enable (disable) DTER hardware flow control on input.
	rlsdxon (-rlsdxon)	Enable (disable) RLSD hardware flow control on output.
	isxoff (-isxoff)	Enable (disable) isochronous hardware flow control on input.
Clock Modes	xcibrg	Get transmit clock from internal baud rate generator.
	xctset	Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	xcrset	Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	rcibrg	Get receive clock from internal baud rate generator.
	rctset	Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	rcrset	Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	tsetcoff	Transmitter signal element timing clock not provided.
	tsetcrc	Output receive clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.
	tsetcxc	Output transmit clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.
	rsetcoff	Receiver signal element timing clock not provided.
	rsetcrc	Output receive clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.
	rsetcxc	Output transmit clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.

Control Assignments	<i>control-character c</i>	Set <i>control-character</i> to <i>c</i> , where <i>control-character</i> is <i>intr</i> , <i>quit</i> , <i>erase</i> , <i>kill</i> , <i>eof</i> , <i>eol</i> , <i>eol2</i> , <i>swtch</i> , <i>start</i> , <i>stop</i> , <i>susp</i> , <i>dsusp</i> , <i>rprnt</i> , <i>flush</i> , <i>werase</i> , <i>lnext</i> , <i>min</i> , <i>ctab</i> , <i>time</i> , or <i>brk</i> (<i>ctab</i> is used with <i>-stappl</i> ; <i>min</i> and <i>time</i> are used with <i>-icanon</i> ; see <i>termio(7I)</i>). If <i>c</i> is preceded by an (escaped from the shell) caret (^), then the value used is the corresponding CTRL character (for example, “^d” is a CTRL-d); “^?” is interpreted as DEL and “^-” is interpreted as undefined.
Combination Modes	line <i>i</i>	Set line discipline to <i>i</i> ($0 < i < 127$).
	evenp or parity	Enable parenb and cs7.
	-evenp, or -parity	Disable parenb, and set cs8.
	even (-even)	Same as evenp (-evenp).
	oddp	Enable parenb, cs7, and parodd.
	-oddp	Disable parenb and parodd, and set cs8.
	odd (-odd)	Same as oddp (-oddp).
	spacep	Enable parenb, cs7, and parext.
	-spacep	Disable parenb and parext, and set cs8.
	markp	Enable parenb, cs7, parodd, and parext.
	-markp	Disable parenb, parodd, and parext, and set cs8.
	raw (-raw or cooked)	Enable (disable) raw input and output (no ERASE, KILL, INTR, QUIT, SWTCH, EOT, or output post processing).
	nl (-nl)	Unset (set) <i>icrnl</i> , <i>onlcr</i> . In addition <i>-nl</i> unsets <i>inlcr</i> , <i>igncr</i> , <i>ocrnl</i> , and <i>onlret</i> .
	lcase (-lcase)	Set (unset) <i>xcase</i> , <i>iuclc</i> , and <i>olcuc</i> .
	LCASE (-LCASE)	Same as <i>lcase</i> (- <i>lcase</i>).
	tabs (-tabs or tab3)	Preserve (expand to spaces) tabs when printing.
	ek	Reset ERASE and KILL characters back to normal # and @.
	sane	Resets all modes to some reasonable values.
	term	Set all modes suitable for the terminal type <i>term</i> , where <i>term</i> is one of <i>tty33</i> , <i>tty37</i> , <i>vt05</i> , <i>tn300</i> , <i>ti700</i> , or <i>tek</i> .

stty(1B)

	<code>async</code>	Set normal asynchronous communications where clock settings are <code>xcibrg</code> , <code>rcibrg</code> , <code>tsetcoff</code> and <code>rsetcoff</code> .
	<code>litout (-litout)</code>	Disable (enable) <code>parenb</code> , <code>istrip</code> , and <code>opost</code> , and set <code>cs8</code> (<code>cs7</code>).
	<code>pass8 (-pass8)</code>	Disable (enable) <code>parenb</code> and <code>istrip</code> , and set <code>cs8</code> (<code>cs7</code>).
	<code>crt</code>	Set options for a CRT (<code>echoe</code> , <code>echoctl</code> , and, if \geq 1200 baud, <code>echoke</code> .)
	<code>dec</code>	Set all modes suitable for Digital Equipment Corp. operating systems users ERASE, KILL, and INTR characters to <code>^?</code> , <code>^U</code> , and <code>^C</code> , <code>decctlq</code> , and <code>crt</code> .)
Window Size	<code>rowsn</code>	Set window size to <i>n rows</i> .
	<code>columnsn</code>	Set window size to <i>n columns</i> .
	<code>colsn</code>	An alias for <code>columns n</code> .
	<code>ypixelsn</code>	Set vertical window size to <i>n pixels</i> .
	<code>xpixelsn</code>	Set horizontal window size to <i>n pixels</i> .

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO `tabs(1)`, `ioctl(2)`, `attributes(5)`, `termio(7I)`, `termiox(7I)`

NAME	sum – print checksum and block count for a file						
SYNOPSIS	sum [-r] [<i>file...</i>]						
DESCRIPTION	The <code>sum</code> utility calculates and prints a 16-bit checksum for the named file and the number of 512-byte blocks in the file. It is typically used to look for bad spots, or to validate a file communicated over some transmission line.						
OPTIONS	The following options are supported: -r Use an alternate (machine-dependent) algorithm in computing the checksum.						
OPERANDS	The following operands are supported: <i>file</i> A path name of a file. If no files are named, the standard input is used.						
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>sum</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>sum</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS	The following exit values are returned. 0 Successful completion. >0 An error occurred.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWesu</td> </tr> <tr> <td>CSI</td> <td>enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu	CSI	enabled
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWesu						
CSI	enabled						
SEE ALSO	<code>cksum(1)</code> , <code>sum(1B)</code> , <code>wc(1)</code> , <code>attributes(5)</code> , <code>environ(5)</code> , <code>largefile(5)</code>						
DIAGNOSTICS	“Read error” is indistinguishable from end of file on most devices; check the block count.						
NOTES	Portable applications should use <code>cksum(1)</code> . <code>sum</code> and <code>usr/ucb/sum</code> (see <code>sum(1B)</code>) return different checksums.						

sum(1B)

NAME | sum – calculate a checksum for a file

SYNOPSIS | */usr/ucb/sum file...*

DESCRIPTION | sum calculates and displays a 16-bit checksum for the named file and displays the size of the file in kilobytes. It is typically used to look for bad spots, or to validate a file communicated over some transmission line. The checksum is calculated by an algorithm which may yield different results on machines with 16-bit ints and machines with 32-bit ints, so it cannot always be used to validate that a file has been transferred between machines with different-sized ints.

USAGE | See `largefile(5)` for the description of the behavior of `sum` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO | `sum(1)`, `wc(1)`, `attributes(5)`, `largefile(5)`

DIAGNOSTICS | Read error is indistinguishable from EOF on most devices; check the block count.

NOTES | `sum` and `/usr/bin/sum` (see `sum(1)`) return different checksums.

This utility is obsolete.

suspend(1)

NAME suspend – shell built-in function to halt the current shell

sh **suspend**

csh **suspend**

ksh **suspend**

sh Stops the execution of the current shell (but not if it is the login shell).

csh Stop the shell in its tracks, much as if it had been sent a stop signal with ^Z. This is most often used to stop shells started by su.

ksh Stops the execution of the current shell (but not if it is the login shell).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `csh(1)`, `kill(1)`, `ksh(1)`, `sh(1)`, `su(1M)`, `attributes(5)`

symorder(1)

NAME symorder – rearrange a list of symbols

SYNOPSIS **symorder** [-s] *objectfile symbolfile*

DESCRIPTION *symorder* was used in SunOS 4.x specifically to cut down on the overhead of getting symbols from *vmunix*. This is no longer applicable as kernel symbol entries are dynamically obtained through */dev/ksyms*.

This script is provided as a convenience for software developers who need to maintain scripts that are portable across a variety of operating systems.

EXIT STATUS *symorder* has exit status 0.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

SEE ALSO *nlist(3ELF)*, *attributes(5)*, *ksyms(7D)*.

NAME	sysV-make – maintain, update, and regenerate groups of programs
SYNOPSIS	<code>/usr/lib/svr4.make [-f <i>makefile</i>] [-eiknpqrst] [<i>names</i>]</code>
DESCRIPTION	<p>This is the “vanilla” System V version of make. If the environment variable <code>USE_SVR4_MAKE</code> is set, then the command <code>make</code> will invoke this version of make. (See also the <code>ENVIRONMENT</code> section.)</p> <p><code>make</code> allows the programmer to maintain, update, and regenerate groups of computer programs. <code>make</code> executes commands in <i>makefile</i> to update one or more target <i>names</i> (<i>names</i> are typically programs). If the <code>-f</code> option is not present, then <code>makefile</code>, <code>Makefile</code>, and the Source Code Control System (SCCS) files <code>s.makefile</code> and <code>s.Makefile</code> are tried in order. If <i>makefile</i> is <code>'-'</code> the standard input is taken. More than one <code>-f <i>makefile</i></code> argument pair may appear.</p> <p><code>make</code> updates a target only if its dependents are newer than the target. All prerequisite files of a target are added recursively to the list of targets. Missing files are deemed to be outdated.</p> <p>The following list of four directives can be included in <i>makefile</i> to extend the options provided by <code>make</code>. They are used in <i>makefile</i> as if they were targets:</p> <p><code>.DEFAULT :</code> If a file must be made but there are no explicit commands or relevant built-in rules, the commands associated with the name <code>.DEFAULT</code> are used if it exists.</p> <p><code>.IGNORE :</code> Same effect as the <code>-i</code> option.</p> <p><code>.PRECIOUS :</code> Dependents of the <code>.PRECIOUS</code> entry will not be removed when quit or interrupt are hit.</p> <p><code>.SILENT :</code> Same effect as the <code>-s</code> option.</p>
Options	<p>The options for <code>make</code> are listed below:</p> <p><code>-e</code> Environment variables override assignments within makefiles.</p> <p><code>-f <i>makefile</i></code> Description filename (<i>makefile</i> is assumed to be the name of a description file).</p> <p><code>-i</code> Ignore error codes returned by invoked commands.</p> <p><code>-k</code> Abandon work on the current entry if it fails, but continue on other branches that do not depend on that entry.</p> <p><code>-n</code> No execute mode. Print commands, but do not execute them. Even command lines beginning with an <code>'@'</code> are printed.</p> <p><code>-p</code> Print out the complete set of macro definitions and target descriptions.</p> <p><code>-q</code> Question. <code>make</code> returns a zero or non-zero status code depending on whether or not the target file has been updated.</p> <p><code>-r</code> Do not use the built-in rules.</p>

Creating the makefile

- s Silent mode. Do not print command lines before executing.
- t Touch the target files (causing them to be updated) rather than issue the usual commands.

The makefile invoked with the `-f` option is a carefully structured file of explicit instructions for updating and regenerating programs, and contains a sequence of entries that specify dependencies. The first line of an entry is a blank-separated, non-null list of targets, then a `:`, then a (possibly null) list of prerequisite files or dependencies. Text following a `:` and all following lines that begin with a tab are shell commands to be executed to update the target. The first non-empty line that does not begin with a tab or `#` begins a new dependency or macro definition. Shell commands may be continued across lines with a backslash-new-line (`\-NEWLINE`) sequence. Everything printed by make (except the initial TAB) is passed directly to the shell as is. Thus,

```
echo a\  
b
```

will produce

```
ab
```

exactly the same as the shell would.

Number-sign (`#`) and `NEWLINE` surround comments including contained `\-NEWLINE` sequences.

The following makefile says that `pgm` depends on two files `a.o` and `b.o`, and that they in turn depend on their corresponding source files (`a.c` and `b.c`) and a common file `incl.h`:

```
pgm: a.o b.o  
    cc a.o b.o -o pgm  
a.o: incl.h a.c  
    cc -c a.c  
b.o: incl.h b.c  
    cc -c b.c
```

Command lines are executed one at a time, each by its own shell. The `SHELL` environment variable can be used to specify which shell make should use to execute commands. The default is `/usr/bin/sh`. The first one or two characters in a command can be the following: `@`, `-`, `@-`, or `-@`. If `@` is present, printing of the command is suppressed. If `-` is present, make ignores an error. A line is printed when it is executed unless the `-s` option is present, or the entry `.SILENT:` is included in *makefile*, or unless the initial character sequence contains a `@`. The `-n` option specifies

printing without execution; however, if the command line has the string `$(MAKE)` in it, the line is always executed (see the discussion of the `MAKEFLAGS` macro in the `make Environment` sub-section below). The `-t` (`touch`) option updates the modified date of a file without executing any commands.

Commands returning non-zero status normally terminate `make`. If the `-i` option is present, if the entry `.IGNORE:` is included in *makefile*, or if the initial character sequence of the command contains `'-`', the error is ignored. If the `-k` option is present, work is abandoned on the current entry, but continues on other branches that do not depend on that entry.

`Interrupt` and `quit` cause the target to be deleted unless the target is a dependent of the directive `.PRECIOUS`.

make Environment

The environment is read by `make`. All variables are assumed to be macro definitions and are processed as such. The environment variables are processed before any *makefile* and after the internal rules; thus, macro assignments in a *makefile* override environment variables. The `-e` option causes the environment to override the macro assignments in a *makefile*. Suffixes and their associated rules in the *makefile* will override any identical suffixes in the built-in rules.

The `MAKEFLAGS` environment variable is processed by `make` as containing any legal input option (except `-f` and `-p`) defined for the command line. Further, upon invocation, `make` “invents” the variable if it is not in the environment, puts the current options into it, and passes it on to invocations of commands. Thus, `MAKEFLAGS` always contains the current input options. This feature proves very useful for “super-makes”. In fact, as noted above, when the `-n` option is used, the command `$(MAKE)` is executed anyway; hence, one can perform a `make -n` recursively on a whole software system to see what would have been executed. This result is possible because the `-n` is put in `MAKEFLAGS` and passed to further invocations of `$(MAKE)`. This usage is one way of debugging all of the *makefiles* for a software project without actually doing anything.

Include Files

If the string *include* appears as the first seven letters of a line in a *makefile*, and is followed by a blank or a tab, the rest of the line is assumed to be a filename and will be read by the current invocation, after substituting for any macros.

Macros

Entries of the form *string1* = *string2* are macro definitions. *string2* is defined as all characters up to a comment character or an unescaped `NEWLINE`. Subsequent appearances of `$(string1[:subst1=[subst2]])` are replaced by *string2*. The parentheses are optional if a single-character macro name is used and there is no substitute sequence. The optional `:subst1=subst2` is a substitute sequence. If it is specified, all non-overlapping occurrences of *subst1* in the named macro are replaced by *subst2*. Strings (for the purposes of this type of substitution) are delimited by `BLANKs`, `TABs`, `NEWLINE` characters, and beginnings of lines. An example of the use of the substitute sequence is shown in the `Libraries` sub-section below.

sysV-make(1)

Internal Macros

There are five internally maintained macros that are useful for writing rules for building targets.

\$* The macro `$*` stands for the filename part of the current dependent with the suffix deleted. It is evaluated only for inference rules.

\$@ The `$@` macro stands for the full target name of the current target. It is evaluated only for explicitly named dependencies.

\$< The `$<` macro is only evaluated for inference rules or the `.DEFAULT` rule. It is the module that is outdated with respect to the target (the “manufactured” dependent file name). Thus, in the `.c.o` rule, the `$<` macro would evaluate to the `.c` file. An example for making optimized `.o` files from `.c` files is:

```
.c.o:
    cc -c -O $*.c
```

or:

```
.c.o:
    cc -c -O $<
```

\$? The `$?` macro is evaluated when explicit rules from the makefile are evaluated. It is the list of prerequisites that are outdated with respect to the target, and essentially those modules that must be rebuilt.

\$% The `$%` macro is only evaluated when the target is an archive library member of the form `lib(file.o)`. In this case, `$@` evaluates to `lib` and `$%` evaluates to the library member, `file.o`.

Four of the five macros can have alternative forms. When an upper case `D` or `F` is appended to any of the four macros, the meaning is changed to “directory part” for `D` and “file part” for `F`. Thus, `$(@D)` refers to the directory part of the string `$@`. If there is no directory part, `./` is generated. The only macro excluded from this alternative form is `$?`.

Suffixes

Certain names (for instance, those ending with `.o`) have inferable prerequisites such as `.c`, `.s`, etc. If no update commands for such a file appear in *makefile*, and if an inferable prerequisite exists, that prerequisite is compiled to make the target. In this case, *make* has inference rules that allow building files from other files by examining the suffixes and determining an appropriate inference rule to use. The current default inference rules are:

<code>.c</code>	<code>.c~</code>	<code>.f</code>	<code>.f~</code>	<code>.s</code>	<code>.s~</code>	<code>.sh</code>	<code>.sh~</code>	<code>.C</code>	<code>.C~</code>
<code>.c.a</code>	<code>.c.o</code>	<code>.c~.a</code>	<code>.c~.c</code>	<code>.c~.o</code>	<code>.f.a</code>	<code>.f.o</code>	<code>.f~.a</code>	<code>.f~.f</code>	<code>.f~.o</code>
<code>.h~.h</code>	<code>.l.c</code>	<code>.l.o</code>	<code>.l~.c</code>	<code>.l~.l</code>	<code>.l~.o</code>	<code>.s.a</code>	<code>.s.o</code>	<code>.s~.a</code>	<code>.s~.o</code>

.s~s	.sh~sh	.y.c	.y.o	.y~c	.y~o	.y~y	.C.a	.C.o	.C~a
.C~C	.C~o	.L.C	.L.o	.L~C	.L~L	.L~o	.Y.C	.Y.o	.Y~C
.Y~o	.Y~Y								

The internal rules for make are contained in the source file `make.rules` for the make program. These rules can be locally modified. To print out the rules compiled into the make on any machine in a form suitable for recompilation, the following command is used:

```
make -pf - 2>/dev/null </dev/null
```

A tilde in the above rules refers to an SCCS file (see `sccsfile(4)`). Thus, the rule `.c~.o` would transform an SCCS C source file into an object file (`.o`). Because the `s.` of the SCCS files is a prefix, it is incompatible with the make suffix point of view. Hence, the tilde is a way of changing any file reference into an SCCS file reference.

A rule with only one suffix (for example, `.c:`) is the definition of how to build `x` from `x.c`. In effect, the other suffix is null. This feature is useful for building targets from only one source file, for example, shell procedures and simple C programs.

Additional suffixes are given as the dependency list for `.SUFFIXES`. Order is significant: the first possible name for which both a file and a rule exist is inferred as a prerequisite. The default list is:

```
.SUFFIXES: .o .c .c~ .y .y~ .l .l~ .s .s~ .sh .sh~ .h .h~ .f .f~ .C
.C~ .Y .Y~ .L .L~
```

Here again, the above command for printing the internal rules will display the list of suffixes implemented on the current machine. Multiple suffix lists accumulate; `.SUFFIXES:` with no dependencies clears the list of suffixes.

Inference Rules

The first example can be done more briefly.

```
pgm: a.o b.o
      cc a.o b.o -o pgm
a.o b.o: incl.h
```

This abbreviation is possible because make has a set of internal rules for building files. The user may add rules to this list by simply putting them in the *makefile*.

Certain macros are used by the default inference rules to permit the inclusion of optional matter in any resulting commands. For example, `CFLAGS`, `LFLAGS`, and `YFLAGS` are used for compiler options to `cc(1B)`. Again, the previous method for examining the current rules is recommended.

The inference of prerequisites can be controlled. The rule to create a file with suffix `.o` from a file with suffix `.c` is specified as an entry with `.c.o:` as the target and no dependents. Shell commands associated with the target define the rule for making a `.o` file from a `.c` file. Any target that has no slashes in it and starts with a dot is identified as a rule and not a true target.

Libraries

If a target or dependency name contains parentheses, it is assumed to be an archive library, the string within parentheses referring to a member within the library. Thus, `lib(file.o)` and `$(LIB) (file.o)` both refer to an archive library that contains `file.o`. (This example assumes the `LIB` macro has been previously defined.) The expression `$(LIB) (file1.o file2.o)` is not legal. Rules pertaining to archive libraries have the form `.XX.a` where the `XX` is the suffix from which the archive member is to be made. An unfortunate by-product of the current implementation requires the `XX` to be different from the suffix of the archive member. Thus, one cannot have `lib(file.o)` depend upon `file.o` explicitly. The most common use of the archive interface follows. Here, we assume the source files are all C type source:

```
lib:    lib(file1.o) lib(file2.o) lib(file3.o)
        @echo lib is now up-to-date
.c.a:
        $(CC) -c $(CFLAGS) $<
        $(AR) $(ARFLAGS) $@ $*.o
        rm -f $*.o
```

In fact, the `.c.a` rule listed above is built into `make` and is unnecessary in this example. A more interesting, but more limited example of an archive library maintenance construction follows:

```
lib:    lib(file1.o) lib(file2.o) lib(file3.o)
        $(CC) -c $(CFLAGS) $(?:.o=.c)
        $(AR) $(ARFLAGS) lib $?
        rm $?
        @echo lib is now up-to-date
.c.a:;
```

Here the substitution mode of the macro expansions is used. The `$?` list is defined to be the set of object filenames (inside `lib`) whose C source files are outdated. The substitution mode translates the `.o` to `.c`. (Unfortunately, one cannot as yet transform to `.c~`; however, this transformation may become possible in the future.) Also note the disabling of the `.c.a:` rule, which would have created each object file, one by one. This particular construct speeds up archive library maintenance considerably. This type of construct becomes very cumbersome if the archive library contains a mix of assembly programs and C programs.

ENVIRONMENT VARIABLES

`USE_SVR4_MAKE` If this environment variable is set, then the `make` command will invoke this System V version of `make`. If this variable is not set, then the default version of `make(1S)` is invoked.

`USE_SVR4_MAKE` can be set as follows (Bourne shell):

```
$ USE_SVR4_MAKE='''; export USE_SVR4_MAKE
```

or (C shell):

```
% setenv USE_SVR4_MAKE
```

FILES [Mm]akefile
 s. [Mm]akefile
 default makefiles

/usr/bin/sh
 default shell for make

/usr/share/lib/make/make.rules
 default rules for make

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

SEE ALSO `cc(1B)`, `cd(1)`, `make(1S)`, `sh(1)`, `printf(3C)`, `sccsfile(4)`, `attributes(5)`

NOTES Some commands return non-zero status inappropriately; use `-i` or the `'-'` command line prefix to overcome the difficulty.

Filenames containing the characters `'='`, `':'`, and `'@'` will not work. Commands that are directly executed by the shell, notably `cd(1)`, are ineffectual across NEWLINES in `make`. The syntax `lib(file1.o file2.o file3.o)` is illegal. You cannot build `lib(file.o)` from `file.o`.

	-c2	1, 6, 10, 14, 49	COBOL compact format (columns 1-6 omitted). Using this code, the first typed character corresponds to card column 7, one space gets you to column 8, and a tab reaches column 12. Files using this tab setup should include a format specification as follows (see <code>fspec(4)</code>): <code><:t-c2 m6 s66 d:></code>
	-c3	1, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62, 67	COBOL compact format (columns 1-6 omitted), with more tabs than <code>-c2</code> . This is the recommended format for COBOL. The appropriate format specification is (see <code>fspec(4)</code>): <code><:t-c3 m6 s66 d:></code>
	-f	1, 7, 11, 15, 19, 23	FORTRAN
	-p	1, 5, 9, 13, 17, 21, 25, 29, 33, 37, 41, 45, 49, 53, 57, 61	PL/I
	-s	1, 10, 55	SNOBOL
	-u	1, 12, 20, 44	UNIVAC 1100 Assembler
<i>Repetitive</i>	-n		A <i>repetitive</i> specification requests tabs at columns $1+n$, $1+2*n$, etc., where n is a single-digit decimal number. Of particular importance is the value 8: this represents the UNIX system "standard" tab setting, and is the most likely tab setting to be found at a terminal. When <code>-0</code> is used, the tab stops are cleared and no new ones are set.
<i>Arbitrary</i>			See OPERANDS.
<i>File</i>	-file		If the name of a <i>file</i> is given, <code>tabs</code> reads the first line of the file, searching for a format specification (see <code>fspec(4)</code>). If it finds one there, it sets the tab stops according to it, otherwise it sets them as <code>-8</code> . This type of specification may be used to make sure that a tabbed file is printed with correct tab settings, and would be used with the <code>pr</code> command: <code>example% tabs -file; pr file</code>
			Tab and margin setting is performed via the standard output.

tabs(1)

- OPERANDS** The following operand is supported:
- n1*[,*n2*, . . .] The *arbitrary* format consists of tab-stop values separated by commas or spaces. The tab-stop values must be positive decimal integers in ascending order. Up to 40 numbers are allowed. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. Thus, the formats 1,10,20,30, and 1,10,+10,+10 are considered identical.
- EXAMPLES**
- EXAMPLE 1** Using the tabs command
- The following command is an example using *-code* (*canned* specification) to set tabs to the settings required by the IBM assembler: columns 1, 10, 16, 36, 72:
- ```
example% tabs -a
```
- The next command is an example of using *-n* (*repetitive* specification), where *n* is 8, causes tabs to be set every eighth position: 1+(1\*8), 1+(2\*8), . . . which evaluate to columns 9, 17, . . . :
- ```
example% tabs -8
```
- This command uses *n1,n2,. . .* (*arbitrary* specification) to set tabs at columns 1, 8, and 36:
- ```
example% tabs 1,8,36
```
- The last command is an example of using *-file* (*file* specification) to indicate that tabs should be set according to the first line of `$HOME/fspec.list/att4425` (see `fspec(4)`).
- ```
example% tabs -$HOME/fspec.list/att4425
```
- ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `tabs`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.
- TERM** Determine the terminal type. If this variable is unset or null, and if the `-T` option is not specified, terminal type `ansi+tabs` will be used.
- EXIT STATUS** The following exit values are returned:
- 0 Successful completion.
- >0 An error occurred.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard

SEE ALSO `expand(1)`, `newform(1)`, `pr(1)`, `stty(1)`, `tput(1)`, `fspec(4)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `term(5)`, `standards(5)`

NOTES There is no consistency among different terminals regarding ways of clearing tabs and setting the left margin.

`tabs` clears only 20 tabs (on terminals requiring a long sequence), but is willing to set 64.

The *tabspec* used with the `tabs` command is different from the one used with the `newform` command. For example, `tabs -8` sets every eighth position; whereas `newform -i-8` indicates that tabs are set every eighth position.

tail(1)

NAME	tail – deliver the last part of a file
SYNOPSIS	<pre>/usr/bin/tail [+ number [lbcrl]] [file] /usr/bin/tail [-lbcrl] [file] /usr/bin/tail [+ number [lbcfl]] [file] /usr/bin/tail [-lbcfl] [file] /usr/xpg4/bin/tail [-f -r] [-c number -n number] [file] /usr/xpg4/bin/tail [+ number [l b c] [fl]] [file] /usr/xpg4/bin/tail [+ number [l] [f r]] [file]</pre>
DESCRIPTION	<p>The <code>tail</code> utility copies the named file to the standard output beginning at a designated place. If no file is named, the standard input is used.</p> <p>Copying begins at a point in the file indicated by the <code>-cnumber</code>, <code>-nnumber</code>, or <code>±number</code> options (if <code>+number</code> is specified, begins at distance number from the beginning; if <code>-number</code> is specified, from the end of the input; if <code>number</code> is NULL, the value 10 is assumed). <code>number</code> is counted in units of lines or byte according to the <code>-c</code> or <code>-n</code> options, or lines, blocks, or bytes, according to the appended option <code>l</code>, <code>b</code>, or <code>c</code>. When no units are specified, counting is by lines.</p>
OPTIONS	<p>The following options are supported for both <code>/usr/bin/tail</code> and <code>/usr/xpg4/bin/tail</code>. The <code>-r</code> and <code>-f</code> options are mutually exclusive. If both are specified on the command line, the <code>-f</code> option will be ignored.</p> <ul style="list-style-type: none"><code>-b</code> Units of blocks.<code>-c</code> Units of bytes.<code>-f</code> Follow. If the input-file is not a pipe, the program will not terminate after the line of the input-file has been copied, but will enter an endless loop, wherein it sleeps for a second and then attempts to read and copy further records from the input-file. Thus it may be used to monitor the growth of a file that is being written by some other process.<code>-l</code> Units of lines.<code>-r</code> Reverse. Copies lines from the specified starting point in the file in reverse order. The default for <code>r</code> is to print the entire file in reverse order.
/usr/xpg4/bin/tail	<p>The following options are supported for <code>/usr/xpg4/bin/tail</code> only:</p> <ul style="list-style-type: none"><code>-c number</code> The <code>number</code> option-argument must be a decimal integer whose sign affects the location in the file, measured in bytes, to begin the copying:<ul style="list-style-type: none"><code>+</code> Copying starts relative to the beginning of the file.<code>-</code> Copying starts relative to the end of the file.<code>none</code> Copying starts relative to the end of the file.

The origin for counting is 1; that is, `-c+1` represents the first byte of the file, `-c-1` the last.

`-n number` Equivalent to `-cnumber`, except the starting location in the file is measured in lines instead of bytes. The origin for counting is 1. That is, `-n+1` represents the first line of the file, `-n-1` the last.

OPERANDS The following operand is supported:

file A path name of an input file. If no *file* operands are specified, the standard input will be used.

USAGE See `largefile(5)` for the description of the behavior of `tail` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Using the tail Command

The following command will print the last ten lines of the file `fred`, followed by any lines that are appended to `fred` between the time `tail` is initiated and killed.

```
example% tail -f fred
```

The next command will print the last 15 bytes of the file `fred`, followed by any lines that are appended to `fred` between the time `tail` is initiated and killed:

```
example% tail -15cf fred
```

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `tail`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/tail`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

`/usr/xpg4/bin/tail`

NOTES | Piped tails relative to the end of the file are stored in a buffer, and thus are limited in
length. Various kinds of anomalous behavior may happen with character special files.

NAME	talk – talk to another user
SYNOPSIS	talk <i>address</i> [<i>terminal</i>]
DESCRIPTION	<p>The <code>talk</code> utility is a two-way, screen-oriented communication program.</p> <p>When first invoked, <code>talk</code> sends a message similar to:</p> <pre>Message from TalkDaemon@ her_machine at time... talk: connection requested by your_address talk: respond with: talk your_address</pre> <p>to the specified <i>address</i>. At this point, the recipient of the message can reply by typing:</p> <pre>talk your_address</pre> <p>Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters are processed as follows:</p> <ul style="list-style-type: none"> ■ Typing the alert character will alert the recipient's terminal. ■ Typing Control-L will cause the sender's screen regions to be refreshed. ■ Typing the erase and kill characters will affect the sender's terminal in the manner described by the <code>termios(3C)</code> interface. ■ Typing the interrupt or end-of-file (EOF) characters will terminate the local <code>talk</code> utility. Once the <code>talk</code> session has been terminated on one side, the other side of the <code>talk</code> session will be notified that the <code>talk</code> session has been terminated and will be able to do nothing except exit. ■ Typing characters from <code>LC_CTYPE</code> classifications <code>print</code> or <code>space</code> will cause those characters to be sent to the recipient's terminal. ■ When and only when the <code>stty iexten</code> local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable. ■ Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a caret (<code>^</code>) followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, <code>'\003'</code> is displayed as <code>'^C'</code> and <code>'\372'</code> as <code>'M-z'</code>. <p>Permission to be a recipient of a <code>talk</code> message can be denied or granted by use of the <code>mesg(1)</code> utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. Certain commands, such as <code>pr(1)</code>, disallow messages in order to prevent interference with their output. <code>talk</code> will fail when the user lacks the appropriate privileges to perform the requested action.</p>

talk(1)

Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for `talk`. When this type of exchange cannot be supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.

OPERANDS The following operands are supported:

address The recipient of the `talk` session. One form of *address* is the *username*, as returned by the `who(1)` utility. If you wish to talk to someone on your own machine, then *username* is just the person's login name. If you wish to talk to a user on another host, then *username* is one of the following forms:

```
host!user
host.user
host:user
user@host
```

although *user@host* is perhaps preferred.

terminal If the recipient is logged in more than once, *terminal* can be used to indicate the appropriate terminal name. If *terminal* is not specified, the `talk` message will be displayed on one or more accessible terminals in use by the recipient. The format of *terminal* will be the same as that returned by `who`.

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `talk`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

TERM Determine the name of the invoker's terminal type. If this variable is unset or null, an unspecified terminal type will be used.

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred, or `talk` was invoked on a terminal incapable of supporting it.

FILES `/etc/hosts` host name database
`/var/adm/utmpx` user and accounting information for `talk`

NOTES Typing Control-L redraws the screen, while the erase, kill, and word kill characters will work in talk as normal. To exit, type an interrupt character. talk then moves the cursor to the bottom of the screen and restores the terminal to its previous state.

tar(1)

NAME	tar – create tape archives and add or extract files
SYNOPSIS	<pre>tar c [bBeEfFhiklnopPqvwX@ [0-7]] [block] [tarfile] [exclude-file] {-I include-file -C directory file file...} tar r [bBeEfFhiklnqvw@ [0-7]] [block] {-I include-file -C directory file file...} tar t [BefFhiklnqvX [0-7]] [tarfile] [exclude-file] {-I include-file file...} tar u [bBeEfFhiklnqvw@ [0-7]] [block] [tarfile] file... tar x [BefFhiklmnopqvwX [0-7]] [tarfile] [exclude-file] [file...]</pre>
DESCRIPTION	<p>The tar command archives and extracts files to and from a single file called a <i>tarfile</i>. A <i>tarfile</i> is usually a magnetic tape, but it can be any file. tar's actions are controlled by the <i>key</i> argument. The <i>key</i> is a string of characters containing exactly one function letter (c, r, t, u, or x) and zero or more function modifiers (letters or digits), depending on the function letter used. The <i>key</i> string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the <i>key</i> string.</p> <p>The <i>-I include-file</i>, <i>-C directory file</i>, and <i>file</i> arguments specify which files or directories are to be archived or extracted. In all cases, appearance of a directory name refers to the files and (recursively) subdirectories of that directory. Arguments appearing within braces ({ }) indicate that one of the arguments must be specified.</p>
OPTIONS	<p>The following options are supported:</p> <p><i>-I include-file</i> Opens <i>include-file</i> containing a list of files, one per line, and treats it as if each file appeared separately on the command line. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the included file, the entire line (apart from the newline) will be used to match against the initial string of files to include. In the case where excluded files (see X function modifier) are also specified, they take precedence over all included files. If a file is specified in both the <i>exclude-file</i> and the <i>include-file</i> (or on the command line), it will be excluded.</p> <p><i>-C directory file</i> Performs a <i>chdir</i> (see <i>cd(1)</i>) operation on <i>directory</i> and performs the <i>c</i> (create) or <i>r</i> (replace) operation on <i>file</i>. Use short relative path names for <i>file</i>. If <i>file</i> is '.', archive all files in <i>directory</i>. This option enables archiving files from multiple directories not related by a close common parent.</p>
OPERANDS	The following operands are supported:

file A path name of a regular file or directory to be archived (when the *c*, *r* or *u* functions are specified), extracted (*x*) or listed (*t*). When *file* is the path name of a directory, the action applies to all of the files and (recursively) subdirectories of that directory.

When a file is archived, and the *E* flag (see *Function Modifiers*) is not specified, the filename cannot exceed 256 characters. In addition, it must be possible to split the name between parent directory names so that the prefix is no longer than 155 characters and the name is no longer than 100 characters. If *E* is specified, a name of up to `PATH_MAX` characters may be specified.

For example, a file whose basename is longer than 100 characters could not be archived without using the *E* flag. A file whose directory portion is 200 characters and whose basename is 50 characters could be archived (without using *E*) if a slash appears in the directory name somewhere in character positions 151-156.

Function Letters

The function portion of the key is specified by one of the following letters:

- c* Create. Writing begins at the beginning of the tarfile, instead of at the end.
- r* Replace. The named *files* are written at the end of the tarfile. A file created with extended headers must be updated with extended headers (see *E* flag under *Function Modifiers*). A file created without extended headers cannot be modified with extended headers.
- t* Table of Contents. The names of the specified files are listed each time they occur in the tarfile. If no *file* argument is given, the names of all files and any associated extended attributes in the tarfile are listed. With the *v* function modifier, additional information for the specified files is displayed.
- u* Update. The named *files* are written at the end of the tarfile if they are not already in the tarfile, or if they have been modified since last written to that tarfile. An update can be rather slow. A tarfile created on a 5.x system cannot be updated on a 4.x system. A file created with extended headers must be updated with extended headers (see *E* flag under *Function Modifiers*). A file created without extended headers cannot be modified with extended headers.
- x* Extract or restore. The named *files* are extracted from the tarfile and written to the directory specified in the tarfile, relative to the current directory. Use the relative path names of files and directories to be extracted.

Absolute path names contained in the tar archive are unpacked using the absolute path names, that is, the leading forward slash (/) is *not* stripped off.

tar(1)

If a named file matches a directory whose contents has been written to the tarfile, this directory is recursively extracted. The owner, modification time, and mode are restored (if possible); otherwise, to restore owner, you must be the super-user. Character-special and block-special devices (created by `mknod(1M)`) can only be extracted by the super-user. If no *file* argument is given, the entire content of the tarfile is extracted. If the tarfile contains several files with the same name, each file is written to the appropriate directory, overwriting the previous one. Filename substitution wildcards cannot be used for extracting files from the archive. Rather, use a command of the form:

```
tar xvf ... /dev/rmt/0 `tar tf ... /dev/rmt/0 | \
  grep 'pattern'`
```

When extracting tapes created with the *r* or *u* functions, directory modification times may not be set correctly. These same functions cannot be used with many tape drives due to tape drive limitations such as the absence of backspace or append capabilities.

When using the *r*, *u*, or *x* functions or the *X* function modifier, the named files must match exactly the corresponding files in the *tarfile*. For example, to extract *./thisfile*, you must specify *./thisfile*, and not *thisfile*. The *t* function displays how each file was archived.

Function Modifiers

The characters below may be used in conjunction with the letter that selects the desired function.

b Blocking Factor. Use when reading or writing to raw magnetic archives (see *f* below). The *block* argument specifies the number of 512-byte tape blocks to be included in each read or write operation performed on the tarfile. The minimum is 1, the default is 20. The maximum value is a function of the amount of memory available and the blocking requirements of the specific tape device involved (see `mtio(7I)` for details.) The maximum cannot exceed `INT_MAX/512 (4194303)`.

When a tape archive is being read, its actual blocking factor will be automatically detected, provided that it is less than or equal to the nominal blocking factor (the value of the *block* argument, or the default value if the *b* modifier is not specified). If the actual blocking factor is greater than the nominal blocking factor, a read error will result. See Example 5 in EXAMPLES.

B Block. Force `tar` to perform multiple reads (if necessary) to read exactly enough bytes to fill a block. This function modifier enables `tar` to work across the Ethernet, since pipes and sockets return partial blocks even when more data is coming. When reading from standard input, *'-'*, this function modifier is selected by default to ensure that `tar` can recover from short reads.

e	Error. Exit immediately with a positive exit status if any unexpected errors occur. The <code>SYSV3</code> environment variable overrides the default behavior. (See ENVIRONMENT VARIABLES section below.)
E	Write a tarfile with extended headers. (Used with <code>c</code> , <code>r</code> , or <code>u</code> options; ignored with <code>t</code> or <code>x</code> options.) When a tarfile is written with extended headers, the modification time is maintained with a granularity of microseconds rather than seconds. In addition, filenames no longer than <code>PATH_MAX</code> characters that could not be archived without <code>E</code> , and file sizes greater than 8GB, are supported. The <code>E</code> flag is required whenever the larger files and/or files with longer names, or whose <code>UID/GID</code> exceed 2097151, are to be archived, or if time granularity of microseconds is desired.
f	File. Use the <i>tarfile</i> argument as the name of the tarfile. If <code>f</code> is specified, <code>/etc/default/tar</code> is not searched. If <code>f</code> is omitted, <code>tar</code> will use the device indicated by the <code>TAPE</code> environment variable, if set; otherwise, it will use the default values defined in <code>/etc/default/tar</code> . The number matching the <code>archiveN</code> string is used as the output device with the blocking and size specifications from the file. For example, <pre style="margin-left: 20px;">tar -c 2/tmp/*</pre> <p>writes the output to the device specified as <code>archive2</code> in <code>/etc/default/tar</code>.</p> <p>If the name of the tarfile is <code>'-'</code>, <code>tar</code> writes to the standard output or reads from the standard input, whichever is appropriate. <code>tar</code> can be used as the head or tail of a pipeline. <code>tar</code> can also be used to move hierarchies with the command:</p> <pre style="margin-left: 20px;">example% cd fromdir; tar cf - . (cd todir; tar xfbp -)</pre>
F	With one <code>F</code> argument, <code>tar</code> excludes all directories named <code>SCCS</code> and <code>RCS</code> from the tarfile. With two arguments, <code>FF</code> , <code>tar</code> excludes all directories named <code>SCCS</code> and <code>RCS</code> , all files with <code>.o</code> as their suffix, and all files named <code>errs</code> , <code>core</code> , and <code>a.out</code> . The <code>SYSV3</code> environment variable overrides the default behavior. (See ENVIRONMENT VARIABLES section below.)
h	Follow symbolic links as if they were normal files or directories. Normally, <code>tar</code> does not follow symbolic links.
i	Ignore directory checksum errors.
k <i>size</i>	Requires <code>tar</code> to use the <code>size</code> argument as the size of an archive in kilobytes. This is useful when the archive is intended for a fixed size device such as floppy disks. Large files are then split across volumes if they do not fit in the specified size.

tar(1)

l	Link. Output error message if unable to resolve all links to the files being archived. If l is not specified, no error messages are printed.
m	Modify. The modification time of the file is the time of extraction. This function modifier is valid only with the x function.
n	The file being read is a non-tape device. Reading of the archive is faster since tar can randomly seek around the archive.
o	Ownership. Assign to extracted files the user and group identifiers of the user running the program, rather than those on tarfile. This is the default behavior for users other than root. If the o function modifier is not set and the user is root, the extracted files will take on the group and user identifiers of the files on tarfile (see <code>chown(1)</code> for more information). The o function modifier is only valid with the x function.
p	Restore the named files to their original modes, and ACLs if applicable, ignoring the present <code>umask(1)</code> . This is the default behavior if invoked as super-user with the x function letter specified. If super-user, SETUID, and sticky information are also extracted, and files are restored with their original owners and permissions, rather than owned by root. When this function modifier is used with the c function, ACLs are created in the tarfile along with other information. Errors will occur when a tarfile with ACLs is extracted by previous versions of tar.
P	Suppress the addition of a trailing "/" on directory entries in the archive.
q	Stop after extracting the first occurrence of the named file. tar will normally continue reading the archive after finding an occurrence of a file.
v	Verbose. Output the name of each file preceded by the function letter. With the t function, v provides additional information about the tarfile entries. The listing is similar to the format produced by the -l option of the <code>ls(1)</code> command.
w	What. Output the action to be taken and the name of the file, then await the user's confirmation. If the response is affirmative, the action is performed; otherwise, the action is not performed. This function modifier cannot be used with the t function.
X	Exclude. Use the <i>exclude-file</i> argument as a file containing a list of relative path names for files (or directories) to be excluded from the tarfile when using the functions c, x, or t. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the excluded file, the entire line (apart from the newline) will be used to match against the initial string of files to exclude. Multiple X arguments may be used, with one <i>exclude-file</i> per

argument. In the case where included files (see `-I include-file` option) are also specified, the excluded files take precedence over all included files. If a file is specified in both the `exclude-file` and the `include-file` (or on the command line), it will be excluded.

@ Include extended attributes in archive. By default, `tar` does not place extended attributes in the archive. With this flag, `tar` will look for extended attributes on the files to be placed in the archive and add them to the archive. Extended attributes go in the archive as special files with a special type label. When this modifier is used with the `x` function, extended attributes are extracted from the tape along with the normal file data. Extended attribute files can only be extracted from an archive as part of a normal file extract. Attempts to explicitly extract attribute records are ignored.

[0-7] Select an alternative drive on which the tape is mounted. The default entries are specified in `/etc/default/tar`. If no digit or `f` function modifier is specified, the entry in `/etc/default/tar` with digit "0" is the default.

USAGE See `largefile(5)` for the description of the behavior of `tar` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

The automatic determination of the actual blocking factor may be fooled when reading from a pipe or a socket (see the `B` function modifier below).

1/4" streaming tape has an inherent blocking factor of one 512-byte block. It can be read or written using any blocking factor.

This function modifier works for archives on disk files and block special devices, among others, but is intended principally for tape devices.

For information on `tar` header format, see `archives(4)`.

EXAMPLES **EXAMPLE 1** Creating an archive of your home directory

The following is an example using `tar` to create an archive of your home directory on a tape mounted on drive `/dev/rmt/0`:

```
example% cd
example% tar cvf /dev/rmt/0 .
messages from tar
```

The `c` function letter means create the archive. The `v` function modifier outputs messages explaining what `tar` is doing. The `f` function modifier indicates that the tarfile is being specified (`/dev/rmt/0` in this example). The dot (`.`) at the end of the command line indicates the current directory and is the argument of the `f` function modifier.

Display the table of contents of the tarfile with the following command:

tar(1)

EXAMPLE 1 Creating an archive of your home directory (Continued)

```
example% tar tvf /dev/rmt/0
```

The output will be similar to the following for the POSIX locale:

```
rw-r--r--  1677/40   2123   Nov  7 18:15 1985   ./test.c
...
```

The columns have the following meanings:

- column 1 is the access permissions to `./test.c`
- column 2 is the *user-id/group-id* of `./test.c`
- column 3 is the size of `./test.c` in bytes
- column 4 is the modification date of `./test.c`. When the `LC_TIME` category is not set to the POSIX locale, a different format and date order field may be used.
- column 5 is the name of `./test.c`

To extract files from the archive:

```
example% tar xvf /dev/rmt/0
messages from tar
example%
```

If there are multiple archive files on a tape, each is separated from the following one by an EOF marker. To have `tar` read the first and second archives from a tape with multiple archives on it, the *non-rewinding* version of the tape device name must be used with the `f` function modifier, as follows:

```
example% tar xvfp /dev/rmt/0n read first archive from tape
messages from tar
example% tar xvfp /dev/rmt/0n read second archive from tape
messages from tar
example%
```

Notice that in some earlier releases, the above scenario did not work correctly, and intervention with `mt(1)` between `tar` invocations was necessary. To emulate the old behavior, use the non-rewind device name containing the letter `b` for BSD behavior. See the *Close Operations* section of the `mtio(7I)` manual page.

EXAMPLE 2 Archiving files from `/usr/include` and from `/etc` to default tape drive 0

To archive files from `/usr/include` and from `/etc` to default tape drive 0:

```
example% tar c -C /usr include -C /etc .
```

The table of contents from the resulting tarfile would produce output like the following:

EXAMPLE 2 Archiving files from /usr/include and from /etc to default tape drive 0
(Continued)

```
include/
include/a.out.h
and all the other files in /usr/include ...
./chown and all the other files in /etc
```

To extract all files in the include directory:

```
example% tar xv include
x include/, 0 bytes, 0 tape blocks \
  and all files under include ...
```

EXAMPLE 3 Transferring files across the network

The following is an example using tar to transfer files across the network. First, here is how to archive files from the local machine (example) to a tape on a remote system (host):

```
example% tar cvfb - 20 files | \
  rsh host dd of=/dev/rmt/0 obs=20b
messages from tar
example%
```

In the example above, we are *creating a tarfile* with the *c* key letter, asking for *verbose* output from tar with the *v* function modifier, specifying the name of the output *tarfile* using the *f* function modifier (the standard output is where the *tarfile* appears, as indicated by the '-' sign), and specifying the blocksize (20) with the *b* function modifier. If you want to change the blocksize, you must change the blocksize arguments both on the tar command *and* on the dd command.

EXAMPLE 4 Retrieving files from a tape on the remote system back to the local system

The following is an example that uses tar to retrieve files from a tape on the remote system back to the local system:

```
example% rsh -n host dd if=/dev/rmt/0 bs=20b | \
  tar xvBfb - 20 files
messages from tar
example%
```

In the example above, we are *extracting* from the *tarfile* with the *x* key letter, asking for *verbose output* from tar with the *v* function modifier, telling tar it is reading from a pipe with the *B* function modifier, specifying the name of the input *tarfile* using the *f* function modifier (the standard input is where the *tarfile* appears, as indicated by the '-' sign), and specifying the blocksize (20) with the *b* function modifier.

tar(1)

EXAMPLE 5 Creating an archive of the home directory

The following example creates an archive of the home directory on `/dev/rmt/0` with an actual blocking factor of 19:

```
example% tar cvfb /dev/rmt/0 19 $HOME
```

To recognize this archive's actual blocking factor without using the `b` function modifier:

```
example% tar tvf /dev/rmt/0
tar: blocksize = 19
...
```

To recognize this archive's actual blocking factor using a larger nominal blocking factor:

```
example% tar tvf /dev/rmt/0 30
tar: blocksize = 19
...
```

Attempt to recognize this archive's actual blocking factor using a nominal blocking factor that is too small:

```
example% tar tvf /dev/rmt/0 10
tar: tape read error
```

ENVIRONMENT VARIABLES

SYSV3 This variable is used to override the default behavior of `tar`, provide compatibility with INTERACTIVE UNIX Systems and SCO UNIX installation scripts, and should not be used in new scripts. (It is intended for compatibility purposes only.) When set, the following options behave differently:

- `-F filename` Uses *filename* to obtain a list of command line switches and files on which to operate.
- `-e` Prevents files from being split across volumes. If there is insufficient room on one volume, `tar` prompts for a new volume. If the file will not fit on the new volume, `tar` exits with an error.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tar`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

FILES /dev/rmt/[0-7] [b] [n]
 /dev/rmt/[0-7]l [b] [n]
 /dev/rmt/[0-7]m [b] [n]
 /dev/rmt/[0-7]h [b] [n]
 /dev/rmt/[0-7]u [b] [n]
 /dev/rmt/[0-7]c [b] [n]
 /etc/default/tar

Settings may look like this:

```
archive0=/dev/rmt/0
archive1=/dev/rmt/0n
archive2=/dev/rmt/1
archive3=/dev/rmt/1n
archive4=/dev/rmt/0
archive5=/dev/rmt/0n
archive6=/dev/rmt/1
archive7=/dev/rmt/1n
```

/tmp/tar*

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

SEE ALSO ar(1), basename(1), cd(1), chown(1), cpio(1), csh(1), dirname(1), ls(1), mt(1), pax(1), setfacl(1), umask(1), mknod(1M), vold(1M), archives(4), attributes(5), environ(5), fsattr(5), largefile(5), mtio(7I)

DIAGNOSTICS Diagnostic messages are output for bad key characters and tape read/write errors, and for insufficient memory to hold the link tables.

NOTES There is no way to access the *n*-th occurrence of a file.

Tape errors are handled ungracefully.

When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (for example, /dev/rdiskette) may not succeed. See vold(1M) for further details.

tar(1)

The `tar` archive format allows UIDs and GIDs up to 2097151 to be stored in the archive header. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.

If an archive is created that contains files whose names were created by processes running in multiple locales, a single locale that uses a full 8-bit codeset (for example, the `en_US` locale) should be used both to create the archive and to extract files from the archive.

Neither the `-r` option nor the `-u` option can be used with quarter-inch archive tapes, since these tape drives cannot backspace.

NAME tbl – format tables for nroff or troff

SYNOPSIS **tbl** [-me] [-mm] [-ms] [*filename*]...

DESCRIPTION tbl is a preprocessor for formatting tables for nroff(1) or troff(1). The input *filenames* are copied to the standard output, except that lines between .TS and .TE command lines are assumed to describe tables and are reformatted.

If no arguments are given, tbl reads the standard input, so tbl may be used as a filter. When tbl is used with eqn(1) or neqn, the tbl command should be first, to minimize the volume of data passed through pipes.

OPTIONS

- me Copy the -me macro package to the front of the output file.
- mm Copy the -mm macro package to the front of the output file.
- ms Copy the -ms macro package to the front of the output file.

EXAMPLES **EXAMPLE 1** Using tbl

As an example, letting '@' (at-sign) represent a TAB, which should be typed as an actual TAB character in the input file

```
.TS
c s s
c c s
c c c
l n n.
Household Population
Town@Households
@Number@Size
Bedminster@789@3.26
Bernards Twp.@3087@3.74
Bernardsville@2018@3.30
Bound Brook@3425@3.04
Branchburg@1644@3.49
.TE
```

yields

```
Household Population

Town                               Households

                                   Number           Size

Bedminster                         789           3.26
Bernards Twp.                      3087          3.74
Bernardsville                      2018          3.30
Bound Brook                        3425          3.04
Branchburg                          1644          3.49
```

NAME	tcopy – copy a magnetic tape				
SYNOPSIS	tcopy <i>source</i> [<i>destination</i>]				
DESCRIPTION	<p>The <code>tcopy</code> utility copies the magnetic tape mounted on the tape drive specified by the <code>source</code> argument. The only assumption made about the contents of a tape is that there are two tape marks at the end.</p> <p>When only a source drive is specified, <code>tcopy</code> scans the tape, and displays information about the sizes of records and tape files. If a destination is specified, <code>tcopy</code> makes a copies the source tape onto the <i>destination</i> tape, with blocking preserved. As it copies, <code>tcopy</code> produces the same output as it does when only scanning a tape.</p> <p>The <code>tcopy</code> utility requires the use of Berkeley-compatible device names. For example,</p> <pre>example% tcopy /dev/rmt/1b /dev/rmt/2b</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWesu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWesu				
SEE ALSO	<code>mt(1)</code> , <code>ioctl(2)</code> , <code>attributes(5)</code>				
NOTES	<code>tcopy</code> will only run on systems supporting an associated set of <code>ioctl(2)</code> requests.				

tee(1)

NAME | tee – replicate the standard output

SYNOPSIS | **tee** [-ai] [*file*...]

DESCRIPTION | The **tee** utility will copy standard input to standard output, making a copy in zero or more files. **tee** will not buffer its output. The options determine if the specified files are overwritten or appended to.

OPTIONS | The following options are supported.

- a Appends the output to the files rather than overwriting them.
- i Ignores interrupts.

OPERANDS | The following operands are supported:

file A path name of an output file. Processing of at least 13 *file* operands will be supported.

USAGE | See **largefile(5)** for the description of the behavior of **tee** when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

ENVIRONMENT VARIABLES | See **environ(5)** for descriptions of the following environment variables that affect the execution of **tee**: **LANG**, **LC_ALL**, **LC_CTYPE**, **LC_MESSAGES**, and **NLSPATH**.

EXIT STATUS | The following exit values are returned:

- 0 The standard input was successfully copied to all output files.
- >0 The number of files that could not be opened or whose status could not be obtained.

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Standard

SEE ALSO | **cat(1)**, **attributes(5)**, **environ(5)**, **largefile(5)**, **standards(5)**

NAME	telnet – user interface to a remote system using the TELNET protocol
SYNOPSIS	telnet [-8ELcdr] [-e <i>escape_char</i>] [-l <i>user</i>] [-n <i>file</i>] [[[!] @hop1 [@hop2...] @] <i>host</i> [<i>port</i>]]
DESCRIPTION	<p>The <code>telnet</code> utility communicates with another host using the TELNET protocol. If <code>telnet</code> is invoked without arguments, it enters command mode, indicated by its prompt, <code>telnet></code>. In this mode, it accepts and executes its associated commands. See USAGE, <code>telnet</code> Commands, below. If it is invoked with arguments, it performs an open command with those arguments.</p> <p>If, for example, a <i>host</i> is specified as <code>@hop1@hop2@host</code>, the connection goes through hosts <i>hop1</i> and <i>hop2</i>, using loose source routing to end at <i>host</i>. If a leading <code>!</code> is used, the connection follows strict source routing. Note that when <code>telnet</code> uses IPv6, it can only use loose source routing, and the connection ignores the <code>!</code>.</p> <p>Once a connection has been opened, <code>telnet</code> enters input mode. In this mode, text typed is sent to the remote host. The input mode entered will be either "line mode", "character at a time", or "old line by line", depending upon what the remote system supports.</p> <p>In "line mode", character processing is done on the local system, under the control of the remote system. When input editing or character echoing is to be disabled, the remote system will relay that information. The remote system will also relay changes to any special characters that happen on the remote system, so that they can take effect on the local system.</p> <p>In "character at a time" mode, most text typed is immediately sent to the remote host for processing.</p> <p>In "old line by line" mode, all text is echoed locally, and (normally) only completed lines are sent to the remote host. The "local echo character" (initially <code>^E</code>) may be used to turn off and on the local echo. (Use this mostly to enter passwords without the password being echoed.)</p> <p>If the "line mode" option is enabled, or if the <code>localchars</code> toggle is <code>TRUE</code> (the default in "old line by line" mode), the user's <code>quit</code>, <code>intr</code>, and <code>flush</code> characters are trapped locally, and sent as TELNET protocol sequences to the remote side. If "line mode" has ever been enabled, then the user's <code>susp</code> and <code>eof</code> are also sent as TELNET protocol sequences. <code>quit</code> is then sent as a TELNET ABORT instead of BREAK. The options <code>toggle autoflush</code> and <code>toggle autosynch</code> cause this action to flush subsequent output to the terminal (until the remote host acknowledges the TELNET sequence); and to flush previous terminal input, in the case of <code>quit</code> and <code>intr</code>.</p> <p>While connected to a remote host, the user can enter <code>telnet</code> command mode by typing the <code>telnet</code> escape character (initially <code>^]</code>). When in command mode, the normal terminal editing conventions are available. Pressing RETURN at the <code>telnet</code> command prompt causes <code>telnet</code> to exit command mode.</p>
OPTIONS	The following options are supported:

telnet(1)

-8	Specifies an 8-bit data path. Negotiating the TELNET BINARY option is attempted for both input and output.
-c	Disables the reading of the user's <code>telnetrc</code> file. (See the <code>toggle skiprc</code> command on this reference page.)
-d	Sets the initial value of the debug toggle to TRUE.
-e <i>escape_char</i>	Sets the initial escape character to <i>escape_char</i> . <i>escape_char</i> may also be a two character sequence consisting of '^' followed by one character. If the second character is '?', the DEL character is selected. Otherwise, the second character is converted to a control character and used as the escape character. If the escape character is the null string (that is, -e ''), it is disabled.
-E	Stops any character from being recognized as an escape character.
-l <i>user</i>	When connecting to a remote system that understands the ENVIRON option, then <i>user</i> will be sent to the remote system as the value for the ENVIRON variable USER.
-L	Specifies an 8-bit data path on output. This causes the BINARY option to be negotiated on output.
-n <i>tracefile</i>	Opens <i>tracefile</i> for recording trace information. See the <code>set tracefile</code> command below.
-r	Specifies a user interface similar to <code>rlogin</code> . In this mode, the escape character is set to the tilde (~) character, unless modified by the -e option. The <code>rlogin</code> escape character is only recognized when it is preceded by a carriage return. In this mode, the <code>telnet</code> escape character, normally '^]', must still precede a <code>telnet</code> command. The <code>rlogin</code> escape character can also be followed by '\r' or '^Z', and, like <code>rlogin(1)</code> , closes or suspends the connection, respectively. This option is an uncommitted interface and may change in the future.

telnet Commands

The commands described in this section are available with `telnet`. It is necessary to type only enough of each command to uniquely identify it. (This is also true for arguments to the `mode`, `set`, `toggle`, `unset`, `environ`, and `display` commands.)

`open [-l user] [[!] @hop1 [@hop2 ...]@host [port]`

Open a connection to the named host. If no port number is specified, `telnet` will attempt to contact a TELNET server at the default port. The host specification may be either a host name (see `hosts(4)`, `ipnodes(4)`) or an Internet address specified in the "dot notation" (see `inet(7P)` or `inet6(7P)`). If the *host* is specified as `@hop1@hop2@host`, the connection goes through hosts *hop1* and *hop2*, using loose source routing to end at *host*. The "@" symbol is required as a separator between the hosts specified. If a leading ! is used with IPv4, the connection follows strict source routing.

The `-l` option passes the *user* as the value of the ENVIRON variable USER to the remote system.

close

Close any open TELNET session and exit `telnet`. An EOF (in command mode) will also close a session and exit.

quit

Same as `close`.

z

Suspend `telnet`. This command only works when the user is using a shell that supports job control, such as `sh(1)`.

mode *type*

The remote host is asked for permission to go into the requested mode. If the remote host is capable of entering that mode, the requested mode will be entered. The argument *type* is one of the following:

character	Disable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then enter "character at a time" mode.
line	Enable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then attempt to enter "old-line-by-line" mode.
isig (-isig)	Attempt to enable (disable) the TRAPSIG mode of the LINEMODE option. This requires that the LINEMODE option be enabled.
edit (-edit)	Attempt to enable (disable) the EDIT mode of the LINEMODE option. This requires that the LINEMODE option be enabled.
softtabs (-softtabs)	Attempt to enable (disable) the SOFT_TAB mode of the LINEMODE option. This requires that the LINEMODE option be enabled.
litecho (-litecho)	Attempt to enable (disable) the LIT_ECHO mode of the LINEMODE option. This requires that the LINEMODE option be enabled.
?	Prints out help information for the mode command.

status

Show the current status of `telnet`. This includes the peer one is connected to, as well as the current mode.

display

[*argument . . .*] Display all, or some, of the set and toggle values (see `toggle argument . . .`).

telnet(1)

?

[*command*] Get help. With no arguments, `telnet` prints a help summary. If a command is specified, `telnet` will print the help information for just that command.

`send argument . . .`

Send one or more special character sequences to the remote host. The following are the arguments that can be specified (more than one argument may be specified at a time):

<code>escape</code>	Send the current <code>telnet</code> escape character (initially <code>^]</code>).
<code>synch</code>	Send the TELNET SYNCH sequence. This sequence discards all previously typed, but not yet read, input on the remote system. This sequence is sent as TCP urgent data and may not work if the remote system is a 4.2 BSD system. If it does not work, a lower case "r" may be echoed on the terminal.
<code>brk or break</code>	Send the TELNET BRK (Break) sequence, which may have significance to the remote system.
<code>ip</code>	Send the TELNET IP (Interrupt Process) sequence, which aborts the currently running process on the remote system.
<code>abort</code>	Send the TELNET ABORT (Abort Process) sequence.
<code>ao</code>	Send the TELNET AO (Abort Output) sequence, which flushes all output from the remote system to the user's terminal.
<code>ayt</code>	Send the TELNET AYT (Are You There) sequence, to which the remote system may or may not respond.
<code>ec</code>	Send the TELNET EC (Erase Character) sequence, which erases the last character entered.
<code>el</code>	Send the TELNET EL (Erase Line) sequence, which should cause the remote system to erase the line currently being entered.
<code>eof</code>	Send the TELNET EOF (End Of File) sequence.
<code>eor</code>	Send the TELNET EOR (End Of Record) sequence.
<code>ga</code>	Send the TELNET GA (Go Ahead) sequence, which probably has no significance for the remote system.
<code>getstatus</code>	If the remote side supports the TELNET STATUS command, <code>getstatus</code> will send the subnegotiation to request that the server send its current option status.
<code>nop</code>	Send the TELNET NOP (No Operation) sequence.
<code>susp</code>	Send the TELNET SUSP (Suspend Process) sequence.

do *option*
 dont *option*
 will *option*
 wont *option*

Send the TELNET protocol option negotiation indicated. Option may be the text name of the protocol option, or the number corresponding to the option. The command will be silently ignored if the option negotiation indicated is not valid in the current state. If the *option* is given as 'help' or '?', the list of option names known is listed. This command is mostly useful for unusual debugging situations.

? Print out help information for the send command.

set *argument* [*value*]

unset *argument*

Set any one of a number of telnet variables to a specific value. The special value "off" turns off the function associated with the variable. The values of variables may be interrogated with the display command. If *value* is omitted, the value is taken to be true, or "on". If the unset form is used, the value is taken to be false, or "off." The variables that may be specified are:

echo	This is the value (initially ^E) that, when in "line by line" mode, toggles between local echoing of entered characters for normal processing, and suppressing echoing of entered characters, for example, entering a password.
escape	This is the telnet escape character (initially ^]) that enters telnet command mode when connected to a remote system.
interrupt	If telnet is in localchars mode (see toggle, localchars) and the interrupt character is typed, a TELNET IP sequence (see send and ip) is sent to the remote host. The initial value for the interrupt character is taken to be the terminal's intr character.
quit	If telnet is in localchars mode and the quit character is typed, a TELNET BRK sequence (see send, brk) is sent to the remote host. The initial value for the quit character is taken to be the terminal's quit character.
flushoutput	If telnet is in localchars mode and the flushoutput character is typed, a TELNET AO sequence (see send, ao) is sent to the remote host. The initial value for the flush character is taken to be the terminal's flush character.
erase	If telnet is in localchars mode <i>and</i> operating in "character at a time" mode, then when the erase character is typed, a TELNET EC sequence (see send, ec) is sent to the remote system. The initial value for the erase character is taken to be the terminal's erase character.

telnet(1)

kill	If telnet is in localchars mode <i>and</i> operating in "character at a time" mode, then when the kill character is typed, a TELNET EL sequence (see send, e1) is sent to the remote system. The initial value for the kill character is taken to be the terminal's kill character.
eof	If telnet is operating in "line by line" mode, entering the eof character as the first character on a line sends this character to the remote system. The initial value of eof is taken to be the terminal's eof character.
ayt	If telnet is in localchars mode, or LINEMODE is enabled, and the status character is typed, a TELNET AYT ("Are You There") sequence is sent to the remote host. (See send, ayt above.) The initial value for ayt is the terminal's status character.
forw1 forw2	If telnet is operating in LINEMODE, and the forw1 or forw2 characters are typed, this causes the forwarding of partial lines to the remote system. The initial values for the forwarding characters come from the terminal's eol and eol2 characters.
lnext	If telnet is operating in LINEMODE or "old line by line" mode, then the lnext character is assumed to be the terminal's lnext character. The initial value for the lnext character is taken to be the terminal's lnext character.
reprint	If telnet is operating in LINEMODE or "old line by line" mode, then the reprint character is assumed to be the terminal's reprint character. The initial value for reprint is taken to be the terminal's reprint character.
rlogin	This is the rlogin escape character. If set, the normal telnet escape character is ignored, unless it is preceded by this character at the beginning of a line. The rlogin character, at the beginning of a line followed by a "." closes the connection. When followed by a ^Z, the rlogin command suspends the telnet command. The initial state is to disable the rlogin escape character.
start	If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the start character is taken to be the terminal's start character. The initial value for the kill character is taken to be the terminal's start character.
stop	If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the stop character is taken to be the terminal's stop character. The initial value for the kill character is taken to be the terminal's stop character.

<code>susp</code>	If <code>telnet</code> is in <code>localchars</code> mode, or <code>LINEMODE</code> is enabled, and the suspend character is typed, a TELNET SUSP sequence (see <code>send</code> , <code>susp</code> above) is sent to the remote host. The initial value for the suspend character is taken to be the terminal's suspend character.
<code>tracefile</code>	This is the file to which the output, generated when the <code>netdata</code> or the <code>debug</code> option is <code>TRUE</code> , will be written. If <code>tracefile</code> is set to "-", then tracing information will be written to standard output (the default).
<code>worderase</code>	If <code>telnet</code> is operating in <code>LINEMODE</code> or "old line by line" mode, then this character is taken to be the terminal's worderase character. The initial value for the worderase character is taken to be the terminal's worderase character.
<code>?</code>	Displays the legal set and unset commands.

slc state

The `slc` (Set Local Characters) command is used to set or change the state of special characters when the TELNET `LINEMODE` option has been enabled. Special characters are characters that get mapped to TELNET commands sequences (like `ip` or `quit`) or line editing characters (like `erase` and `kill`). By default, the local special characters are exported. The following values for `state` are valid:

<code>check</code>	Verifies the settings for the current special characters. The remote side is requested to send all the current special character settings. If there are any discrepancies with the local side, the local settings will switch to the remote values.
<code>export</code>	Switches to the local defaults for the special characters. The local default characters are those of the local terminal at the time when <code>telnet</code> was started.
<code>import</code>	Switches to the remote defaults for the special characters. The remote default characters are those of the remote system at the time when the TELNET connection was established.
<code>?</code>	Prints out help information for the <code>slc</code> command.

toggle argument . . .

Toggle between `TRUE` and `FALSE` the various flags that control how `telnet` responds to events. More than one argument may be specified. The state of these flags may be interrogated with the `display` command. Valid arguments are:

<code>autoflush</code>	If <code>autoflush</code> and <code>localchars</code> are both <code>TRUE</code> , then when the <code>ao</code> , <code>intr</code> , or <code>quit</code> characters are recognized (and transformed into TELNET sequences; see <code>set</code> for details), <code>telnet</code> refuses to display any data on the user's terminal until the remote system acknowledges (using a TELNET Timing Mark option) that it has processed those TELNET sequences. The initial value for this
------------------------	---

telnet(1)

	toggle is TRUE if the terminal user has not done an "stty noflush". Otherwise, the value is FALSE (see <code>stty(1)</code>).
<code>autosynch</code>	If <code>autosynch</code> and <code>localchars</code> are both TRUE, then when either the <code>interrupt</code> or <code>quit</code> characters are typed (see <code>set</code> for descriptions of <code>interrupt</code> and <code>quit</code>), the resulting TELNET sequence sent is followed by the TELNET SYNCH sequence. This procedure <i>should</i> cause the remote system to begin throwing away all previously typed input until both of the TELNET sequences have been read and acted upon. The initial value of this toggle is FALSE.
<code>binary</code>	Enable or disable the TELNET BINARY option on both input and output.
<code>inbinary</code>	Enable or disable the TELNET BINARY option on input.
<code>outbinary</code>	Enable or disable the TELNET BINARY option on output.
<code>crlf</code>	Determines how carriage returns are sent. If the value is TRUE, then carriage returns will be sent as <CR><LF>. If the value is FALSE, then carriage returns will be sent as <CR><NUL>. The initial value for this toggle is FALSE.
<code>crmod</code>	Toggle RETURN mode. When this mode is enabled, most RETURN characters received from the remote host will be mapped into a RETURN followed by a line feed. This mode does not affect those characters typed by the user, only those received from the remote host. This mode is useful only for remote hosts that send RETURN but never send LINEFEED. The initial value for this toggle is FALSE.
<code>debug</code>	Toggle socket level debugging (only available to the super-user). The initial value for this toggle is FALSE.
<code>localchars</code>	If this toggle is TRUE, then the <code>flush</code> , <code>interrupt</code> , <code>quit</code> , <code>erase</code> , and <code>kill</code> characters (see <code>set</code>) are recognized locally, and transformed into appropriate TELNET control sequences, respectively <code>ao</code> , <code>ip</code> , <code>brk</code> , <code>ec</code> , and <code>e1</code> (see <code>send</code>). The initial value for this toggle is TRUE in "line by line" mode, and FALSE in "character at a time" mode. When the LINEMODE option is enabled, the value of <code>localchars</code> is ignored, and assumed always to be TRUE. If LINEMODE has ever been enabled, then <code>quit</code> is sent as <code>abort</code> , and <code>eof</code> and <code>suspend</code> are sent as <code>eof</code> and <code>susp</code> (see <code>send</code> above).
<code>netdata</code>	Toggle the display of all network data (in hexadecimal format). The initial value for this toggle is FALSE.
<code>options</code>	Toggle the display of some internal TELNET protocol processing (having to do with <code>telnet</code> options). The initial value for this toggle is FALSE.

prettydump	When the netdata toggle is enabled, if prettydump is enabled, the output from the netdata command will be formatted in a more user readable format. Spaces are put between each character in the output. The beginning of any TELNET escape sequence is preceded by an asterisk (*) to aid in locating them.
skiprc	When the skiprc toggle is TRUE, TELNET skips the reading of the .telnetrc file in the user's home directory when connections are opened. The initial value for this toggle is FALSE.
termdata	Toggles the display of all terminal data (in hexadecimal format). The initial value for this toggle is FALSE.
?	Display the legal toggle commands.

environ *argument* . . .

The environ command is used to manipulate variables that may be sent through the TELNET ENVIRON option. The initial set of variables is taken from the users environment. Only the DISPLAY and PRINTER variables are exported by default. Valid arguments for the environ command are:

define <i>variable value</i>	Define <i>variable</i> to have a value of <i>value</i> . Any variables defined by this command are automatically exported. The <i>value</i> may be enclosed in single or double quotes, so that tabs and spaces may be included.
undefine <i>variable</i>	Remove <i>variable</i> from the list of environment variables.
export <i>variable</i>	Mark the <i>variable</i> to be exported to the remote side.
unexport <i>variable</i>	Mark the <i>variable</i> to not be exported unless explicitly requested by the remote side.
list	List the current set of environment variables. Those marked with an asterisk (*) will be sent automatically. Other variables will be sent only if explicitly requested.
?	Prints out help information for the environ command.

logout

Sends the telnet logout option to the remote side. This command is similar to a close command. However, if the remote side does not support the logout option, nothing happens. If, however, the remote side does support the logout option, this command should cause the remote side to close the TELNET connection. If the remote side also supports the concept of suspending a user's session for later reattachment, the logout argument indicates that the remote side should

telnet(1)

terminate the session immediately.

FILES \$HOME/.telnetrc
file that contains commands to be executed before initiating a telnet session

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtnetc

SEE ALSO rlogin(1), sh(1), stty(1), hosts(4), ipnodes(4), nologin(4), telnetrc(4), attributes(5), inet(7P), inet6(7P)

DIAGNOSTICS NO LOGINS: System going down in *N* minutes
The machine is in the process of being shut down and logins have been disabled.

NOTES On some remote systems, echo has to be turned off manually when in "line by line" mode.

In "old line by line" mode, or LINEMODE, the terminal's EOF character is only recognized (and sent to the remote system) when it is the first character on a line.

NAME	test – evaluate condition(s)
SYNOPSIS	<pre>/usr/bin/test [condition] [[condition]]</pre>
sh	<pre>test [condition] [[condition]]</pre>
csh	<pre>test [condition] [[condition]]</pre>
ksh	<pre>test [condition] [[condition]]</pre>
DESCRIPTION	<p>The <code>test</code> utility evaluates the <i>condition</i> and indicates the result of the evaluation by its exit status. An exit status of zero indicates that the condition evaluated as true and an exit status of 1 indicates that the condition evaluated as false.</p> <p>In the first form of the utility shown using the SYNOPSIS:</p> <pre>test [condition]</pre> <p>the square brackets denote that <i>condition</i> is an optional operand and are not to be entered on the command line.</p> <p>In the second form of the utility shown using the SYNOPSIS:</p> <pre>[[condition]]</pre> <p>the first open square bracket, [, is the required utility name. <i>condition</i> is optional, as denoted by the inner pair of square brackets. The final close square bracket,], is a required operand.</p> <p>See <code>largefile(5)</code> for the description of the behavior of <code>test</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).</p> <p>The <code>test</code> and [utilities evaluate the condition <i>condition</i> and, if its value is true, set exit status to 0. Otherwise, a non-zero (false) exit status is set. <code>test</code> and [also set a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.</p> <p>All operators, flags, and brackets (brackets used as shown in the last SYNOPSIS line) must be separate arguments to these commands. Normally these arguments are separated by spaces.</p>
OPERANDS	<p>The primaries listed below with two elements of the form:</p> <pre>-primary_operator primary_operand</pre> <p>are known as <i>unary primaries</i>. The primaries with three elements in either of the two forms:</p>

test(1)

```
primary_operand -primary_operator primary_operand  
primary_operand primary_operator primary_operand
```

are known as *binary primaries*.

If any file operands except for `-h` and `-L` primaries refer to symbolic links, the symbolic link is expanded and the test is performed on the resulting file.

If you test a file you own (the `-r` `-w` or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission.

The `=` and `!=` primaries have a higher precedence than the unary primaries. The `=` and `!=` primaries always expect arguments; therefore, `=` and `!=` cannot be used as an argument to the unary primaries.

The following primaries can be used to construct *condition*:

<code>-a file</code>	True if <i>file</i> exists. (Not available in sh.)
<code>-b file</code>	True if <i>file</i> exists and is a block special file.
<code>-c file</code>	True if <i>file</i> exists and is a character special file.
<code>-d file</code>	True if <i>file</i> exists and is a directory.
<code>-e file</code>	True if <i>file</i> exists. (Not available in sh.)
<code>-f file</code>	True if <i>file</i> exists and is a regular file. Alternatively, if <code>/usr/bin/sh</code> users specify <code>/usr/ucb</code> before <code>/usr/bin</code> in their <code>PATH</code> environment variable, then <code>test</code> will return true if <i>file</i> exists and is (<code>not-a-directory</code>). The <code>csh</code> <code>test</code> and <code>[</code> built-ins always use this alternative behavior.
<code>-g file</code>	True if <i>file</i> exists and its set group ID flag is set.
<code>-G file</code>	True if <i>file</i> exists and its group matches the effective group ID of this process. (Not available in sh.)
<code>-h file</code>	True if <i>file</i> exists and is a symbolic link.
<code>-k file</code>	True if <i>file</i> exists and has its sticky bit set.
<code>-L file</code>	True if <i>file</i> exists and is a symbolic link.
<code>-n string</code>	True if the length of <i>string</i> is non-zero.
<code>-o option</code>	True if option named <i>option</i> is on. (Not available in <code>csh</code> or <code>sh</code> .)
<code>-O file</code>	True if <i>file</i> exists and is owned by the effective user ID of this process. (Not available in sh.)
<code>-p file</code>	True if <i>file</i> is a named pipe (FIFO).

<code>-r file</code>	True if <i>file</i> exists and is readable.
<code>-s file</code>	True if <i>file</i> exists and has a size greater than zero.
<code>-S file</code>	True if <i>file</i> exists and is a socket. (Not available in sh.)
<code>-t [file_descriptor]</code>	True if the file whose file descriptor number is <i>file_descriptor</i> is open and is associated with a terminal. If <i>file_descriptor</i> is not specified, 1 is used as a default value.
<code>-u file</code>	True if <i>file</i> exists and its set-user-ID flag is set.
<code>-w file</code>	True if <i>file</i> exists and is writable. True will indicate only that the write flag is on. The <i>file</i> will not be writable on a read-only file system even if this test indicates true.
<code>-x file</code>	True if <i>file</i> exists and is executable. True will indicate only that the execute flag is on. If <i>file</i> is a directory, true indicates that <i>file</i> can be searched.
<code>-z string</code>	True if the length of string <i>string</i> is zero.
<code>file1 -nt file2</code>	True if <i>file1</i> exists and is newer than <i>file2</i> . (Not available in sh.)
<code>file1 -ot file2</code>	True if <i>file1</i> exists and is older than <i>file2</i> . (Not available in sh.)
<code>file1 -ef file2</code>	True if <i>file1</i> and <i>file2</i> exist and refer to the same file. (Not available in sh.)
<code>string</code>	True if the string <i>string</i> is not the null string.
<code>string1 = string2</code>	True if the strings <i>string1</i> and <i>string2</i> are identical.
<code>string1 != string2</code>	True if the strings <i>string1</i> and <i>string2</i> are not identical.
<code>n1 -eq n2</code>	True if the integers <i>n1</i> and <i>n2</i> are algebraically equal.
<code>n1 -ne n2</code>	True if the integers <i>n1</i> and <i>n2</i> are not algebraically equal.
<code>n1 -gt n2</code>	True if the integer <i>n1</i> is algebraically greater than the integer <i>n2</i> .
<code>n1 -ge n2</code>	True if the integer <i>n1</i> is algebraically greater than or equal to the integer <i>n2</i> .
<code>n1 -lt n2</code>	True if the integer <i>n1</i> is algebraically less than the integer <i>n2</i> .
<code>n1 -le n2</code>	True if the integer <i>n1</i> is algebraically less than or equal to the integer <i>n2</i> .

test(1)

condition1 -a *condition2* True if both *condition1* and *condition2* are true. The -a binary primary is left associative and has higher precedence than the -o binary primary.

condition1 -o *condition2* True if either *condition1* or *condition2* is true. The -o binary primary is left associative.

These primaries can be combined with the following operators:

! *condition* True if *condition* is false.

(*condition*) True if *condition* is true. The parentheses () can be used to alter the normal precedence and associativity. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

The algorithm for determining the precedence of the operators and the return value that will be generated is based on the number of arguments presented to `test`. (However, when using the [. . .] form, the right-bracket final argument will not be counted in this algorithm.)

In the following list, \$1, \$2, \$3 and \$4 represent the arguments presented to `test` as a *condition*, *condition1*, or *condition2*.

0 arguments: Exit false (1).

1 argument: Exit true (0) if \$1 is not null. Otherwise, exit false.

2 arguments:

- If \$1 is !, exit true if \$2 is null, false if \$2 is not null.
- If \$1 is a unary primary, exit true if the unary test is true, false if the unary test is false.
- Otherwise, produce unspecified results.

3 arguments:

- If \$2 is a binary primary, perform the binary test of \$1 and \$3.
- If \$1 is !, negate the two-argument test of \$2 and \$3.
- Otherwise, produce unspecified results.

4 arguments:

- If \$1 is !, negate the three-argument test of \$2, \$3, and \$4.
- Otherwise, the results are unspecified.

USAGE Scripts should be careful when dealing with user-supplied input that could be confused with primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like `test "$1" -a "$2"` should be written as `test "$1" && test "$2"` to avoid problems if a user supplied values such as \$1 set to ! and \$2 set to the null string. That is, in cases where maximal

portability is of concern, replace `test expr1 -a expr2` with `test expr1 && test expr2`, and replace `test expr1 -o expr2` with `test expr1 || test expr2`. But notice that, in `test`, `-a` has *higher* precedence than `-o`, while `&&` and `||` have *equal* precedence in the shell.

Parentheses or braces can be used in the shell command language to effect grouping.

Parentheses must be escaped when using `sh`. For example:

```
test \( expr1 -a expr2 \) -o expr3
```

This command is not always portable outside XSI-conformant systems. The following form can be used instead:

```
( test expr1 && test expr2 ) || test expr3
```

The two commands:

```
test "$1"
test ! "$1"
```

could not be used reliably on some historical systems. Unexpected results would occur if such a *string* condition were used and `$1` expanded to `!`, `(`, or a known unary primary. Better constructs are, respectively,

```
test -n "$1"
test -z "$1"
```

Historical systems have also been unreliable given the common construct:

```
test "$response" = "expected string"
```

One of the following is a more reliable form:

```
test "X$response" = "Xexpected string"
test "expected string" = "$response"
```

Notice that the second form assumes that `expected string` could not be confused with any unary primary. If `expected string` starts with `-`, `(`, `!` or even `=`, the first form should be used instead. Using the preceding rules without the marked extensions, any of the three comparison forms is reliable, given any input. (However, observe that the strings are quoted in all cases.)

Because the string comparison binary primaries, `=` and `!=`, have a higher precedence than any unary primary in the `>4` argument case, unexpected results can occur if arguments are not properly prepared. For example, in

```
test -d $1 -o -d $2
```

If `$1` evaluates to a possible directory name of `=`, the first three arguments are considered a string comparison, which causes a syntax error when the second `-d` is encountered. One of the following forms prevents this; the second is preferred:

test(1)

```
test \( -d "$1" \) -o \( -d "$2" \)
test -d "$1" || test -d "$2"
```

Also in the >4 argument case:

```
test "$1" = "bat" -a "$2" = "ball"
```

Syntax errors will occur if \$1 evaluates to (or !. One of the following forms prevents this; the third is preferred:

```
test "X$1" = "Xbat" -a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

EXAMPLES

In the `if` command examples, three conditions are tested, and if all three evaluate as true or successful, then their validities are written to the screen. The three tests are:

- if a variable set to 1 is greater than 0,
- if a variable set to 2 is equal to 2, and
- if the word "root" is included in the text file `/etc/passwd`.

`/usr/bin/test`

EXAMPLE 1 Using `/usr/bin/test`

Perform a `mkdir` if a directory does not exist:

```
test ! -d tempdir && mkdir tempdir
```

Wait for a file to become non-readable:

```
while test -r thefile
do
    sleep 30
done
echo "thefile" is no longer readable'
```

Perform a command if the argument is one of three strings (two variations), using the open bracket version `[` of the `test` command:

```
if [ "$1" = "pear" ] || [ "$1" = "grape" ] || [ "$1" = "apple" ]
then
    command
fi
case "$1" in
    pear|grape|apple) command;;
esac
```

The test built-in

The two forms of the `test` built-in follow the Bourne shell's `if` example.

EXAMPLE 2 Using the `sh` built-in

```
ZERO=0 ONE=1 TWO=2 ROOT=root
```

```
if [ $ONE -gt $ZERO ]
```

EXAMPLE 2 Using the sh built-in *(Continued)*

```
[ $TWO -eq 2 ]
grep $ROOT /etc/passwd >&1 > /dev/null # discard output
then
    echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
        "a user-name in the password file"
else
    echo "At least one of the three test conditions is false"
fi
```

EXAMPLE 3 Using the test built-in

Examples of the test built-in:

```
test `grep $ROOT /etc/passwd >&1 /dev/null` # discard output
echo $? # test for success
[ `grep nosuchname /etc/passwd >&1 /dev/null` ]
echo $? # test for failure
```

cs **EXAMPLE 4** Using the csh built-in

```
@ ZERO = 0; @ ONE = 1; @ TWO = 2; set ROOT = root
grep $ROOT /etc/passwd >&1 /dev/null # discard output
# $status must be tested for immediately following grep
if ( "$status" == "0" && $ONE > $ZERO && $TWO == 2 ) then
    echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
        "a user-name in the password file"
endif
```

ksh **EXAMPLE 5** Using the ksh built-in

```
ZERO=0 ONE=1 TWO=$((ONE+ONE)) ROOT=root
if ((ONE > ZERO)) # arithmetical comparison
[[ $TWO = 2 ]] # string comparison
[ `grep $ROOT /etc/passwd >&1 /dev/null` ] # discard output
then
    echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
        "a user-name in the password file"
else
    echo "At least one of the three test conditions is false"
fi
```

test(1)

Using -e option in sh

EXAMPLE 6 Using /usr/bin/test for the -e option

If one really wants to use the -e option in sh, use /usr/bin/test, as in the following:

```
if [ ! -h $PKG_INSTALL_ROOT$rLink ] && /usr/bin/test -e
$PKG_INSTALL_ROOT/usr/bin/$rFile ; then
    ln -s $rFile $PKG_INSTALL_ROOT$rLink
fi
```

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of test: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

- 0 *condition* evaluated to true.
- 1 *condition* evaluated to false or *condition* was missing.
- >1 An error occurred.

ATTRIBUTES

NOTES

The not-a-directory alternative to the -f option is a transition aid for BSD applications and may not be supported in future releases.

NAME	test – condition evaluation command
SYNOPSIS	<code>/usr/ucb/test</code> <i>expression</i> <i>expression</i>
DESCRIPTION	<p><code>test</code> evaluates the expression <i>expression</i> and, if its value is true, sets 0 (true) exit status; otherwise, a non-zero (false) exit status is set. <code>test</code> also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.</p> <p>All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line) must be separate arguments to the <code>test</code> command; normally these items are separated by spaces.</p>
Primitives	<p>The following primitives are used to construct <i>expression</i>:</p> <ul style="list-style-type: none"> <code>-r filename</code> True if <i>filename</i> exists and is readable. <code>-w filename</code> True if <i>filename</i> exists and is writable. <code>-x filename</code> True if <i>filename</i> exists and is executable. <code>-f filename</code> True if <i>filename</i> exists and is a regular file. Alternatively, if <code>/usr/bin/sh</code> users specify <code>/usr/ucb</code> before <code>/usr/bin</code> in their <code>PATH</code> environment variable, then <code>test</code> will return true if <i>filename</i> exists and is (<code>not-a-directory</code>). This is also the default for <code>/usr/bin/csh</code> users. <code>-d filename</code> True if <i>filename</i> exists and is a directory. <code>-c filename</code> True if <i>filename</i> exists and is a character special file. <code>-b filename</code> True if <i>filename</i> exists and is a block special file. <code>-p filename</code> True if <i>filename</i> exists and is a named pipe (fifo). <code>-u filename</code> True if <i>filename</i> exists and its set-user- ID bit is set. <code>-g filename</code> True if <i>filename</i> exists and its set-group- ID bit is set. <code>-k filename</code> True if <i>filename</i> exists and its sticky bit is set. <code>-s filename</code> True if <i>filename</i> exists and has a size greater than zero. <code>-t[<i>fildev</i>]</code> True if the open file whose file descriptor number is <i>fildev</i> (1 by default) is associated with a terminal device. <code>-z s1</code> True if the length of string <i>s1</i> is zero. <code>-n s1</code> True if the length of the string <i>s1</i> is non-zero. <code>s1 = s2</code> True if strings <i>s1</i> and <i>s2</i> are identical. <code>s1 != s2</code> True if strings <i>s1</i> and <i>s2</i> are <i>not</i> identical. <code>s1</code> True if <i>s1</i> is <i>not</i> the null string.

test(1B)

n1 -eq *n2* True if the integers *n1* and *n2* are algebraically equal. Any of the comparisons -ne, -gt, -ge, -lt, and -le may be used in place of -eq.

Operators These primaries may be combined with the following operators:

! Unary negation operator.
-a Binary *and* operator.
-o Binary *or* operator (-a has higher precedence than -o).
(*expression*) Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO find(1), sh(1), attributes(5)

NOTES The not-a-directory alternative to the -f option is a transition aid for BSD applications and may not be supported in future releases.

If you test a file you own (the -r , -w , or -x tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission. The correct exit status will be set if you are super-user.

The = and != operators have a higher precedence than the -r through -n operators, and = and != always expect arguments; therefore, = and != cannot be used with the -r through -n operators.

If more than one argument follows the -r through -n operators, only the first argument is examined; the others are ignored, unless a -a or a -o is the second argument.

NAME	test – condition evaluation command
SYNOPSIS	test <i>expression</i> <i>expression</i>
DESCRIPTION	<p>test evaluates the expression <i>expression</i> and if its value is true, sets a 0 (TRUE) exit status; otherwise, a non-zero (FALSE) exit status is set; test also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.</p> <p>All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line) must be separate arguments to test. Normally these items are separated by spaces.</p>
Primitives	<p>The following primitives are used to construct <i>expression</i>:</p> <ul style="list-style-type: none"> -r <i>filename</i> True if <i>filename</i> exists and is readable. -w <i>filename</i> True if <i>filename</i> exists and is writable. -x <i>filename</i> True if <i>filename</i> exists and is executable. -f <i>filename</i> True if <i>filename</i> exists and is a regular file. -d <i>filename</i> True if <i>filename</i> exists and is a directory. -c <i>filename</i> True if <i>filename</i> exists and is a character special file. -b <i>filename</i> True if <i>filename</i> exists and is a block special file. -p <i>filename</i> True if <i>filename</i> exists and is a named pipe (FIFO). -u <i>filename</i> True if <i>filename</i> exists and its set-user-ID bit is set. -g <i>filename</i> True if <i>filename</i> exists and its set-group-ID bit is set. -k <i>filename</i> True if <i>filename</i> exists and its sticky bit is set. -s <i>filename</i> True if <i>filename</i> exists and has a size greater than 0. -t[<i>fildev</i>] True if the open file whose file descriptor number is <i>fildev</i> (1 by default) is associated with a terminal device. -z <i>s1</i> True if the length of string <i>s1</i> is 0. -n <i>s1</i> True if the length of the string <i>s1</i> is non-zero.

test(1F)

`s1 = s2` True if strings `s1` and `s2` are identical.
`s1 != s2` True if strings `s1` and `s2` are *not* identical.
`s1` True if `s1` is *not* the null string.
`n1 -eq n2` True if the integers `n1` and `n2` are algebraically equal. Any of the comparisons `-ne`, `-gt`, `-ge`, `-lt`, and `-le` may be used in place of `-eq`.

Operators These primaries may be combined with the following operators:

`!`
Unary negation operator.
`-a`
Binary *and* operator.
`-o`
Binary *or* operator (`-a` has higher precedence than `-o`).
'(*expression*)'
Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `find(1)`, `sh(1)`, `attributes(5)`

NOTES If you test a file you own (the `-r`, `-w`, or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission. The correct exit status will be set if you are super-user.

The `=` and `!=` operators have a higher precedence than the `-r` through `-n` operators, and `=` and `!=` always expect arguments; therefore, `=` and `!=` cannot be used with the `-r` through `-n` operators.

If more than one argument follows the `-r` through `-n` operators, only the first argument is examined; the others are ignored, unless a `-a` or a `-o` is the second argument.

NAME	tftp – trivial file transfer program
SYNOPSIS	tftp [<i>host</i> [<i>port</i>]]
DESCRIPTION	tftp is the user interface to the Internet TFTP (Trivial File Transfer Protocol), which allows users to transfer files to and from a remote machine. The remote <i>host</i> and optional <i>port</i> may be specified on the command line, in which case tftp uses <i>host</i> as the default host, and if specified, <i>port</i> as the default port, for future transfers. See the connect command below.
USAGE	Once tftp is running, it issues the prompt tftp> and recognizes the following commands:
Commands	<p>connect <i>host-name</i> [<i>port</i>]</p> <p>Set the <i>host</i>, and optionally <i>port</i>, for transfers. The TFTP protocol, unlike the FTP protocol, does not maintain connections between transfers; thus, the connect command does not actually create a connection, but merely remembers what host is to be used for transfers. You do not have to use the connect command; the remote host can be specified as part of the get or put commands.</p> <p>mode <i>transfer-mode</i></p> <p>Set the mode for transfers; <i>transfer-mode</i> may be one of <i>ascii</i> or <i>binary</i>. The default is <i>ascii</i>.</p> <p>put <i>filename</i></p> <p>put <i>localfile remotefile</i></p> <p>put <i>filename1 filename2 . . . filenameN remote-directory</i></p> <p>Transfer a file, or a set of files, to the specified remote file or directory. The destination can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:</p> <p><i>host :filename</i></p> <p>to specify both a <i>host</i> and <i>filename</i> at the same time. If the latter form is used, the specified host becomes the default for future transfers. If the remote-directory form is used, the remote host is assumed to be running the UNIX system.</p> <p>The <i>host</i> can be a host name (see <i>hosts(4)</i> or <i>ipnodes(4)</i>) or an IPv4 or IPv6 address string (see <i>inet(7P)</i> or <i>inet6(7P)</i>). Since IPv6 addresses already contain ":"s, the <i>host</i> should be enclosed in square brackets when an IPv6 address is used. Otherwise, the first occurrence of a colon will be interpreted as the separator between the <i>host</i> and the <i>filename</i>. For example,</p> <p>[1080::8:800:200c:417A]:myfile</p> <p>Files may be written only if they already exist and are publicly writable. See <i>in.tftpd(1M)</i>.</p> <p>get <i>filename</i></p> <p>get <i>remotename localname</i></p> <p>get <i>filename1 filename2 filename3 . . . filenameN</i></p>

tftp(1)

Get a file or set of files (three or more) from the specified remote *sources*. *source* can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:

host:filename

to specify both a host and filename at the same time. If the latter form is used, the last host specified becomes the default for future transfers. See the `put` command regarding specifying a *host*.

`quit`

Exit `tftp`. An EOF also exits.

`verbose`

Toggle verbose mode.

`trace`

Toggle packet tracing.

`status`

Show current status.

`rexmt` *retransmission-timeout*

Set the per-packet retransmission timeout, in seconds.

`timeout` *total-transmission-timeout*

Set the total transmission timeout, in seconds.

`ascii`

Shorthand for mode `ascii`.

`binary`

Shorthand for mode `binary`.

`blksize` *transfer-blocksize*

The value of the transfer blocksize option to negotiate with the server. A value of 0 disables the negotiation of this option.

`srexmt` *server-retransmission-timeout*

The value of the retransmission timeout option to request that the server uses. A value of 0 disables the negotiation of this option.

`tsize`

A toggle that sends the transfer size option to the server. By default, the option is not sent. The transfer size option is not sent with a `write` request when the *transfer-mode* is `ascii`.

? [*command-name* ...]

Print help information.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtftp

SEE ALSO `in.tftpd(1M)`, `hosts(4)`, `ipnodes(4)`, `attributes(5)`, `inet(7P)`, `inet6(7P)`

Malkin, G. and Harkin, A. *RFC 2347, TFTP Option Extension*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2348, TFTP Blocksize Option*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2349, TFTP Timeout Interval and Transfer Size Options*. The Internet Society. May 1998

Sollins, K.R. *RFC 1350, The TFTP Protocol (Revision 2)*. Network Working Group. July 1992.

NOTES The default *transfer-mode* is `ascii`. This differs from pre-SunOS 4.0 and pre-4.3BSD systems, so explicit action must be taken when transferring non-ASCII binary files such as executable commands.

Because there is no user-login or validation within the TFTP protocol, many remote sites restrict file access in various ways. Approved methods for file access are specific to each site, and therefore cannot be documented here.

When using the `get` command to transfer multiple files from a remote host, three or more files must be specified. If two files are specified, the second file is used as a local file.

time(1)

NAME	time – time a simple command
SYNOPSIS	time [-p] <i>utility</i> [<i>argument...</i>]
DESCRIPTION	<p>The <code>time</code> utility invokes <i>utility</i> operand with <i>argument</i>, and writes a message to standard error that lists timing statistics for <i>utility</i>. The message includes the following information:</p> <ul style="list-style-type: none">■ The elapsed (real) time between invocation of <i>utility</i> and its termination.■ The User CPU time, equivalent to the sum of the <code>tms_utime</code> and <code>tms_cutime</code> fields returned by the <code>times(2)</code> function for the process in which <i>utility</i> is executed.■ The System CPU time, equivalent to the sum of the <code>tms_stime</code> and <code>tms_cstime</code> fields returned by the <code>times()</code> function for the process in which <i>utility</i> is executed. <p>When <code>time</code> is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities <code>a</code> and <code>c</code>, respectively:</p> <pre>time a b c { time a } b c a b time c a b (time c)</pre>
OPTIONS	<p>The following option is supported:</p> <p><code>-p</code> Writes the timing output to standard error in the following format:</p> <pre>real %f\nuser %f\nsys %f\n < real seconds>, <user seconds>, <system seconds></pre>
OPERANDS	<p>The following operands are supported:</p> <p><i>utility</i> The name of the utility that is to be invoked.</p> <p><i>argument</i> Any string to be supplied as an argument when invoking <i>utility</i>.</p>
USAGE	<p>The <code>time</code> utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings. Most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.</p>
EXAMPLES	<p>EXAMPLE 1 Using the time command</p> <p>It is frequently desirable to apply <code>time</code> to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file. This single file can then be invoked as a utility, and the <code>time</code> applies to everything in the file.</p> <p>Alternatively, the following command can be used to apply <code>time</code> to a complex command:</p>

EXAMPLE 1 Using the time command (Continued)

```
example% time sh -c 'complex-command-line'
```

EXAMPLE 2 Using time in the csh shell

The following two examples show the differences between the csh version of `time` and the version in `/usr/bin/time`. These examples assume that `csh` is the shell in use.

```
example% time find / -name csh.1 -print
/usr/share/man/man1/csh.1
95.0u 692.0s 1:17:52 16% 0+0k 0+0io 0pf+0w
```

See `csh(1)` for an explanation of the format of `time` output.

```
example% /usr/bin/time find / -name csh.1 -print
/usr/share/man/man1/csh.1
real  1:23:31.5
user   1:33.2
sys    11:28.2
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `time`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, `NLSPATH`, and `PATH`.

EXIT STATUS

If `utility` is invoked, the exit status of `time` will be the exit status of `utility`. Otherwise, the `time` utility will exit with one of the following values:

1-125	An error occurred in the <code>time</code> utility.
126	<code>utility</code> was found but could not be invoked.
127	<code>utility</code> could not be found.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

SEE ALSO

`csh(1)`, `shell_builtins(1)`, `timex(1)`, `times(2)`, `attributes(5)`, `environ(5)`, `standards(5)`

NOTES

When the `time` command is run on a multiprocessor machine, the total of the values printed for `user` and `sys` can exceed `real`. This is because on a multiprocessor machine it is possible to divide the task between the various processors.

time(1)

When the command being timed is interrupted, the timing values displayed may not always be accurate.

BUGS Elapsed time is accurate to the second, while the CPU times are measured to the 100th second. Thus the sum of the CPU times can be up to a second larger than the elapsed time.

NAME times – shell built-in function to report time usages of the current shell

sh **times**

ksh **times**

sh Print the accumulated user and system times for processes run from the shell.

ksh Print the accumulated user and system times for the shell and for processes run from the shell.

On this man page, `ksh(1)` commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `ksh(1)`, `sh(1)`, `time(1)`, `attributes(5)`

timex(1)

NAME	timex – time a command; report process data and system activity
SYNOPSIS	timex [-o] [-p [-fhkmrt]] [-s] <i>command</i>
DESCRIPTION	<p>The given <i>command</i> is executed; the elapsed time, user time and system time spent in execution are reported in seconds. Optionally, process accounting data for the <i>command</i> and all its children can be listed or summarized, and total system activity during the execution interval can be reported.</p> <p>The output of <i>timex</i> is written on standard error.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-o Report the total number of blocks read or written and total characters transferred by <i>command</i> and all its children. This option works only if the process accounting software is installed.-p List process accounting records for <i>command</i> and all its children. This option works only if the process accounting software is installed. Suboptions <i>f</i>, <i>h</i>, <i>k</i>, <i>m</i>, <i>r</i>, and <i>t</i> modify the data items reported. The options are as follows:<ul style="list-style-type: none">-f Print the <i>fork(2)</i>/ <i>exec(2)</i> flag and system exit status columns in the output.-h Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This “hog factor” is computed as (total CPU time)/(elapsed time).-k Instead of memory size, show total kcore-minutes.-m Show mean core size (the default).-r Show CPU factor (user time/(system-time + user-time)).-t Show separate system and user CPU times. The number of blocks read or written and the number of characters transferred are always reported.-s Report total system activity (not just that due to <i>command</i>) that occurred during the execution interval of <i>command</i>. All the data items listed in <i>sar(1)</i> are reported.
EXAMPLES	<p>EXAMPLE 1 Examples of <i>timex</i>.</p> <p>A simple example:</p> <pre>example% timex -ops sleep 60</pre> <p>A terminal session of arbitrary complexity can be measured by timing a sub-shell:</p> <pre>example% timex -opskmt sh session commands EOT</pre>

timex(1)

EXAMPLE 1 Examples of `timex`. (Continued)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

SEE ALSO `sar(1)`, `time(1)`, `exec(2)`, `fork(2)`, `times(2)`, `attributes(5)`

NOTES Process records associated with `command` are selected from the accounting file `/var/adm/pacct` by inference, since process genealogy is not available. Background processes having the same user ID, terminal ID, and execution time window will be spuriously included.

tip(1)

NAME	tip – connect to remote system
SYNOPSIS	tip [-v] [-speed-entry] {hostname phone-number device}
DESCRIPTION	<p>The <code>tip</code> utility establishes a full-duplex terminal connection to a remote host. Once the connection is established, a remote session using <code>tip</code> behaves like an interactive session on a local terminal.</p> <p>The <code>remote</code> file contains entries describing remote systems and line speeds used by <code>tip</code>.</p> <p>Each host has a default baud rate for the connection, or you can specify a speed with the <code>-speed-entry</code> command line argument.</p> <p>When <code>phone-number</code> is specified, <code>tip</code> looks for an entry in the <code>remote</code> file of the form:</p> <pre>tip -speed-entry</pre> <p>When <code>tip</code> finds such an entry, it sets the connection speed accordingly. If it finds no such entry, <code>tip</code> interprets <code>-speed-entry</code> as if it were a system name, resulting in an error message.</p> <p>If you omit <code>-speed-entry</code>, <code>tip</code> uses the <code>tip0</code> entry to set a speed for the connection.</p> <p>When <code>device</code> is specified, <code>tip</code> attempts to open that device, but will do so using the access privileges of the user, rather than <code>tip</code>'s usual access privileges (<code>setuid uucp</code>). The user must have read/write access to the device. The <code>tip</code> utility interprets any character string beginning with the slash character (/) as a device name.</p> <p>When establishing the connection, <code>tip</code> sends a connection message to the remote system. The default value for this message can be found in the <code>remote</code> file.</p> <p>When <code>tip</code> attempts to connect to a remote system, it opens the associated device with an exclusive-open <code>ioctl(2)</code> call. Thus, only one user at a time may access a device. This is to prevent multiple processes from sampling the terminal line. In addition, <code>tip</code> honors the locking protocol used by <code>uucp(1C)</code>.</p> <p>When <code>tip</code> starts up, it reads commands from the file <code>.tiprc</code> in your home directory.</p>
OPTIONS	<code>-v</code> Display commands from the <code>.tiprc</code> file as they are executed.
USAGE	Typed characters are normally transmitted directly to the remote machine, which does the echoing as well.
	At any time that <code>tip</code> prompts for an argument (for example, during setup of a file transfer), the line typed may be edited with the standard erase and kill characters. A null line in response to a prompt, or an interrupt, aborts the dialogue and returns you to the remote machine.
Commands	A tilde (~) appearing as the first character of a line is an escape signal which directs <code>tip</code> to perform some special action. <code>tip</code> recognizes the following escape sequences:

~^D	
~.	Drop the connection and exit (you may still be logged in on the remote machine). <i>Note:</i> If you rlogin and then run <code>tip</code> on the remote host, you must type <code>~~.</code> (tilde tilde dot) to end the <code>tip</code> session. If you type <code>~.</code> (tilde dot), it terminates the rlogin.
~c [<i>name</i>]	Change directory to <i>name</i> . No argument implies change to your home directory.
~!	Escape to an interactive shell on the local machine. Exiting the shell returns you to <code>tip</code> .
~>	Copy file from local to remote.
~<	Copy file from remote to local.
~p <i>from</i> [<i>to</i>]	Send a file to a remote host running the UNIX system. When you use the put command, the remote system runs the command string <code>cat > to</code> while <code>tip</code> sends it the <i>from</i> file. If the <i>to</i> file is not specified, the <i>from</i> file name is used. This command is actually a UNIX-system-specific version of the ' <code>~></code> ' command.
~t <i>from</i> [<i>to</i>]	Take a file from a remote host running the UNIX system. As in the put command the <i>to</i> file defaults to the <i>from</i> file name if it is not specified. The remote host executes the command string <code>cat from ; echo ^A</code> to send the file to <code>tip</code> .
~	Pipe the output from a remote command to a local process. The command string sent to the local system is processed by the shell.
~C	Connect a program to the remote machine. The command string sent to the program is processed by the shell. The program inherits file descriptors 0 as remote line input, 1 as remote line output, and 2 as tty standard error.
~\$	Pipe the output from a local process to the remote host. The command string sent to the local system is processed by the shell.
~#	Send a BREAK to the remote system.
~s	Set a variable (see the discussion below).
~^Z	Stop <code>tip</code> . Only available when run under a shell that supports job control, such as the C shell.
~^Y	Stop only the "local side" of <code>tip</code> . Only available when run under a shell that supports job control, such as the C shell. The "remote side" of <code>tip</code> , that is, the side that displays output from the remote host, is left running.

tip(1)

~? Get a summary of the tilde escapes.

Copying files requires some cooperation on the part of the remote host. When a ~> or ~< escape is used to send a file, tip prompts for a file name (to be transmitted or received) and a command to be sent to the remote system, in case the file is being transferred from the remote system. While tip is transferring a file, the number of lines transferred will be continuously displayed on the screen. A file transfer may be aborted with an interrupt.

Auto-call Units

tip may be used to dial up remote systems using a number of auto-call unit's (ACUs). When the remote system description contains the du capability, tip uses the call-unit (cu), ACU type (at), and phone numbers (pn) supplied. Normally, tip displays verbose messages as it dials.

Depending on the type of auto-dialer being used to establish a connection, the remote host may have garbage characters sent to it upon connection. The user should never assume that the first characters typed to the foreign host are the first ones presented to it. The recommended practice is to immediately type a kill character upon establishing a connection (most UNIX systems either support @ or Control-U as the initial kill character).

tip currently supports the Ventel MD-212+ modem and DC Hayes-compatible modems.

When tip initializes a Hayes-compatible modem for dialing, it sets up the modem to auto-answer. Normally, after the conversation is complete, tip drops DTR, which causes the modem to "hang up."

Most modems can be configured so that when DTR drops, they re-initialize themselves to a preprogrammed state. This can be used to reset the modem and disable auto-answer, if desired.

Additionally, it is possible to start the phone number with a Hayes S command so that you can configure the modem before dialing. For example, to disable auto-answer, set up all the phone numbers in /etc/remote using something like pn=S0=0DT5551212. The S0=0 disables auto-answer.

Remote Host Description

Descriptions of remote hosts are normally located in the system-wide file /etc/remote. However, a user may maintain personal description files (and phone numbers) by defining and exporting the REMOTE shell variable. The remote file must be readable by tip, but a secondary file describing phone numbers may be maintained readable only by the user. This secondary phone number file is /etc/phones, unless the shell variable PHONES is defined and exported. The phone number file contains lines of the form:

system-name phone-number

Each phone number found for a system is tried until either a connection is established, or an end of file is reached. Phone numbers are constructed from '0123456789-=*', where the '=' and '*' are used to indicate a second dial tone should be waited for (ACU dependent).

tip Internal Variables

tip maintains a set of variables which are used in normal operation. Some of these variables are read-only to normal users (root is allowed to change anything of interest). Variables may be displayed and set through the ~s escape. The syntax for variables is patterned after vi(1) and mail(1). Supplying all as an argument to the ~s escape displays all variables that the user can read. Alternatively, the user may request display of a particular variable by attaching a ? to the end. For example, '~s escape?' displays the current escape character.

Variables are numeric (num), string (str), character (char), or Boolean (bool) values. Boolean variables are set merely by specifying their name. They may be reset by prepending a ! to the name. Other variable types are set by appending an = and the value. The entire assignment must not have any blanks in it. A single set command may be used to interrogate as well as set a number of variables.

Variables may be initialized at run time by placing set commands (without the ~s prefix) in a .tiprc file in one's home directory. The -v option makes tip display the sets as they are made. Comments preceded by a # sign can appear in the .tiprc file.

Finally, the variable names must either be completely specified or an abbreviation may be given. The following list details those variables known to tip.

beautify	(bool) Discard unprintable characters when a session is being scripted; abbreviated be. If the nb capability is present, beautify is initially set to off. Otherwise, beautify is initially set to on.
baudrate	(num) The baud rate at which the connection was established; abbreviated ba. If a baud rate was specified on the command line, baudrate is initially set to the specified value. Or, if the br capability is present, baudrate is initially set to the value of that capability. Otherwise, baudrate is set to 300 baud. Once tip has been started, baudrate can only be changed by the super-user.
dialtimeout	(num) When dialing a phone number, the time (in seconds) to wait for a connection to be established; abbreviated dial. dialtimeout is initially set to 60 seconds, and can only be changed by the super-user.
disconnect	(str) The string to send to the remote host to disconnect from it; abbreviated di. If the di capability is present, disconnect is initially set to the value of that capability. Otherwise, disconnect is set to a null string ("").
echocheck	(bool) Synchronize with the remote host during file transfer by waiting for the echo of the last character transmitted; abbreviated

tip(1)

	ec. If the <code>ec</code> capability is present, <code>echocheck</code> is initially set to <code>on</code> . Otherwise, <code>echocheck</code> is initially set to <code>off</code> .
<code>eofread</code>	(str) The set of characters which signify an end-of-transmission during a <code>~<</code> file transfer command; abbreviated <code>eofr</code> . If the <code>ie</code> capability is present, <code>eofread</code> is initially set to the value of that capability. Otherwise, <code>eofread</code> is set to a null string (<code>" "</code>).
<code>eofwrite</code>	(str) The string sent to indicate end-of-transmission during a <code>~></code> file transfer command; abbreviated <code>eofw</code> . If the <code>oe</code> capability is present, <code>eofread</code> is initially set to the value of that capability. Otherwise, <code>eofread</code> is set to a null string (<code>" "</code>).
<code>eol</code>	(str) The set of characters which indicate an end-of-line. <code>tip</code> will recognize escape characters only after an end-of-line. If the <code>e1</code> capability is present, <code>eol</code> is initially set to the value of that capability. Otherwise, <code>eol</code> is set to a null string (<code>" "</code>).
<code>escape</code>	(char) The command prefix (escape) character; abbreviated <code>es</code> . If the <code>es</code> capability is present, <code>escape</code> is initially set to the value of that capability. Otherwise, <code>escape</code> is set to <code>' ~ '</code> .
<code>etimeout</code>	(num) The amount of time, in seconds, that <code>tip</code> should wait for the echo-check response when <code>echocheck</code> is set; abbreviated <code>et</code> . If the <code>et</code> capability is present, <code>etimeout</code> is initially set to the value of that capability. Otherwise, <code>etimeout</code> is set to 10 seconds.
<code>exceptions</code>	(str) The set of characters which should not be discarded due to the beautification switch; abbreviated <code>ex</code> . If the <code>ex</code> capability is present, <code>exceptions</code> is initially set to the value of that capability. Otherwise, <code>exceptions</code> is set to <code>'\t\n\f\b'</code> .
<code>force</code>	(char) The character used to force literal data transmission; abbreviated <code>fo</code> . If the <code>fo</code> capability is present, <code>force</code> is initially set to the value of that capability. Otherwise, <code>force</code> is set to <code>\377</code> (which disables it).
<code>framesize</code>	(num) The amount of data (in bytes) to buffer between file system writes when receiving files; abbreviated <code>fr</code> . If the <code>fs</code> capability is present, <code>framesize</code> is initially set to the value of that capability. Otherwise, <code>framesize</code> is set to 1024.
<code>halfduplex</code>	(bool) Do local echoing because the host is half-duplex; abbreviated <code>hdx</code> . If the <code>hd</code> capability is present, <code>halfduplex</code> is initially set to <code>on</code> . Otherwise, <code>halfduplex</code> is initially set to <code>off</code> .
<code>hardwareflow</code>	(bool) Do hardware flow control; abbreviated <code>hf</code> . If the <code>hf</code> capability is present, <code>hardwareflow</code> is initially set to <code>on</code> . Otherwise, <code>hardwareflowcontrol</code> is initially set to <code>off</code> .

host	(str) The name of the host to which you are connected; abbreviated <code>ho</code> . <code>host</code> is permanently set to the name given on the command line or in the <code>HOST</code> environment variable.
localecho	(bool) A synonym for <code>halfduplex</code> ; abbreviated <code>le</code> .
log	(str) The name of the file to which to log information about outgoing phone calls. <code>log</code> is initially set to <code>/var/adm/aculog</code> , and can only be inspected or changed by the super-user.
parity	(str) The parity to be generated and checked when talking to the remote host; abbreviated <code>par</code> . The possible values are: <code>none</code> > <code>zero</code> Parity is not checked on input, and the parity bit is set to zero on output. <code>one</code> Parity is not checked on input, and the parity bit is set to one on output. <code>even</code> Even parity is checked for on input and generated on output. <code>odd</code> Odd parity is checked for on input and generated on output. If the <code>pa</code> capability is present, <code>parity</code> is initially set to the value of that capability; otherwise, <code>parity</code> is set to <code>none</code> .
phones	The file in which to find hidden phone numbers. If the environment variable <code>PHONES</code> is set, <code>phones</code> is set to the value of <code>PHONES</code> . Otherwise, <code>phones</code> is set to <code>/etc/phones</code> . The value of <code>phones</code> cannot be changed from within <code>tip</code> .
prompt	(char) The character which indicates an end-of-line on the remote host; abbreviated <code>pr</code> . This value is used to synchronize during data transfers. The count of lines transferred during a file transfer command is based on receipt of this character. If the <code>pr</code> capability is present, <code>prompt</code> is initially set to the value of that capability. Otherwise, <code>prompt</code> is set to <code>\n</code> .
raise	(bool) Upper case mapping mode; abbreviated <code>ra</code> . When this mode is enabled, all lower case letters will be mapped to upper case by <code>tip</code> for transmission to the remote machine. If the <code>ra</code> capability is present, <code>raise</code> is initially set to <code>on</code> . Otherwise, <code>raise</code> is initially set to <code>off</code> .
raisechar	(char) The input character used to toggle upper case mapping mode; abbreviated <code>rc</code> . If the <code>rc</code> capability is present, <code>raisechar</code> is initially set to the value of that capability. Otherwise, <code>raisechar</code> is set to <code>\377</code> (which disables it).

tip(1)

<code>rawftp</code>	(bool) Send all characters during file transfers; do not filter non-printable characters, and do not do translations like <code>\n</code> to <code>\r</code> . Abbreviated <code>raw</code> . If the <code>rw</code> capability is present, <code>rawftp</code> is initially set to <code>on</code> . Otherwise, <code>rawftp</code> is initially set to <code>off</code> .
<code>record</code>	(str) The name of the file in which a session script is recorded; abbreviated <code>rec</code> . If the <code>re</code> capability is present, <code>record</code> is initially set to the value of that capability. Otherwise, <code>record</code> is set to <code>tip.record</code> .
<code>remote</code>	The file in which to find descriptions of remote systems. If the environment variable <code>REMOTE</code> is set, <code>remote</code> is set to the value of <code>REMOTE</code> . Otherwise, <code>remote</code> is set to <code>/etc/remote</code> . The value of <code>remote</code> cannot be changed from within <code>tip</code> .
<code>script</code>	(bool) Session scripting mode; abbreviated <code>sc</code> . When <code>script</code> is <code>on</code> , <code>tip</code> will record everything transmitted by the remote machine in the script record file specified in <code>record</code> . If the <code>beautify</code> switch is <code>on</code> , only printable ASCII characters will be included in the script file (those characters between 040 and 0177). The variable <code>exceptions</code> is used to indicate characters which are an exception to the normal beautification rules. If the <code>sc</code> capability is present, <code>script</code> is initially set to <code>on</code> . Otherwise, <code>script</code> is initially set to <code>off</code> .
<code>tabexpand</code>	(bool) Expand TAB characters to SPACE characters during file transfers; abbreviated <code>tab</code> . When <code>tabexpand</code> is <code>on</code> , each tab is expanded to eight SPACE characters. If the <code>tb</code> capability is present, <code>tabexpand</code> is initially set to <code>on</code> . Otherwise, <code>tabexpand</code> is initially set to <code>off</code> .
<code>tandem</code>	(bool) Use <code>XON/XOFF</code> flow control to limit the rate that data is sent by the remote host; abbreviated <code>ta</code> . If the <code>nt</code> capability is present, <code>tandem</code> is initially set to <code>off</code> . Otherwise, <code>tandem</code> is initially set to <code>on</code> .
<code>verbose</code>	(bool) Verbose mode; abbreviated <code>verb</code> ; When verbose mode is enabled, <code>tip</code> prints messages while dialing, shows the current number of lines transferred during a file transfer operations, and more. If the <code>nv</code> capability is present, <code>verbose</code> is initially set to <code>off</code> . Otherwise, <code>verbose</code> is initially set to <code>on</code> .
<code>SHELL</code>	(str) The name of the shell to use for the <code>~!</code> command; default value is <code>/bin/sh</code> , or taken from the environment.
<code>HOME</code>	(str) The home directory to use for the <code>~c</code> command. Default value is taken from the environment.

EXAMPLES

EXAMPLE 1 Using the tip command

An example of the dialog used to transfer files is given below.

EXAMPLE 1 Using the tip command (Continued)

```

arpa% tip monet
[connected]
... (assume we are talking to a UNIX system)...
uchmonet login: sam
Password:
monet% cat sylvester.c
~> Filename: sylvester.c
32 lines transferred in 1 minute 3 seconds
monet%
monet% ~< Filename: reply.c
List command for remote host: cat reply.c
65 lines transferred in 2 minutes
monet%
... (or, equivalently)...
monet% ~p sylvester.c
... (actually echoes as ~[put] sylvester.c)...
32 lines transferred in 1 minute 3 seconds
monet%
monet% ~t reply.c
... (actually echoes as ~[take] reply.c)...
65 lines transferred in 2 minutes
monet%
... (to print a file locally)...
monet% ~|Local command: pr h sylvester.c | lpr
List command for remote host: cat sylvester.c
monet% ~^D
[EOT]
... (back on the local system)...

```

**ENVIRONMENT
VARIABLES**

The following environment variables are read by tip.

REMOTE The location of the remote file.

PHONES The location of the file containing private phone numbers.

HOST A default host to connect to.

HOME One's log-in directory (for chdirs).

SHELL The shell to fork on a '~!' escape.

FILES

/etc/phones

/etc/remote

/var/spool/locks/LCK.*
lock file to avoid conflicts with UUCP

/var/adm/aculog
file in which outgoing calls are logged

~/ .tiprc
initialization file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `cu(1C)`, `mail(1)`, `uucp(1C)`, `vi(1)`, `ioctl(2)`, `attributes(5)`

BUGS There are two additional variables, `chardelay` and `linedelay`, that are currently not implemented.

NAME tnfdump – convert binary TNF file to ASCII

SYNOPSIS **tnfdump** [-r] [-x] *tnf_file...*

DESCRIPTION The **tnfdump** utility converts the specified binary TNF trace files to ASCII. The ASCII output can be used to do performance analysis. The default mode (without the **-r** option) prints all the event records (that were generated by **TNF_PROBE(3TNF)**) and the event descriptor records only. It also orders the events by time.

OPTIONS The following option is supported:

- r** Does a raw conversion of TNF to ASCII. The output is a literal translation of the binary TNF file and includes all the records in the file. This output is useful only if you have a good understanding of TNF. A sample output is listed in **EXAMPLES** below.
- x** Prints all TNF unsigned type argument values in hexadecimal format instead of decimal format.

RETURN VALUES **tnfdump** returns 0 on successful exit.

EXAMPLES **EXAMPLE 1** Converting a file into ASCII

To convert the file `/tmp/trace-2130` into ASCII, use the **tnfdump** command and the name of the binary trace file. Be aware that the **tnfdump** output goes to `stdout` by default.

```
example% tnfdump /tmp/trace-2130
probe tnf_name: "inloop" tnf_string: "keys cookie main loop;\
      file cookie2.c;line 50;sunw%debug in the loop"
probe tnf_name: "end" tnf_string: "keys cookie main end;\
      file cookie2.c;line 41;sunw%debug exiting program"
-----
Elapsed (ms)  Delta (ms)  PID  LWPID  TID  CPU Probe      Data/
              Name      Description . . .
-----

```

tnfdump(1)

EXAMPLE 1 Converting a file into ASCII (Continued)

```
7776.043000      0.009000    8792  1    0 - inloop  loop_count: 4
                                         total_iterations: 9
7776.052000      0.009000    8792  1    0 - inloop  loop_count: 5
                                         total_iterations: 10
7776.061000      0.009000    8792  1    0 - inloop  loop_count: 6
                                         total_iterations: 11
9475.979500  1699.918500    8792  1    0 - end    node_struct:
                                         { type: node_tnf
                                         cur_sum: 9 max_cnt: 12 }
```

All probes that are encountered during execution have a description of it printed out. The description is one per line prefixed by the keyword 'probe'. The name of the probe is in double quotes after the keyword 'tnf_name'. The description of this probe is in double quotes after the keyword 'tnf_string'.

A heading is printed after all the description of the probes are printed. The first column gives the elapsed time in milli-seconds since the first event. The second column gives the elapsed time in milli-seconds since the previous event. The next four columns are the process id, lwp id, thread id, and cpu number. The next column is the name of the probe that generated this event. This can be matched to the probe description explained above. The last column is the data that the event contains, formatted as `arg_name_n` (see `TNF_PROBE(3TNF)`) followed by a colon and the value of that argument. The format of the value depends on its type. `tnf_opaque` arguments are printed in hexadecimal. All other integers are printed in decimal. Strings are printed in double quotes and user-defined records are enclosed in braces '{ }'. The first field of a user defined record indicates its TNF type (see `TNF_DECLARE_RECORD(3TNF)`). The rest of the fields are the members of the record.

A '-' in any column indicates that there is no data for that particular column.

EXAMPLE 2 To do a raw conversion of a file into ASCII

To do a raw conversion of the file `/tmp/trace-4000` into ASCII, use:

```
example% tnfdump -r /tmp/trace-4000
```

The output will look like the following:

```
0x10e00 : {
           tnf_tag 0x109c0    tnf_block_header
           generation 1
           bytes_valid 320
           A_lock 0
           B_lock 0
           next_block 0x0
        }
0x10e10 : {
           tnf_tag 0x10010    probe1
           tnf_tag_arg 0x10e24 <tnf_sched_rec>
           time_delta 128
```

EXAMPLE 2 To do a raw conversion of a file into ASCII (Continued)

```

        test_ulong 4294967295
        test_long -1
    }
0x10e24 : {
        tnfn_tag 0x10cf4    tnfn_sched_rec
            tid 0
            lwpid 1
            pid 13568
            time_base 277077875828500
    }

                4 0x11188   tnf_float32
    }
```

The first number is the file offset of the record. The record is enclosed in braces '{}'. The first column in a record is the slot name (for records whose fields do not have names, it is the type name). The second column in the record is the value of that slot if it is a scalar (only scalars that are of type `tnf_opaque` are printed in hex), or the offset of the record if it is a reference to another record.

The third column in a record is optional. It does not exist for scalar slots of records. If it exists, the third column is a type name with or without angle brackets, or a string in double quotes. Unadorned names indicate a reference to the named metatag record (that is, a reference to a record with that name in the `tnf_name` field). Type names in angled brackets indicate a reference to a record that is an instance of that type (that is, a reference to a record with that name in the `tnf_tag` field). The content of strings are printed out in double quotes at the reference site.

Records that are arrays have their array elements follow the header slots, and are numbered 0, 1, 2, and so on, except strings where the string is written as the 'chars' (pseudo-name) slot.

Records that are events (generated by `TNF_PROBE(3TNF)`) will have a slot name of `tnf_tag_arg` as their second field which is a reference to the schedule record. Schedule records describe more information about the event like the thread-id, process-id, and the `time_base`. The `time_delta` of an event can be added to the `time_base` of the schedule record that the event references, to give an absolute time. This time is expressed as nanoseconds since some arbitrary time in the past (see `gethrtime(3C)`).

EXAMPLE 3 Printing TNF unsigned arguments in hexadecimal

To print TNF unsigned arguments in hexadecimal for the file `/tmp/trace-2192`, use:

```
example% tnfdump -x /tmp/trace-2192
```

The output will look like the following:

```
probe      tnf_name: "start" tnf_string: "keys cookie main;
file test17.c;line 20;sunw%debug starting main"
probe      tnf_name: "inloop" tnf_string: "keys cookie main"
```

EXAMPLE 3 Printing TNF unsigned arguments in hexadecimal (Continued)

```

loop;file test17.c;line 41;sunw%debug in the loop"
probe      tnf_name: "final" tnf_string: "keys cookie main
final;file test17.c;line 32;sunw%debug in the final"

tnfextract(1)

NAME	tnfextract – extract kernel probes output into a trace file
SYNOPSIS	tnfextract [-d <i>dumpfile</i> -n <i>namelist</i>] <i>tnf_file</i>
DESCRIPTION	<p>The <code>tnfextract</code> utility collects kernel trace output from an in-core buffer in the Solaris kernel, or from the memory image of a crashed system, and generates a binary TNF trace file like those produced directly by user programs being traced.</p> <p>Either both or neither of the <code>-d</code> and <code>-n</code> options must be specified. If neither is specified, trace output is extracted from the running kernel. If both are specified, the <code>-d</code> argument names the file containing the (crashed) system memory image, and the <code>-n</code> argument names the file containing the symbol table for the system memory image.</p> <p>The TNF trace file <i>tnf_file</i> produced is exactly the same size as the in-core buffer; it is essentially a snapshot of that buffer. It is legal to run <code>tnfextract</code> while kernel tracing is active, i.e., while the in-core buffer is being written. <code>tnfextract</code> insures that the output file it generates is low-level consistent, i.e., that only whole probes are written out, and that internal data structures in the buffer are not corrupted because the buffer is being concurrently written.</p> <p>The TNF trace file generated is suitable as input to <code>tnfdump(1)</code>, which will generate an ASCII file.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-d <i>dumpfile</i></code> Use <i>dumpfile</i> as the system memory image, instead of the running kernel. The <i>dumpfile</i> is normally the path name of a file generated by the <code>savecore</code> utility.</p> <p><code>-n <i>namelist</i></code> Use <i>namelist</i> as the file containing the symbol table information for the given <i>dumpfile</i>.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>tnf_file</i> output file generated by <code>tnfextract</code> based on kernel trace output from an in-core buffer in the Solaris kernel.</p>
EXAMPLES	<p>EXAMPLE 1 Extracting probes from a running kernel</p> <p>Extract probes from the running kernel into <code>ktrace.out</code>:</p> <pre>example% tnfextract ktrace.out</pre> <p>EXAMPLE 2 Extracting probes from a kernel crash dump</p> <p>Extract probes from a kernel crash dump into <code>ktrace.out</code>:</p> <pre>example% tnfextract -d /var/crash/`uname -n`/vmcore.0 \ -n /var/crash/`uname -n`/unix.0 ktrace.out</pre>
EXIT STATUS	The following exit values are returned:

tnfextract(1)

- 0 Successful completion.
- >0 An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtnfc (32-bit) SUNWtnfcx (64-bit)

touch(1)

NAME	touch, settime – change file access and modification times
SYNOPSIS	touch [-acm] [-r <i>ref_file</i> -t <i>time</i>] <i>file</i> ... touch [-acm] [<i>date_time</i>] <i>file</i> ... settime [-f <i>ref_file</i>] [<i>date_time</i>] <i>file</i> ...
DESCRIPTION	<p>The touch utility sets the access and modification times of each file. The <i>file</i> operand is created if it does not already exist.</p> <p>The time used can be specified by -t <i>time</i>, by the corresponding time fields of the file referenced by -r <i>ref_file</i>, or by the <i>date_time</i> operand. If none of these are specified, touch uses the current time (the value returned by the time(2) function).</p> <p>If neither the -a nor -m options are specified, touch updates both the modification and access times.</p> <p>A user with write access to a file, but who is not the owner of the file or a super-user, can change the modification and access times of that file only to the current time. Attempts to set a specific time with touch will result in an error.</p> <p>The settime utility is equivalent to touch -c [<i>date_time</i>] <i>file</i>.</p>
OPTIONS	The following options are supported in the touch and settime utilities:
touch	The following options are supported for the touch utility:
-a	Changes the access time of <i>file</i> . Does not change the modification time unless -m is also specified.
-c	Does not create a specified <i>file</i> if it does not exist. Does not write any diagnostic messages concerning this condition.
-m	Changes the modification time of <i>file</i> . Does not change the access time unless -a is also specified.
-r <i>ref_file</i>	Uses the corresponding times of the file named by <i>ref_file</i> instead of the current time.
-t <i>time</i>	Uses the specified <i>time</i> instead of the current time. <i>time</i> will be a decimal number of the form: [[CC] YY] MMDDhhmm [.SS]
	where each two digits represent the following:
MM	The month of the year [01-12].
DD	The day of the month [01-31].
hh	The hour of the day [00-23].
mm	The minute of the hour [00-59].
CC	The first two digits of the year.

touch(1)

YY The second two digits of the year.

SS The second of the minute [00-61].

Both CC and YY are optional. If neither is given, the current year will be assumed. If YY is specified, but CC is not, CC will be derived as follows:

If YY is:	CC becomes:
69-99	19
00-38	20
39-68	ERROR

The resulting time will be affected by the value of the TZ environment variable. If the resulting time value precedes the Epoch, touch will exit immediately with an error status. The range of valid times is the Epoch to January 18, 2038.

The range for SS is [00-61] rather than [00-59] because of leap seconds. If SS is 60 or 61, and the resulting time, as affected by the TZ environment variable, does not refer to a leap second, the resulting time will be one or two seconds after a time where SS is 59. If SS is not given, it is assumed to be 0.

settime The following option is supported for the settime utility:

-f *ref_file* Uses the corresponding times of the file named by *ref_file* instead of the current time.

OPERANDS The following operands are supported for the touch and settime utilities:

file A path name of a file whose times are to be modified.

date_time Uses the specified *date_time* instead of the current time. This operand is a decimal number of the form:

MMDDhhmm [YY]

where each two digits represent the following:

MM The month of the year [01-12].

DD The day of the month [01-31].

hh The hour of the day [00-23].

mm The minute of the hour [00-59].

YY The second two digits of the year.

touch(1)

YY is optional. If it is omitted, the current year will be assumed. If YY is specified, the year will be derived as follows:

YY	Corresponding Year
69-99	1969-1999
00-38	2000-2038
39-68	ERROR

If no `-r` option is specified, no `-t` option is specified, at least two operands are specified, and the first operand is an eight- or ten-digit decimal integer, the first operand will be assumed to be a *date_time* operand. Otherwise, the first operand will be assumed to be a *file* operand.

USAGE See `largefile(5)` for the description of the behavior of `touch` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `touch`: `LANG`, `LC_ALL`, `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

TZ Determine the timezone to be used for interpreting the *time* option-argument or the *date_time* operand.

EXIT STATUS The following exit values are returned:

0 The `touch` utility executed successfully and all requested changes were made.

>0 An error occurred. The `touch` utility returned the number of files for which the times could not be successfully modified.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled
Interface Stability	Standard

SEE ALSO `time(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

NOTES Users familiar with the BSD environment will find that for the `touch` utility, the `-f` option is accepted but ignored. The `-f` option is unnecessary because `touch` will succeed for all files owned by the user regardless of the permissions on the files.

touch(1B)

NAME touch – change file access and modification times

SYNOPSIS /usr/ucb/touch [-acfm] file...

DESCRIPTION touch sets the access and modification times of each file to the current time. file is created if it does not already exist.

OPTIONS

- a Change the access time of file. Do not change the modification time unless -m is also specified.
- c Do not create file if it does not exist.
- f Attempt to force the touch in spite of read and write permissions on file.
- m Change the modification time of file. Do not change the access time unless -a is also specified.

USAGE See largefile(5) for the description of the behavior of touch when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

EXIT STATUS The following exit values are returned:

- 0 touch executed successfully and all requested changes were made.
- >0 An error occurred. touch returns the number of files for which the times could not be successfully modified.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

tput(1)

NAME	tput – initialize a terminal or query terminfo database
SYNOPSIS	tput [-T <i>type</i>] <i>capname</i> [<i>parm...</i>] tput -S <<
DESCRIPTION	The tput utility uses the terminfo database to make the values of terminal-dependent capabilities and information available to the shell (see sh(1)); to clear, initialize or reset the terminal; or to return the long name of the requested terminal type. tput outputs a string if the capability attribute (<i>capname</i>) is of type string, or an integer if the attribute is of type integer. If the attribute is of type boolean, tput simply sets the exit status (0 for TRUE if the terminal has the capability, 1 for FALSE if it does not), and produces no output. Before using a value returned on standard output, the user should test the exit status (\$?, see sh(1)) to be sure it is 0. See the EXIT STATUS section.
OPTIONS	The following options are supported: -T <i>type</i> Indicates the <i>type</i> of terminal. Normally this option is unnecessary, because the default is taken from the environment variable TERM. If -T is specified, then the shell variables LINES and COLUMNS and the layer size will not be referenced. -S Allows more than one capability per invocation of tput. The capabilities must be passed to tput from the standard input instead of from the command line (see the example in the EXAMPLES section). Only one <i>capname</i> is allowed per line. The -S option changes the meaning of the 0 and 1 boolean and string exit statuses (see the EXAMPLES section).
OPERANDS	The following operands are supported: <i>capname</i> Indicates the capability attribute from the terminfo database. See terminfo(4) for a complete list of capabilities and the <i>capname</i> associated with each. The following strings will be supported as operands by the implementation in the "C" locale: clear Display the clear-screen sequence. init If the terminfo database is present and an entry for the user's terminal exists (see -T <i>type</i> , above), the following will occur: 1. if present, the terminal's initialization strings will be output (<i>is1</i> , <i>is2</i> , <i>is3</i> , <i>if</i> , <i>iprog</i>), 2. any delays (for instance, newline) specified in the entry will be set in the tty driver,

3. tabs expansion will be turned on or off according to the specification in the entry, and
4. if tabs are not expanded, standard tabs will be set (every 8 spaces). If an entry does not contain the information needed for any of the four above activities, that activity will silently be skipped.

`reset` Instead of putting out initialization strings, the terminal's reset strings will be output if present (`rs1`, `rs2`, `rs3`, `rf`). If the reset strings are not present, but initialization strings are, the initialization strings will be output. Otherwise, `reset` acts identically to `init`.

`longname` If the `terminfo` database is present and an entry for the user's terminal exists (see `-Ttype` above), then the long name of the terminal will be put out. The long name is the last name in the first line of the terminal's description in the `terminfo` database (see `term(5)`).

parm If the attribute is a string that takes parameters, the argument *parm* will be instantiated into the string. An all numeric argument will be passed to the attribute as a number.

EXAMPLES **EXAMPLE 1** Initializing the terminal according to TERM

This example initializes the terminal according to the type of terminal in the environment variable `TERM`. This command should be included in everyone's `.profile` after the environment variable `TERM` has been exported, as illustrated on the `profile(4)` manual page.

```
example% tput init
```

EXAMPLE 2 Resetting a terminal

This example resets an AT&T 5620 terminal, overriding the type of terminal in the environment variable `TERM`:

```
example% tput -T5620 reset
```

EXAMPLE 3 Moving the cursor

The following example sends the sequence to move the cursor to row 0, column 0 (the upper left corner of the screen, usually known as the "home" cursor position).

```
example% tput cup 0 0
```

tput(1)

EXAMPLE 3 Moving the cursor *(Continued)*

This next example sends the sequence to move the cursor to row 23, column 4.

```
example% tput cup 23 4
```

EXAMPLE 4 Echoing the clear-screen sequence

This example echos the clear-screen sequence for the current terminal.

```
example% tput clear
```

EXAMPLE 5 Printing the number of columns

This command prints the number of columns for the current terminal.

```
example% tput cols
```

The following command prints the number of columns for the 450 terminal.

```
example% tput -T450 cols
```

EXAMPLE 6 Setting shell variables

This example sets the shell variables `bold`, to begin stand-out mode sequence, and `offbold`, to end standout mode sequence, for the current terminal. This might be followed by a prompt:

```
echo "${bold}Please type in your name: ${offbold}\c"  
example% bold='tput smso'  
example% offbold='tput rmso'
```

EXAMPLE 7 Setting the exit status

This example sets the exit status to indicate if the current terminal is a hardcopy terminal.

```
example% tput hc
```

EXAMPLE 8 Printing the long name from terminfo

This command prints the long name from the `terminfo` database for the type of terminal specified in the environment variable `TERM`.

```
example% tput longname
```

EXAMPLE 9 Processing several capabilities with one invocation

This example shows `tput` processing several capabilities in one invocation. This example clears the screen, moves the cursor to position 10, 10 and turns on `bold` (extra bright) mode. The list is terminated by an exclamation mark (!) on a line by itself.

```
example% tput -S <<!
> clear
> cup 10 10
> bold
> !
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tput`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

TERM Determine the terminal type. If this variable is unset or null, and if the `-T` option is not specified, an unspecified default terminal type will be used.

EXIT STATUS

The following exit values are returned:

0

- If *capname* is of type boolean and `-S` is not specified, indicates `TRUE`.
- If *capname* is of type string and `-S` is not specified, indicates *capname* is defined for this terminal type.
- If *capname* is of type boolean or string and `-S` is specified, indicates that all lines were successful.
- *capname* is of type integer.
- The requested string was written successfully.

1

- If *capname* is of type boolean and `-S` is not specified, indicates `FALSE`.
- If *capname* is of type string and `-S` is not specified, indicates that *capname* is not defined for this terminal type.

2 Usage error.

3 No information is available about the specified terminal type.

4 The specified operand is invalid.

>4 An error occurred.

-1 *capname* is a numeric variable that is not specified in the `terminfo` database. For instance, `tput -T450 lines` and `tput -T2621 xmc`.

FILES

NAME	tr – translate characters
SYNOPSIS	<pre> /usr/bin/tr [-cs] string1 string2 /usr/bin/tr -s -d [-c] string1 /usr/bin/tr -ds [-c] string1 string2 /usr/xpg4/bin/tr [-cs] string1 string2 /usr/xpg4/bin/tr -s -d [-c] string1 /usr/xpg4/bin/tr -ds [-c] string1 string2 </pre>
DESCRIPTION	<p>The <code>tr</code> utility copies the standard input to the standard output with substitution or deletion of selected characters. The options specified and the <i>string1</i> and <i>string2</i> operands control translations that occur while copying characters and single-character collating elements.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -c Complements the set of characters specified by <i>string1</i>. -d Deletes all occurrences of input characters that are specified by <i>string1</i>. -s Replaces instances of repeated characters with a single character. <p>When the <code>-d</code> option is not specified:</p> <ul style="list-style-type: none"> ■ Each input character found in the array specified by <i>string1</i> is replaced by the character in the same relative position in the array specified by <i>string2</i>. When the array specified by <i>string2</i> is shorter than the one specified by <i>string1</i>, the results are unspecified. ■ If the <code>-c</code> option is specified, the complements of the characters specified by <i>string1</i> (the set of all characters in the current character set, as defined by the current setting of <code>LC_CTYPE</code>, except for those actually specified in the <i>string1</i> operand) are placed in the array in ascending collation sequence, as defined by the current setting of <code>LC_COLLATE</code>. ■ Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously. <p>When the <code>-d</code> option is specified:</p> <ul style="list-style-type: none"> ■ Input characters found in the array specified by <i>string1</i> will be deleted. ■ When the <code>-c</code> option is specified with <code>-d</code>, all characters except those specified by <i>string1</i> will be deleted. The contents of <i>string2</i> will be ignored, unless the <code>-s</code> option is also specified. ■ The same string cannot be used for both the <code>-d</code> and the <code>-s</code> option; when both options are specified, both <i>string1</i> (used for deletion) and <i>string2</i> (used for squeezing) are required.

tr(1)

When the `-s` option is specified, after any deletions or translations have taken place, repeated sequences of the same character will be replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:

```
tr -s '[:space:]'
```

the last operand's array will contain all of the characters in that character class. However, in a case conversion, as described previously, such as

```
tr -s '[:upper:]' '[:lower:]'
```

the last operand's array will contain only those characters defined as the second characters in each of the `toupper` or `tolower` character pairs, as appropriate. (See `toupper(3C)` and `tolower(3C)`).

An empty string used for *string1* or *string2* produces undefined results.

OPERANDS The following operands are supported:

string1

string2 Translation control strings. Each string represents a set of characters to be converted into an array of characters used for the translation.

The operands *string1* and *string2* (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, `tr` will exclude, without a diagnostic, those multi-character elements from the resulting array.

character Any character not described by one of the conventions below represents itself.

`\ octal` Octal sequences can be used to represent characters with specific coded values. An octal sequence consists of a backslash followed by the longest sequence of one-, two-, or three-octal-digit characters (01234567). The sequence causes the character whose encoding is represented by the one-, two- or three-digit octal integer to be placed into the array. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading `\` for each byte.

`\ character` The backslash-escape sequences `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, and `\v` are supported. The results of using any other character, other than an octal digit, following the backslash are unspecified.

<code>/usr/xpg4/bin/tr</code>	<code>c-c</code>	<p>Represents the range of collating elements between the range endpoints, inclusive, as defined by the current setting of the LC_COLLATE locale category. The starting endpoint must precede the second endpoint in the current collation order. The characters or collating elements in the range are placed in the array in ascending collation sequence.</p>
<code>/usr/bin/tr</code>	<code>[c-c]</code>	<p>Represents all characters belonging to the defined character class, as defined by the current setting of the LC_CTYPE locale category. The following character class names will be accepted when specified in <i>string1</i>:</p>
	<code>[:class:]</code>	<pre> alnum blank digit lower punct upper alpha cntrl graph print space xdigit </pre>
		<p>In addition, character class expressions of the form <code>[:name:]</code> are recognized in those locales where the <i>name</i> keyword has been given a <code>charclass</code> definition in the LC_CTYPE category.</p>
		<p><i>Note:</i> <code>/usr/bin/tr</code> supports character class expressions only in singlebyte locales. Use <code>/usr/xpg4/bin/tr</code> to support these expressions in any locale.</p>
		<p>When both the <code>-d</code> and <code>-s</code> options are specified, any of the character class names will be accepted in <i>string2</i>. Otherwise, only character class names <code>lower</code> or <code>upper</code> are valid in <i>string2</i> and then only if the corresponding character class <code>upper</code> and <code>lower</code>, respectively, is specified in the same relative position in <i>string1</i>. Such a specification is interpreted as a request for case conversion. When <code>[:lower:]</code> appears in <i>string1</i> and <code>[:upper:]</code> appears in <i>string2</i>, the arrays will contain the characters from the <code>toupper</code> mapping in the LC_CTYPE category of the current locale. When <code>[:upper:]</code> appears in <i>string1</i> and <code>[:lower:]</code> appears in <i>string2</i>, the arrays will contain the characters from the <code>tolower</code> mapping in the LC_CTYPE category of the current locale. The first character from each mapping pair will be in the array for <i>string1</i> and the second character from each mapping pair will be in the array for <i>string2</i> in the same relative position.</p>
		<p>Except for case conversion, the characters specified by a character class expression are placed in the array in an unspecified order.</p>
		<p>If the name specified for <i>class</i> does not define a valid character class in the current locale, the behavior is undefined.</p>
	<code>[=equiv=]</code>	<p>Represents all characters or collating elements belonging to the same equivalence class as <i>equiv</i>, as defined by the current setting of the LC_COLLATE locale category. An equivalence class expression</p>

tr(1)

	<p>is allowed only in <i>string1</i>, or in <i>string2</i> when it is being used by the combined <code>-d</code> and <code>-s</code> options. The characters belonging to the equivalence class are placed in the array in an unspecified order.</p>
	<p>[<i>x</i>*<i>n</i>] Represents <i>n</i> repeated occurrences of the character <i>x</i>. Because this expression is used to map multiple characters to one, it is only valid when it occurs in <i>string2</i>. If <i>n</i> is omitted or is 0, it is interpreted as large enough to extend the <i>string2</i>-based sequence to the length of the <i>string1</i>-based sequence. If <i>n</i> has a leading 0, it is interpreted as an octal value. Otherwise, it is interpreted as a decimal value.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>tr</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 Creating a list of words</p> <p>The following example creates a list of all words in <i>file1</i>, one per line in <i>file2</i>, where a word is taken to be a maximal string of letters.</p> <pre>tr -cs "[:alpha:]" "[\n*]" <file1 >file2</pre> <p>EXAMPLE 2 Translating characters</p> <p>This example translates all lower-case characters in <i>file1</i> to upper-case and writes the results to standard output.</p> <pre>tr "[:lower:]" "[:upper:]" <file1</pre> <p>Notice that the caveat expressed in the corresponding example in XPG3 is no longer in effect. This case conversion is now a special case that employs the <code>tolower</code> and <code>toupper</code> classifications, ensuring that proper mapping is accomplished (when the locale is correctly defined).</p> <p>EXAMPLE 3 Identifying equivalent characters</p> <p>This example uses an equivalence class to identify accented variants of the base character <i>e</i> in <i>file1</i>, which are stripped of diacritical marks and written to <i>file2</i>.</p> <pre>tr "[=e=" e <file1 >file2</pre>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>tr</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_COLLATE</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	The following exit values are returned: 0 All input was processed successfully. >0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/tr`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Not enabled

`/usr/xpg4/bin/tr`

NOTES Unlike some previous versions, `/usr/xpg4/bin/tr` correctly processes NUL characters in its input stream. NUL characters can be stripped by using `tr -d '\000'`.

tr(1B)

NAME	tr – translate characters				
SYNOPSIS	<code>/usr/ucb/tr [-c ds] [string1 [string2]]</code>				
DESCRIPTION	<p>The <code>tr</code> utility copies the standard input to the standard output with substitution or deletion of selected characters. The arguments <i>string1</i> and <i>string2</i> are considered sets of characters. Any input character found in <i>string1</i> is mapped into the character in the corresponding position within <i>string2</i>. When <i>string2</i> is short, it is padded to the length of <i>string1</i> by duplicating its last character.</p> <p>In either string the notation:</p> <p><i>a-b</i></p> <p>denotes a range of characters from <i>a</i> to <i>b</i> in increasing ASCII order. The character <code>\</code>, followed by 1, 2 or 3 octal digits stands for the character whose ASCII code is given by those digits. As with the shell, the escape character <code>\</code>, followed by any other character, escapes any special meaning for that character.</p>				
OPTIONS	<p>Any combination of the options <code>-c</code>, <code>-d</code>, or <code>-s</code> may be used:</p> <ul style="list-style-type: none"><code>-c</code> Complement the set of characters in <i>string1</i> with respect to the universe of characters whose ASCII codes are 01 through 0377 octal.<code>-d</code> Delete all input characters in <i>string1</i>.<code>-s</code> Squeeze all strings of repeated output characters that are in <i>string2</i> to single characters.				
EXAMPLES	<p>EXAMPLE 1 Creating a list of all the words in a filename</p> <p>The following example creates a list of all the words in <i>filename1</i>, one per line, in <i>filename2</i>, where a word is taken to be a maximal string of alphabetic. The second string is quoted to protect <code>' \ '</code> from the shell. 012 is the ASCII code for NEWLINE.</p> <pre>example% tr -cs A-Za-z '\012' < filename1 > filename2</pre>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWscpu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWscpu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWscpu				
SEE ALSO	<code>ed(1)</code> , <code>ascii(5)</code> , <code>attributes(5)</code>				
NOTES	Will not handle ASCII NUL in <i>string1</i> or <i>string2</i> . <code>tr</code> always deletes NUL from input.				

NAME	trap, onintr – shell built-in functions to respond to (hardware) signals
sh	trap [<i>argument</i> <i>n</i> [<i>n2...</i>]]
cs	onintr [- <i>label</i>]
ksh	*trap [<i>arg</i> <i>sig</i> [<i>sig2...</i>]]
sh	The trap command <i>argument</i> is to be read and executed when the shell receives numeric or symbolic signal(s) (<i>n</i>). (Note: <i>argument</i> is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If <i>argument</i> is absent all trap(s) <i>n</i> are reset to their original values. If <i>argument</i> is the null string this signal is ignored by the shell and by the commands it invokes. If <i>n</i> is 0 the command <i>argument</i> is executed on exit from the shell. The trap command with no arguments prints a list of commands associated with each signal number.
cs	onintr controls the action of the shell on interrupts. With no arguments, onintr restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the - argument, the shell ignores all interrupts. With a <i>label</i> argument, the shell executes a goto <i>label</i> when an interrupt is received or a child process terminates because it was interrupted.
ksh	trap uses <i>arg</i> as a command to be read and executed when the shell receives signal(s) <i>sig</i> . (Note that <i>arg</i> is scanned once when the trap is set and once when the trap is taken.) Each <i>sig</i> can be given as a number or as the name of the signal. trap commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. If <i>arg</i> is omitted or is - , then the trap(s) for each <i>sig</i> are reset to their original values. If <i>arg</i> is the null (the empty string, e.g., "") string then this signal is ignored by the shell and by the commands it invokes. If <i>sig</i> is ERR then <i>arg</i> will be executed whenever a command has a non-zero exit status. If <i>sig</i> is DEBUG then <i>arg</i> will be executed after each command. If <i>sig</i> is 0 or EXIT for a trap set outside any function then the command <i>arg</i> is executed on exit from the shell. The trap command with no arguments prints a list of commands associated with each signal number.

On this man page, **ksh(1)** commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ****** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the **=** sign and word splitting and file name generation are not performed.

trap(1)

NAME	troff – typeset or format documents
SYNOPSIS	troff [-a] [-f] [-F <i>dir</i>] [-i] [-m <i>name</i>] [-n <i>N</i>] [-o <i>list</i>] [-r <i>aN</i>] [-s <i>N</i>] [-T <i>dest</i>] [-u <i>N</i>] [-z] [<i>filename...</i>]
DESCRIPTION	<p>troff formats text in the <i>filenames</i> for typesetting or laser printing. Input to troff is expected to consist of text interspersed with formatting requests and macros. If no <i>filename</i> argument is present, troff reads standard input. A minus sign (-) as a <i>filename</i> indicates that standard input should be read at that point in the list of input files.</p> <p>The output of troff is usually piped through dpost(1) to create a printable postscript file (see EXAMPLES).</p>
OPTIONS	<p>The following options are supported. They may appear in any order, but all must appear before the first <i>filename</i>.</p> <ul style="list-style-type: none"> -a Send an ASCII approximation of formatted output to standard output. (Note: a rough ASCII version can also be printed out on ordinary terminals with an old and rarely used command, /usr/bin/ta.) -f Do not print a trailer after the final page of output or cause the postprocessor to relinquish control of the device. -F<i>dir</i> Search directory <i>dir</i> for font width or terminal tables instead of the system default directory. -i Read standard input after all input files are exhausted. -m<i>name</i> Prepend the macro file /usr/share/lib/tmac/<i>name</i> to the input <i>filenames</i>. Note: most references to macro packages include the leading <i>m</i> as part of the name; for example, the man(5) macros reside in /usr/share/lib/tmac/an. The macro directory can be changed by setting the TROFFMACS environment variable to a specific path. Be certain to include the trailing ' / ' (slash) at the end of the path. -n<i>N</i> Number the first generated page <i>N</i>. -o<i>list</i> Print only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N–M</i> means pages <i>N</i> through <i>M</i>; an initial -<i>N</i> means from the beginning to page <i>N</i>; and a final <i>N–</i> means from <i>N</i> to the end. -q Quiet mode in nroff; ignored in troff. -r<i>aN</i> Set register <i>a</i> (one-character names only) to <i>N</i>. -s<i>N</i> Stop the phototypesetter every <i>N</i> pages. On some devices, troff produces a trailer so you can change cassettes; resume by pressing the typesetter's start button.

troff(1)

- Tdest** Prepare output for typesetter *dest*. The following values can be supplied for *dest*:
- post** A PostScript printer; this is the default value. The output of the **-T** option must go through `dpost(1)` before it is sent to a PostScript printer to obtain the proper output.
 - aps** Autologic APS-5.
- uN** Set the emboldening factor for the font mounted in position 3 to *N*. If *N* is missing, then set the emboldening factor to 0.
- z** Suppress formatted output. Only diagnostic messages and messages output using the `.tm` request are output.

OPERANDS The following operand is supported:

filename The file containing text to be processed by `troff`.

EXAMPLES **EXAMPLE 1** Using `troff`

The following example shows how to print an input text file `mytext`, coded with formatting requests and macros. The input file contains equations and tables and must go through the `tbl(1)` and `eqn(1)` preprocessors before it is formatted by `troff` with `ms` macros, processed by `dpost(1)`, and printed by `lp(1)`:

```
tbl mytext | eqn | troff -ms | dpost | lp
```

FILES

- `/tmp/trtmp` temporary file
- `/usr/share/lib/tmac/*` standard macro files
- `/usr/lib/font/*` font width tables for alternate mounted `troff` fonts
- `/usr/share/lib/nterm/*` terminal driving tables for `nroff`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

SEE ALSO `checknr(1)`, `col(1)`, `dpost(1)`, `eqn(1)`, `lp(1)`, `man(1)`, `nroff(1)`, `tbl(1)`, `attributes(5)`, `man(5)`, `me(5)`, `ms(5)`

NOTES `troff` is not 8-bit clean because it is by design based on 7-bit ASCII.

Previous documentation incorrectly described the numeric register `yr` as being the "Last two digits of current year". `yr` is in actuality the number of years since 1900. To correctly obtain the last two digits of the current year through the year 2099, the definition given below of string register `yy` may be included in a document and subsequently used to display a two-digit year. Note that any other available one- or two-character register name may be substituted for `yy`.

```
.\ " definition of new string register yy--last two digits of year
.\ " use yr (# of years since 1900) if it is < 100
.ie \n(yr<100 .ds yy \n(yr
.el \{
    .\ " else, subtract 100 from yr, store in ny
.nr ny \n(yr-100
.ie \n(ny>9 \{
    .\ " use ny if it is two digits
.ds yy \n(ny
.\ " remove temporary number register ny
.rr ny \}
.el \{.ds yy 0
.\ " if ny is one digit, append it to 0
.as yy \n(ny
.rr ny \} \}
```

true(1)

NAME true, false – provide truth values

SYNOPSIS **true**
false

DESCRIPTION The `true` utility does nothing, successfully. The `false` utility does nothing, unsuccessfully. They are typically used in a shell script `sh` as:

```
while true
do
    command
done
```

which executes *command* forever.

EXIT STATUS `true` has exit status 0.
`false` always will exit with a non-zero value.

NAME	truss – trace system calls and signals
SYNOPSIS	truss [-fcaeildD] [- [tTvX] [!] <i>syscall</i> ,...] [- [sS] [!] <i>signal</i> ,...] [- [mM] [!] <i>fault</i> ,...] [- [rw] [!] <i>fd</i> ,...] [- [uU] [!] <i>lib</i> ,... : [:] [!] <i>func</i> ,...] [-o <i>outfile</i>] <i>command</i> -p <i>pid</i> ...
DESCRIPTION	<p>The <code>truss</code> utility executes the specified command and produces a trace of the system calls it performs, the signals it receives, and the machine faults it incurs. Each line of the trace output reports either the fault or signal name or the system call name with its arguments and return value(s). System call arguments are displayed symbolically when possible using defines from relevant system headers; for any path name pointer argument, the pointed-to string is displayed. Error returns are reported using the error code names described in <code>intro(3)</code>.</p> <p>Optionally (see the <code>-u</code> option), <code>truss</code> will also produce an entry/exit trace of user-level function calls executed by the traced process, indented to indicate nesting.</p>
OPTIONS	<p>The following options are recognized. For those options that take a list argument, the name <code>all</code> can be used as a shorthand to specify all possible members of the list. If the list begins with a <code>!</code>, the meaning of the option is negated (for example, exclude rather than trace). Multiple occurrences of the same option may be specified. For the same name in a list, subsequent options (those to the right) override previous ones (those to the left).</p> <p><code>-p</code> Interprets the <i>command</i> arguments to <code>truss</code> as a list of process-ids for existing processes (see <code>ps(1)</code>) rather than as a command to be executed. <code>truss</code> takes control of each process and begins tracing it provided that the <code>userid</code> and <code>groupid</code> of the process match those of the user or that the user is a privileged user. Processes may also be specified by their names in the <code>/proc</code> directory, for example, <code>/proc/12345</code>.</p> <p><code>-f</code> Follows all children created by <code>fork()</code> or <code>vfork()</code> and includes their signals, faults, and system calls in the trace output. Normally, only the first-level command or process is traced. When <code>-f</code> is specified, the process-id is included with each line of trace output to indicate which process executed the system call or received the signal.</p> <p><code>-c</code> Counts traced system calls, faults, and signals rather than displaying the trace line-by-line. A summary report is produced after the traced command terminates or when <code>truss</code> is interrupted. If <code>-f</code> is also specified, the counts include all traced system calls, faults, and signals for child processes.</p> <p><code>-a</code> Shows the argument strings that are passed in each <code>exec()</code> system call.</p> <p><code>-e</code> Shows the environment strings that are passed in each <code>exec()</code> system call.</p>

truss(1)

- i
Do not display interruptible sleeping system calls. Certain system calls, such as `open()` and `read()` on terminal devices or pipes, can sleep for indefinite periods and are interruptible. Normally, `truss` reports such sleeping system calls if they remain asleep for more than one second. The system call is reported again a second time when it completes. The `-i` option causes such system calls to be reported only once, when they complete.
- l
Includes the id of the responsible lightweight process (*LWP*) with each line of trace output. If `-f` is also specified, both the process-id and the LWP-id are included.
- d
Includes a time stamp on each line of trace output. The time stamp appears as a field containing *seconds .fraction* at the start of the line. This represents a time in seconds relative to the beginning of the trace. The first line of the trace output will show the base time from which the individual time stamps are measured, both as seconds since the epoch (see `time(2)`) and as a date string (see `ctime(3C)` and `date(1)`). The times that are reported are the times that the event in question occurred. For all system calls, the event is the completion of the system call, not the start of the system call.
- D
Includes a time delta on each line of trace output. The value appears as a field containing *seconds .fraction* and represents the elapsed time for the LWP that incurred the event since the last reported event incurred by that LWP. Specifically, for system calls, this is not the time spent within the system call.
- t [!]syscall, . . .
System calls to trace or exclude. Those system calls specified in the comma-separated list are traced. If the list begins with a `!`, the specified system calls are excluded from the trace output. Default is `-tall`.
- T [!]syscall, . . .
System calls that stop the process. The specified system calls are added to the set specified by `-t`. If one of the specified system calls is encountered, `truss` leaves the process stopped and abandoned. That is, `truss` releases the process and exits but leaves the process in the stopped state at completion of the system call in question. A debugger or other process inspection tool (see `proc(1)`) can then be applied to the stopped process. `truss` can be reapplied to the stopped process with the same or different options to continue tracing. Default is `-T!all`.

A process left stopped in this manner cannot be restarted by the application of `kill -CONT` because it is stopped on an event of interest via `/proc`, not by the default action of a stopping signal (see `signal(3HEAD)`). The `prun(1)` command described in `proc(1)` can be used to set the stopped process running again.
- v [!]syscall, . . .
Verbose. Displays the contents of any structures passed by address to the specified system calls (if traced by `-t`). Input values as well as values returned by the

operating system are shown. For any field used as both input and output, only the output value is shown. Default is `-v!all`.

`-x [!]syscall,...`

Displays the arguments to the specified system calls (if traced by `-t`) in raw form, usually hexadecimal, rather than symbolically. This is for unredeemed hackers who must see the raw bits to be happy. Default is `-x!all`.

`-s [!]signal,...`

Signals to trace or exclude. Those signals specified in the comma-separated list are traced. The trace output reports the receipt of each specified signal, even if the signal is being ignored (not blocked). (Blocked signals are not received until they are unblocked.) Signals may be specified by name or number (see `<sys/signal.h>`). If the list begins with a `!`, the specified signals are excluded from the trace output. Default is `-sall`.

`-S [!]signal,...`

Signals that stop the process. The specified signals are added to the set specified by `-s`. If one of the specified signals is received, `truss` leaves the process stopped and abandoned (see the `-T` option). Default is `-S!all`.

`-m [!]fault,...`

Machine faults to trace or exclude. Those faults specified in the comma-separated list are traced. Faults may be specified by name or number (see `<sys/fault.h>`). If the list begins with a `!`, the specified faults are excluded from the trace output. Default is `-mall -m!fltpage`.

`-M [!]fault,...`

Machine faults that stop the process. The specified faults are added to the set specified by `-m`. If one of the specified faults is incurred, `truss` leaves the process stopped and abandoned (see the `-T` option). Default is `-M!all`.

`-r [!]fd,...`

Shows the full contents of the I/O buffer for each `read()` on any of the specified file descriptors. The output is formatted 32 bytes per line and shows each byte as an ASCII character (preceded by one blank) or as a 2-character C language escape sequence for control characters such as horizontal tab (`\t`) and newline (`\n`). If ASCII interpretation is not possible, the byte is shown in 2-character hexadecimal representation. (The first 12 bytes of the I/O buffer for each traced `read()` are shown even in the absence of `-r`.) Default is `-r!all`.

`-w [!]fd,...`

Shows the contents of the I/O buffer for each `write()` on any of the specified file descriptors (see the `-r` option). Default is `-w!all`.

`-u [!]lib, ... : [!]func, ...`

User-level function call tracing. `lib, ...` is a comma-separated list of dynamic library names, excluding the `".so.n"` suffix. `func, ...` is a comma-separated list of function names. In both cases the names can include name-matching metacharacters `*`, `?`, `[]` with the same meanings as those of `sh(1)` but as applied to the library/function name spaces, not to files. An empty library or function list defaults to `*`, trace all libraries or functions in a library. A leading `!` on either list specifies an exclusion

truss(1)

list, names of libraries or functions not to be traced. Excluding a library excludes all functions in that library; any function list following a library exclusion list is ignored.

A single `:` separating the library list from the function list means to trace calls into the libraries from outside the libraries, but omit calls made to functions in a library from other functions in the same library. A double `: :` means to trace all calls, regardless of origin.

Library patterns do not match either the executable file or the dynamic linker unless there is an exact match (`l*` will not match `ld.so.1`). To trace functions in either of these objects, the names must be specified exactly, as in: `truss -u a.out -u ld ... a.out` is the literal name to be used for this purpose; it does not stand for the name of the executable file. Tracing `a.out` function calls implies all calls (default is `: :`).

Multiple `-u` options may be specified and they are honored left-to-right. If the process is linked with `-lthread`, the id of the thread that performed the function call is included in the trace output for the call. `truss` searches the dynamic symbol table in each library to find function names and will also search the standard symbol table if it has not been stripped.

`-U [!]lib, ... :[:][!]func, ...`

User-level function calls that stop the process. The specified functions are added to the set specified by `-u`. If one of the specified functions is called, `truss` leaves the process stopped and abandoned (see the `-T` option).

`-o outfile`

File to be used for the trace output. By default, the output goes to standard error.

See *man pages section 2: System Calls* for system call names accepted by the `-t`, `-T`, `-v`, and `-x` options. System call numbers are also accepted.

If `truss` is used to initiate and trace a specified command and if the `-o` option is used or if standard error is redirected to a non-terminal file, then `truss` runs with hangup, interrupt, and quit signals ignored. This facilitates tracing of interactive programs that catch interrupt and quit signals from the terminal.

If the trace output remains directed to the terminal, or if existing processes are traced (the `-p` option), then `truss` responds to hangup, interrupt, and quit signals by releasing all traced processes and exiting. This enables the user to terminate excessive trace output and to release previously-existing processes. Released processes continue normally, as though they had never been touched.

EXAMPLES

EXAMPLE 1 Tracing a command

This example produces a trace of the `find(1)` command on the terminal:

```
example$ truss find . -print >find.out
```

EXAMPLE 1 Tracing a command *(Continued)***EXAMPLE 2** Tracing common system calls

To see only a trace of the open, close, read, and write system calls:

```
example$ truss -t open,close,read,write find . -print >find.out
```

EXAMPLE 3 Tracing a shell script

This produces a trace of the `spell(1)` command on the file `truss.out`:

```
example$ truss -f -o truss.out spell document
```

`spell` is a shell script, so the `-f` flag is needed to trace not only the shell but also the processes created by the shell. (The `spell` script runs a pipeline of eight processes.)

EXAMPLE 4 Abbreviating output

A particularly boring example is:

```
example$ truss nroff -mm document >nroff.out
```

because 97% of the output reports `lseek()`, `read()`, and `write()` system calls. To abbreviate it:

```
example$ truss -t ! lseek,read,write nroff -mm document >nroff.out
```

EXAMPLE 5 Tracing library calls from outside the C library

This example traces all user-level calls made to any function in the C library from outside the C library:

```
example$ truss -u libc . . .
```

EXAMPLE 6 Tracing library calls from within the C library

This example includes calls made to functions in the C library from within the C library itself:

```
example$ truss -u libc : : . . .
```

EXAMPLE 7 Tracing library calls other than the C library

This example traces all user-level calls made to any library other than the C library:

```
example$ truss -u '*' -u !libc . . .
```

EXAMPLE 8 Tracing printf and scanf function calls

This example traces all user-level calls to functions in the `printf` and `scanf` family contained in the C library:

truss(1)

EXAMPLE 8 Tracing printf and scanf function calls (Continued)

```
example$ truss -u 'libc : *printf,*scanf' . . .
```

EXAMPLE 9 Tracing any user-level function call

This example traces every user-level function call from anywhere to anywhere:

```
example$ truss -u a.out -u ld : : -u : : . . .
```

EXAMPLE 10 Tracing a system call verbosely

This example verbosely traces the system call activity of process #1, `init(1M)` (if you are a privileged user):

```
example# truss -p -v all 1
```

Interrupting `truss` returns `init` to normal operation.

FILES /proc/* process files

man pages section 2: System Calls

NOTES Some of the system calls described in *man pages section 2: System Calls* differ from the actual operating system interfaces. Do not be surprised by minor deviations of the trace output from the descriptions in that document.

Every machine fault (except a page fault) results in the posting of a signal to the LWP that incurred the fault. A report of a received signal will immediately follow each report of a machine fault (except a page fault) unless that signal is being blocked.

The operating system enforces certain security restrictions on the tracing of processes. In particular, any command whose object file (`a.out`) cannot be read by a user cannot be traced by that user; `set-uid` and `set-gid` commands can be traced only by a privileged user. Unless it is run by a privileged user, `truss` loses control of any process that performs an `exec()` of a `set-id` or unreadable object file; such processes continue normally, though independently of `truss`, from the point of the `exec()`.

To avoid collisions with other controlling processes, `truss` will not trace a process that it detects is being controlled by another process via the `/proc` interface. This allows `truss` to be applied to `proc(4)`-based debuggers as well as to another instance of itself.

The trace output contains tab characters under the assumption that standard tab stops are set (every eight positions).

The trace output for multiple processes or for a multithreaded process (one that contains more than one LWP) is not produced in strict time order. For example, a `read()` on a pipe may be reported before the corresponding `write()`. For any one LWP (a traditional process contains only one), the output is strictly time-ordered.

When tracing more than one process, `truss` runs as one controlling process for each process being traced. For the example of the `spell` command shown above, `spell` itself uses 9 process slots, one for the shell and 8 for the 8-member pipeline, while `truss` adds another 9 processes, for a total of 18.

Not all possible structures passed in all possible system calls are displayed under the `-v` option.

tset(1B)

NAME	tset, reset – establish or restore terminal characteristics
SYNOPSIS	tset [-InQrs] [-ec] [-kc] [-m [port-ID [baudrate] : type...]] [type] reset [-] [-ec] [-I] [-kc] [-n] [-Q] [-r] [-s] [-m [indent] [test baudrate] : type...]] [type]
DESCRIPTION	<p>The <code>tset</code> utility sets up your terminal, typically when you first log in. It does terminal dependent processing such as setting erase and kill characters, setting or resetting delays, sending any sequences needed to properly initialize the terminal, and the like. <code>tset</code> first determines the <code>type</code> of terminal involved, and then does necessary initializations and mode settings. If a port is not wired permanently to a specific terminal (not hardwired) it is given an appropriate generic identifier such as <code>dialup</code>.</p> <p><code>reset</code> clears the terminal settings by turning off CBREAK and RAW modes, output delays and parity checking, turns on NEWLINE translation, echo and TAB expansion, and restores undefined special characters to their default state. It then sets the modes as usual, based on the terminal type (which will probably override some of the above). See <code>stty(1)</code> for more information. All arguments to <code>tset</code> may be used with <code>reset</code>. <code>reset</code> also uses <code>rs=</code> and <code>rf=</code> to reset the initialization string and file. This is useful after a program dies and leaves the terminal in a funny state. Often in this situation, characters will not echo as you type them. You may have to type <code>LINEFEED reset LINEFEED</code> since <code>RETURN</code> may not work.</p> <p>When no arguments are specified, <code>tset</code> reads the terminal type from the <code>TERM</code> environment variable and re-initializes the terminal, and performs initialization of mode, environment and other options at login time to determine the terminal type and set up terminal modes.</p> <p>When used in a startup script (<code>.profile</code> for <code>sh(1)</code> users or <code>.login</code> for <code>csh(1)</code> users) it is desirable to give information about the type of terminal you will usually use on ports that are not hardwired. Any of the alternate generic names given in the file <code>/etc/termcap</code> are possible identifiers. Refer to the <code>-m</code> option below for more information. If no mapping applies and a final <code>type</code> option, not preceded by a <code>-m</code>, is given on the command line then that <code>type</code> is used.</p> <p>It is usually desirable to return the terminal type, as finally determined by <code>tset</code>, and information about the terminal's capabilities, to a shell's environment. This can be done using the <code>-</code>, <code>-s</code>, or <code>-S</code> options.</p> <p>For the Bourne shell, put this command in your <code>.profile</code> file:</p> <pre>eval `tset -s options...`</pre> <p>or using the C shell, put these commands in your <code>.login</code> file:</p> <pre>set noglob eval `tset -s options...`unset noglob</pre> <p>With the C shell, it is also convenient to make an alias in your <code>.cshrc</code> file:</p> <pre>alias ts `eval `tset -s \!*``</pre>

This also allows the command:

```
ts 2621
```

to be invoked at any time to set the terminal and environment. It is not possible to get this aliasing effect with a Bourne shell script, because shell scripts cannot set the environment of their parent. If a process could set its parent's environment, none of this nonsense would be necessary in the first place.

Once the terminal type is known, `tset` sets the terminal driver mode. This normally involves sending an initialization sequence to the terminal, setting the single character erase (and optionally the line-kill (full line erase)) characters, and setting special character delays. TAB and NEWLINE expansion are turned off during transmission of the terminal initialization sequence.

On terminals that can backspace but not overstrike (such as a CRT), and when the erase character is '#', the erase character is changed as if `-e` had been used.

OPTIONS

- The name of the terminal finally decided upon is output on the standard output. This is intended to be captured by the shell and placed in the `TERM` environment variable.
- ec Set the erase character to be the named character *c* on all terminals. Default is the BACKSPACE key on the keyboard, usually `^H` (CTRL-H). The character *c* can either be typed directly, or entered using the circumflex-character notation used here.
- ic Set the interrupt character to be the named character *c* on all terminals. Default is `^C` (CTRL-C). The character *c* can either be typed directly, or entered using the circumflex-character notation used here.
- I Suppress transmitting terminal-initialization strings.
- kc Set the line kill character to be the named character *c* on all terminals. Default is `^U` (CTRL-U). The kill character is left alone if `-k` is not specified. Control characters can be specified by prefixing the alphabetical character with a circumflex (as in CTRL-U) instead of entering the actual control key itself. This allows you to specify control keys that are currently assigned.
- n Specify that the new tty driver modes should be initialized for this terminal. Probably useless since `stty new` is the default.
- Q Suppress printing the 'Erase set to' and 'Kill set to' messages.
- r In addition to other actions, reports the terminal type.
- s Output commands to set and export `TERM`. This can be used with

```
set noglob
eval 'tset -s . . . .'
unset noglob
```

tset(1B)

to bring the terminal information into the environment. Doing so makes programs such as `vi(1)` start up faster. If the `SHELL` environment variable ends with `csh`, C shell commands are output, otherwise Bourne shell commands are output.

```
-m [ port-ID [ baudrate ] : type ] . . .
```

Specify (map) a terminal type when connected to a generic port (such as *dialup* or *plugboard*) identified by *port-ID*. The *baudrate* argument can be used to check the baudrate of the port and set the terminal type accordingly. The target rate is prefixed by any combination of the following operators to specify the conditions under which the mapping is made:

>	Greater than
@	Equals or "at"
<	Less than
!	It is not the case that (negates the above operators)
?	Prompt for the terminal type. If no response is given, then <code>type</code> is selected by default.

In the following example, the terminal type is set to `adm3a` if the port is a dialup with a speed of greater than 300 or to `dw2` if the port is a dialup at 300 baud or less. In the third case, the question mark preceding the terminal type indicates that the user is to verify the type desired. A `NULL` response indicates that the named type is correct. Otherwise, the user's response is taken to be the type desired.

```
tset -m 'dialup>300:adm3a' -m 'dialup:dw2' -m 'plugboard:?adm3a'
```

To prevent interpretation as metacharacters, the entire argument to `-m` should be enclosed in single quotes. When using the C shell, exclamation points should be preceded by a backslash (`\`).

EXAMPLES These examples all use the `'-'` option. A typical use of `tset` in a `.profile` or `.login` will also use the `-e` and `-k` options, and often the `-n` or `-Q` options as well. These options have been omitted here to keep the examples short.

EXAMPLE 1 Selecting a terminal

To select a 2621, you might put the following sequence of commands in your `.login` file (or `.profile` for Bourne shell users).

```
set noglob
eval `tset -s 2621`
unset noglob
```

If you want to make the selection based only on the baud rate, you might use the following:

```
set noglob
eval `tset -s -m '>1200:wy' 2621`
unset noglob
```

EXAMPLE 1 Selecting a terminal (Continued)**EXAMPLE 2** Selecting terminals according to speed or baud rate

If you have a switch which connects to various ports (making it impractical to identify which port you may be connected to), and use various terminals from time to time, you can select from among those terminals according to the *speed* or baud rate. In the example below, `tset` will prompt you for a terminal type if the baud rate is greater than 1200 (say, 9600 for a terminal connected by an RS-232 line), and use a Wyse® 50 by default. If the baud rate is less than or equal to 1200, it will select a 2621. Note the placement of the question mark, and the quotes to protect the `>` and `?` from interpretation by the shell.

```
set noglob
eval `tset -s -m 'switch>1200:?wy' -m 'switch<=1200:2621'`
unset noglob
```

EXAMPLE 3 Selecting the terminal used most often

The following entry is appropriate if you always dial up, always at the same baud rate, on many different kinds of terminals, and the terminal you use most often is an `adm3a`.

```
set noglob
eval `tset -s ?adm3a`
unset noglob
```

EXAMPLE 4 Selecting a terminal with specific settings

The following example quietly sets the erase character to BACKSPACE, and kill to CTRL-U. If the port is switched, it selects a Concept™ 100 for speeds less than or equal to 1200, and asks for the terminal type otherwise (the default in this case is a Wyse 50). If the port is a direct dialup, it selects Concept 100 as the terminal type. If logging in over the ARPANET, the terminal type selected is a Datamedia® 2500 terminal or emulator. Note the backslash escaping the NEWLINE at the end of the first line in the example.

```
set noglob
eval `tset -e -k^U -Q -s -m 'switch<=1200:concept100' -m\
'switch:?wy' -m dialup:concept100 -m arpanet:dm2500`
unset noglob
```

tset(1B)

EXAMPLE 4 Selecting a terminal with specific settings (Continued)

FILES .login
.profile

NOTES The `tset` command is one of the first commands a user must master when getting started on a UNIX system. Unfortunately, it is one of the most complex, largely because of the extra effort the user must go through to get the environment of the `login` shell set. Something needs to be done to make all this simpler, either the `login` program should do this stuff, or a default shell alias should be made, or a way to set the environment of the parent should exist.

This program cannot intuit personal choices for erase, interrupt and line kill characters, so it leaves these set to the local system standards.

It could well be argued that the shell should be responsible for ensuring that the terminal remains in a sane state; this would eliminate the need for the `reset` program.

NAME	tsort – topological sort
SYNOPSIS	<code>/usr/ccs/bin/tsort</code> [<i>file</i>]
DESCRIPTION	<p>The <code>tsort</code> command produces on the standard output a totally ordered list of items consistent with a partial ordering of items mentioned in the input <i>file</i>.</p> <p>The input consists of pairs of items (nonempty strings) separated by blanks. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>file</i> A path name of a text file to order. If no <i>file</i> operand is given, the standard input is used.</p>
EXAMPLES	<p>EXAMPLE 1 An example of the <code>tsort</code> command</p> <p>The command:</p> <pre>example% tsort <<EOF a b c c d e g g f g e f EOF</pre> <p>produces the output:</p> <pre>a b c d e f g</pre>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>tsort</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>>0 An error occurred.</p>

DIAGNOSTICS | Odd data: there are an odd number of fields in the input file.

NAME	tty – return user’s terminal name								
SYNOPSIS	tty [-l] [-s]								
DESCRIPTION	The tty utility writes to the standard output the name of the terminal that is open as standard input. The name that is used is equivalent to the string that would be returned by the ttyname(3C) function.								
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -l Prints the synchronous line number to which the user’s terminal is connected, if it is on an active synchronous line. -s Inhibits printing of the terminal path name, allowing one to test just the exit status. 								
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of tty: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.								
EXIT STATUS	The following exit values are returned: <ul style="list-style-type: none"> 0 Standard input is a terminal. 1 Standard input is not a terminal. >1 An error occurred. 								
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1" data-bbox="459 1096 1425 1278" style="margin-left: 20px;"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>CSI</td> <td>enabled</td> </tr> <tr> <td>Interface Stability</td> <td>Standard</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	CSI	enabled	Interface Stability	Standard
ATTRIBUTE TYPE	ATTRIBUTE VALUE

CSI	enabled								
Interface Stability	Standard								
SEE ALSO	isatty(3C), ttyname(3C), attributes(5), environ(5), standards(5)								
DIAGNOSTICS	not on an active synchronous line The standard input is not a synchronous terminal and -l is specified. not a tty The standard input is not a terminal and -s is not specified.								
NOTES	The -s option is useful only if the exit status is wanted. It does not rely on the ability to form a valid path name. Portable applications should use test -t.								

type(1)

NAME	type – write a description of command type
SYNOPSIS	type <i>name</i> ...
DESCRIPTION	<p>The <code>type</code> utility indicates how each <i>name</i> operand would be interpreted if used as a command. <code>type</code> displays information about each operand identifying the operand as a shell built-in, function, alias, hashed command, or keyword, and where applicable, may display the operand's path name.</p> <p>There is also a shell built-in version of <code>type</code> that is similar to the <code>type</code> utility.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>name</i> A name to be interpreted.</p>
ENVIRONMENT VARIABLES	<p>See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>type</code>: <code>LANG</code>, <code>LC_ALL</code>, <code>LC_CTYPE</code>, <code>LC_MESSAGES</code>, and <code>NLSPATH</code>.</p> <p><code>PATH</code> Determine the location of <i>name</i>.</p>
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>>0 An error occurred.</p>
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

SEE ALSO `typeset(1)`, `attributes(5)`, `environ(5)`, `standards(5)`

NAME	typeset, whence – shell built-in functions to set/get attributes and values for shell variables and functions
SYNOPSIS	typeset [\pm HLRZfilrtux [<i>n</i>]] [<i>name</i> [= <i>value</i>]]... whence [-pv] <i>name</i> ...
DESCRIPTION	<p>typeset sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables <i>name</i> is created. The variables <i>value</i> and <code>type</code> are restored when the function completes. The following list of attributes may be specified:</p> <ul style="list-style-type: none"> -H This flag provides UNIX to host-name file mapping on non-UNIX machines. -L Left justify and remove leading blanks from <i>value</i>. If <i>n</i> is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the -Z flag is also set. The -R flag is turned off. -R Right justify and fill with leading blanks. If <i>n</i> is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The -L flag is turned off. -Z Right justify and fill with leading zeros if the first non-blank character is a digit and the -L flag has not been set. If <i>n</i> is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. -f The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are -t, -u and -x. The flag -t turns on execution tracing for this function. The flag -u causes this function to be marked undefined. The FPATH variable will be searched to find the function definition when the function is referenced. The flag -x allows the function definition to remain in effect across shell procedures invoked by name. -i Parameter is an integer. This makes arithmetic faster. If <i>n</i> is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base. -l All upper-case characters are converted to lower-case. The upper-case flag, -u is turned off. -r The given <i>names</i> are marked readonly and these names cannot be changed by subsequent assignment. -t Tags the variables. Tags are user definable and have no special meaning to the shell.

typeset(1)

- u All lower-case characters are converted to upper-case characters. The lower-case flag, -l is turned off.
- x The given *names* are marked for automatic export to the environment of subsequently-executed commands.

The -i attribute can not be specified along with -R, -L, -Z, or -f.

Using + rather than - causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using + rather than - keeps the values from being printed.) If no *names* and flags are given, the *names* and *attributes* of all *variables* are printed.

For each *name*, *whence* indicates how it would be interpreted if used as a command name.

The -v flag produces a more verbose report.

The -p flag does a path search for *name* even if name is an alias, a function, or a reserved word.

On this man page, ksh(1) commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME ucblinks – adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices

SYNOPSIS `/usr/ucb/ucblinks [-e rulebase] [-r rootdir]`

DESCRIPTION ucblinks creates symbolic links under the /dev directory for devices whose SunOS 5.x names differ from their SunOS 4.x names. Where possible, these symbolic links point to the device's SunOS 5.x name rather than to the actual /devices entry.

ucblinks does not remove unneeded compatibility links; these must be removed by hand.

ucblinks should be called each time the system is reconfiguration-booted, after any new SunOS 5.x links that are needed have been created, since the reconfiguration may have resulted in more compatibility names being needed.

In releases prior to SunOS 5.4, ucblinks used a `nawk` rule-base to construct the SunOS 4.x compatible names. ucblinks no longer uses `nawk` for the default operation, although `nawk` rule-bases can still be specified with the `-e` option. The `nawk` rule-base equivalent to the SunOS 5.4 default operation can be found in `/usr/ucblib/ucblinks.awk`.

OPTIONS

- `-e rulebase` Specify *rulebase* as the file containing `nawk(1)` pattern-action statements.
- `-r rootdir` Specify *rootdir* as the directory under which `dev` and `devices` will be found, rather than the standard root directory `/`.

FILES `/usr/ucblib/ucblinks.awk` sample rule-base for compatibility links

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ul(1)

NAME | ul – do underlining

SYNOPSIS | **ul** [-i] [-t *terminal*] [*filename...*]

DESCRIPTION | ul reads the named *filenames* (or the standard input if none are given) and translates occurrences of underscores to the sequence which indicates underlining for the terminal in use, as specified by the environment variable TERM. ul uses the /usr/share/lib/terminfo entry to determine the appropriate sequences for underlining. If the terminal is incapable of underlining, but is capable of a standout mode then that is used instead. If the terminal can overstrike, or handles underlining automatically, ul degenerates to cat(1). If the terminal cannot underline, underlining is ignored.

OPTIONS | -t *terminal* | Override the terminal kind specified in the environment. If the terminal cannot underline, underlining is ignored. If the terminal name is not found, no underlining is attempted.

| -i | Indicate underlining by a separate line containing appropriate dashes '-'; this is useful when you want to look at the underlining which is present in an nroff(1) output stream on a CRT-terminal.

RETURN VALUES | ul returns exit code 1 if the file specified is not found.

FILES | /usr/share/lib/terminfo/*

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

SEE ALSO | cat(1), man(1), nroff(1), attributes(5)

BUGS | nroff usually generates a series of backspaces and underlines intermixed with the text to indicate underlining. ul makes attempt to optimize the backward motion.

NAME	umask – get or set the file mode creation mask
SYNOPSIS	<code>/usr/bin/umask [-S] [mask]</code>
sh	<code>umask [000]</code>
csk	<code>umask [000]</code>
ksh	<code>umask [-S] [mask]</code>
DESCRIPTION	<p>The <code>umask</code> utility sets the file mode creation mask of the current shell execution environment to the value specified by the <i>mask</i> operand. This mask affects the initial value of the file permission bits of subsequently created files. If <code>umask</code> is called in a subshell or separate utility execution environment, such as one of the following:</p> <pre>(umask 002) nohup umask ... find . -exec umask ...</pre> <p>it does not affect the file mode creation mask of the caller's environment. For this reason, the <code>/usr/bin/umask</code> utility cannot be used to change the <code>umask</code> in an ongoing session. Its usefulness is limited to checking the caller's <code>umask</code>. To change the <code>umask</code> of an ongoing session you must use one of the shell builtins.</p> <p>If the <i>mask</i> operand is not specified, the <code>umask</code> utility writes the value of the invoking process's file mode creation mask to standard output.</p> <p>sh The user file-creation mode mask is set to <i>000</i>. The three octal digits refer to read/write/execute permissions for owner, group, and other, respectively (see <code>chmod(1)</code>, <code>chmod(2)</code>, and <code>umask(2)</code>). The value of each specified digit is subtracted from the corresponding "digit" specified by the system for the creation of a file (see <code>creat(2)</code>). For example, <code>umask 022</code> removes write permission for group and other (files normally created with mode <code>777</code> become mode <code>755</code>. Files created with mode <code>666</code> become mode <code>644</code>).</p> <ul style="list-style-type: none"> ■ If <i>000</i> is omitted, the current value of the mask is printed. ■ <code>umask</code> is recognized and executed by the shell. ■ <code>umask</code> can be included in the user's <code>.profile</code> (see <code>profile(4)</code>) and invoked at login to automatically set the user's permissions on files or directories created. <p>csk See the description above for the Bourne shell (<code>sh</code>)<code>umask</code> built-in.</p> <p>ksh The user file-creation mask is set to <i>mask</i>. <i>mask</i> can either be an octal number or a symbolic value as described in <code>chmod(1)</code>. If a symbolic value is given, the new <code>umask</code> value is the complement of the result of applying <i>mask</i> to the complement of the previous <code>umask</code> value. If <i>mask</i> is omitted, the current value of the mask is printed.</p> <p>OPTIONS The following option is supported:</p> <p><code>-S</code> Produces symbolic output.</p>

umask(1)

The default output style is unspecified, but will be recognized on a subsequent invocation of `umask` on the same system as a *mask* operand to restore the previous file mode creation mask.

OPERANDS The following operand is supported:

mask A string specifying the new file mode creation mask. The string is treated in the same way as the *mode* operand described in the `chmod(1)` manual page.

For a *symbolic_mode* value, the new value of the file mode creation mask is the logical complement of the file permission bits portion of the file mode specified by the *symbolic_mode* string.

In a *symbolic_mode* value, the permissions *op* characters `+` and `-` are interpreted relative to the current file mode creation mask. `+` causes the bits for the indicated permissions to be cleared in the mask. `-` causes the bits of the indicated permissions to be set in the mask.

The interpretation of *mode* values that specify file mode bits other than the file permission bits is unspecified.

The file mode creation mask is set to the resulting numeric value.

The default output of a prior invocation of `umask` on the same system with no operand will also be recognized as a *mask* operand. The use of an operand obtained in this way is not obsolescent, even if it is an octal number.

OUTPUT When the *mask* operand is not specified, the `umask` utility will write a message to standard output that can later be used as a `umask mask` operand.

If `-s` is specified, the message will be in the following format:

```
"u=%s,g=%s,o=%s\n", owner permissions, group permissions, \
                        other permissions
```

where the three values will be combinations of letters from the set `{r, w, x}`. The presence of a letter will indicate that the corresponding bit is clear in the file mode creation mask.

If a *mask* operand is specified, there will be no output written to standard output.

EXAMPLES **EXAMPLE 1** Using the `umask` command

Either of the commands:

```
umask a=rx,ug+w
umask 002
```

sets the mode mask so that subsequently created files have their `S_IWOTH` bit cleared.

EXAMPLE 1 Using the umask command (Continued)

After setting the mode mask with either of the above commands, the `umask` command can be used to write the current value of the mode mask:

```
example$ umask
0002
```

The output format is unspecified, but historical implementations use the obsolescent octal integer mode format.

```
example$ umask -S
u=rwx,g=rwx,o=rwx
```

Either of these outputs can be used as the mask operand to a subsequent invocation of the `umask` utility.

Assuming the mode mask is set as above, the command:

```
umask g-w
```

sets the mode mask so that subsequently created files have their `S_IWGRP` and `S_IWOTH` bits cleared.

The command:

```
umask --w
```

sets the mode mask so that subsequently created files have all their write bits cleared. Notice that *mask* operands `r`, `w`, `x`, or anything beginning with a hyphen (`-`), must be preceded by `-` to keep it from being interpreted as an option.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `umask`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 The file mode creation mask was successfully changed, or no *mask* operand was supplied.
- >0 An error occurred.

NAME	uname – print name of current system
SYNOPSIS	<pre>uname [-aimnprsvX] uname [-S <i>system_name</i>]</pre>
DESCRIPTION	<p>The <code>uname</code> utility prints information about the current system on the standard output. When options are specified, symbols representing one or more system characteristics will be written to the standard output. If no options are specified, <code>uname</code> prints the current operating system's name. The options print selected information returned by <code>uname(2)</code>, <code>sysinfo(2)</code>, or both.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Prints basic information currently available from the system. -i Prints the name of the hardware implementation (platform). -m Prints the machine hardware name (class). Use of this option is discouraged; use <code>uname -p</code> instead. See NOTES section below. -n Prints the nodename (the nodename is the name by which the system is known to a communications network). -p Prints the current host's ISA or processor type. -r Prints the operating system release level. -s Prints the name of the operating system. This is the default. -S <i>system_name</i> The nodename may be changed by specifying a system name argument. The system name argument is restricted to <code>SYS_NMLN</code> characters. <code>SYS_NMLN</code> is an implementation specific value defined in <code><sys/utsname.h></code>. Only the super-user is allowed this capability. This change does not persist across reboots of the system. Use <code>sys-unconfig(1M)</code> to change a host's name permanently. -v Prints the operating system version. -X Prints expanded system information, one information element per line, as expected by SCO UNIX. The displayed information includes: <ul style="list-style-type: none"> ■ system name, node, release, version, machine, and number of CPUs. ■ BusType, Serial, and Users (set to "unknown" in Solaris) ■ OEM# and Origin# (set to 0 and 1, respectively)
EXAMPLES	<p>EXAMPLE 1 Printing the OS name and release level</p> <p>The following command:</p> <pre>example% uname -sr</pre>

uname(1)

EXAMPLE 1 Printing the OS name and release level (Continued)

prints the operating system name and release level, separated by one SPACE character.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uname`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

SYSV3 This variable is used to override the default behavior of `uname`. This is necessary to make it possible for some INTERACTIVE UNIX Systems and SCO UNIX programs and scripts to work properly. Many scripts use `uname` to determine the `SYSV3` type or the version of the OS to ensure software is compatible with that OS. Setting `SYSV3` to an empty string will make `uname` print the following default values:

```
nodename nodename 3.2 2 i386
```

The individual elements that `uname` displays can also be modified by setting `SYSV3` in the following format:

os,sysname,node,rel,ver,mach

<i>os</i>	Operating system (IUS or SCO).
<i>sysname</i>	System name.
<i>node</i>	Nodename as displayed by the <code>-n</code> option.
<i>rel</i>	Release level as displayed by the <code>-r</code> option.
<i>ver</i>	Version number as displayed by the <code>-v</code> option.
<i>mach</i>	Machine name as displayed by <code>-m</code> option.

Do not put spaces between the elements. If an element is omitted, the current system value will be used.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

SEE ALSO arch(1), isalist(1), sys-unconfig(1M), sysinfo(2), uname(2), nodename(4), attributes(5), environ(5), standards(5)

NOTES Independent software vendors (ISVs) and others who need to determine detailed characteristics of the platform on which their software is either being installed or executed should use the `uname` command.

To determine the operating system name and release level, use `uname -sr`. To determine only the operating system release level, use `uname -r`. Notice that operating system release levels are not guaranteed to be in *x.y* format (such as 5.3, 5.4, 5.5, and so forth); future releases could be in the *x.y.z* format (such as 5.3.1, 5.3.2, 5.4.1, and so forth).

In SunOS 4.x releases, the `arch(1)` command was often used to obtain information similar to that obtained by using the `uname` command. The `arch(1)` command output "sun4" was often incorrectly interpreted to signify a SunOS SPARC system. If hardware platform information is desired, use `uname -sp`.

The `arch -k` and `uname -m` commands return equivalent values; however, the use of either of these commands by third party programs is discouraged, as is the use of the `arch` command in general. To determine the machine's Instruction Set Architecture (ISA or processor type), use `uname` with the `-p` option.

unifdef(1)

NAME	unifdef – resolve and remove ifdef'ed lines from C program source
SYNOPSIS	unifdef [-c] [-D <i>name</i>] [-U <i>name</i>] [-iD <i>name</i>] [-iU <i>name</i>] ... [<i>filename</i>]
DESCRIPTION	<p>unifdef removes <code>ifdef</code>d lines from a file while otherwise leaving the file alone. It is smart enough to deal with the nested <code>ifdef</code>s, comments, single and double quotes of C syntax, but it does not do any including or interpretation of macros. Neither does it strip out comments, though it recognizes and ignores them. You specify which symbols you want defined with <code>-D</code> options, and which you want undefined with <code>-U</code> options. Lines within those <code>ifdef</code>s will be copied to the output, or removed, as appropriate. Any <code>ifdef</code>, <code>ifndef</code>, <code>else</code>, and <code>endif</code> lines associated with <i>filename</i> will also be removed.</p> <p><code>ifdef</code>s involving symbols you do not specify are untouched and copied out along with their associated <code>ifdef</code>, <code>else</code>, and <code>endif</code> lines.</p> <p>If an <code>ifdefX</code> occurs nested inside another <code>ifdefX</code>, then the inside <code>ifdef</code> is treated as if it were an unrecognized symbol. If the same symbol appears in more than one argument, only the first occurrence is significant.</p> <p>unifdef copies its output to the standard output and will take its input from the standard input if no <i>filename</i> argument is given.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-c Complement the normal operation. Lines that would have been removed or blanked are retained, and vice versa.-l Replace "lines removed" lines with blank lines.-t Plain text option. unifdef refrains from attempting to recognize comments and single and double quotes.-D<i>name</i> Lines associated with the defined symbol <i>name</i>.-U<i>name</i> Lines associated with the undefined symbol <i>name</i>.-iD<i>name</i> Ignore, but print out, lines associated with the defined symbol <i>name</i>. If you use <code>ifdef</code>s to delimit non-C lines, such as comments or code which is under construction, then you must tell unifdef which symbols are used for that purpose so that it will not try to parse for quotes and comments within them.-iU<i>name</i> Ignore, but print out, lines associated with the undefined symbol <i>name</i>.
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none">0 Successful operation.1 Operation failed.

uniq(1)

NAME	uniq – report or filter out repeated lines in a file
SYNOPSIS	uniq [-c -d -u] [-f <i>fields</i>] [-s <i>char</i>] [<i>input_file</i> [<i>output_file</i>]] uniq [-c -d -u] [-n] [+ <i>m</i>] [<i>input_file</i> [<i>output_file</i>]]
DESCRIPTION	<p>The <code>uniq</code> utility will read an input file comparing adjacent lines, and write one copy of each input line on the output. The second and succeeding copies of repeated adjacent input lines will not be written.</p> <p>Repeated lines in the input will not be detected if they are not adjacent.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-c Precedes each output line with a count of the number of times the line occurred in the input.-d Suppresses the writing of lines that are not repeated in the input.-f <i>fields</i> Ignores the first <i>fields</i> fields on each input line when doing comparisons, where <i>fields</i> is a positive decimal integer. A field is the maximal string matched by the basic regular expression: [[:blank:]]* [^[[:blank:]]]* If <i>fields</i> specifies more fields than appear on an input line, a null string will be used for comparison.-s <i>chars</i> Ignores the first <i>chars</i> characters when doing comparisons, where <i>chars</i> is a positive decimal integer. If specified in conjunction with the -f option, the first <i>chars</i> characters after the first <i>fields</i> fields will be ignored. If <i>chars</i> specifies more characters than remain on an input line, a null string will be used for comparison.-u Suppresses the writing of lines that are repeated in the input.-n Equivalent to -f <i>fields</i> with <i>fields</i> set to <i>n</i>.+<i>m</i> Equivalent to -s <i>chars</i> with <i>chars</i> set to <i>m</i>.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"><i>input_file</i> A path name of the input file. If <i>input_file</i> is not specified, or if the <i>input_file</i> is -, the standard input will be used.<i>output_file</i> A path name of the output file. If <i>output_file</i> is not specified, the standard output will be used. The results are unspecified if the file named by <i>output_file</i> is the file named by <i>input_file</i>.
EXAMPLES	<p>EXAMPLE 1 Using the <code>uniq</code> command</p> <p>The following example lists the contents of the <code>uniq.test</code> file and outputs a copy of the repeated lines.</p>

EXAMPLE 1 Using the unq command (Continued)

```
example% cat unq.test
This is a test.
This is a test.
TEST.
Computer.
TEST.
TEST.
Software.

example% unq -d unq.test
This is a test.
TEST.
example%
```

The next example outputs just those lines that are not repeated in the unq.test file.

```
example% unq -u unq.test
TEST.
Computer.
Software.
example%
```

The last example outputs a report with each line preceded by a count of the number of times each line occurred in the file:

```
example% unq -c unq.test
 2 This is a test.
 1 TEST.
 1 Computer.
 2 TEST.
 1 Software.
example%
```

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of unq: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

```
0          Successful completion.
>0        An error occurred.
```

NAME	units – converts quantities expressed in standard scales to other scales
SYNOPSIS	units
DESCRIPTION	<p>units converts quantities expressed in various standard scales to their equivalents in other scales. It works interactively in this fashion:</p> <pre>You have:~~inch You want:~~cm * 2.540000e+00 / 3.937008e-01</pre> <p>A quantity is specified as a multiplicative combination of units optionally preceded by a numeric multiplier. Powers are indicated by suffixed positive integers, division by the usual sign:</p> <pre>You have:~~15 lbs force/in2 You want:~~atm * 1.020689e+00 / 9.797299e-01</pre> <p>units only does multiplicative scale changes; thus it can convert Kelvin to Rankine, but not Celsius to Fahrenheit. Most familiar units, abbreviations, and metric prefixes are recognized, together with a generous leavening of exotica and a few constants of nature including:</p> <pre>pi ratio of circumference to diameter, c speed of light, e charge on an electron, g acceleration of gravity, force same as g, mole Avogadro's number, water pressure head per unit height of water, au astronomical unit.</pre> <p>Pound is not recognized as a unit of mass; lb is. Compound names are run together, (for example, lightyear). British units that differ from their U.S. counterparts are prefixed thus: brgallon. For a complete list of units, type:</p> <pre>cat /usr/share/lib/unittab</pre>
FILES	/usr/share/lib/unittab

NAME | unix2dos – convert text file from ISO format to DOS format

SYNOPSIS | **unix2dos** [-ascii] [-iso] [-7] [-437 | -850 | -860 | -863
| -865] *originalfile* *convertedfile*

DESCRIPTION | The unix2dos utility converts ISO standard characters to the corresponding characters in the DOS extended character set.

| This command may be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.

| If the original file and the converted file are the same, unix2dos will rewrite the original file after converting it.

OPTIONS | The following options are supported:

| -ascii | Adds carriage returns and converts end of file characters in SunOS format text files to conform to DOS requirements.

| -iso | This is the default. Converts ISO standard characters to the corresponding character in the DOS extended character set.

| -7 | Converts 8 bit SunOS characters to 7 bit DOS characters.

| On non-i386 systems, unix2dos will attempt to obtain the keyboard type to determine which code page to use. Otherwise, the default is US. The user may override the code page with one of the following options:

| -437 | Use US code page

| -850 | Use multilingual code page

| -860 | Use Portuguese code page

| -863 | Use French Canadian code page

| -865 | Use Danish code page

OPERANDS | The following operands are required:

| *originalfile* | The original file in ISO format that is being converted to DOS format.

| *convertedfile* | The new file in DOS format that has been converted from the original ISO file format.

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

DIAGNOSTICS

File *filename* not found, or no read permission

The input file you specified does not exist, or you do not have read permission. Check with the SunOS command, `ls -l` (see `ls(1)`).

Bad output filename *filename*, or no write permission

The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive or diskette is not write-protected.

Error while writing to temporary file

An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the `DIR` command. Also be certain that the default diskette or drive is write-enabled (not write-protected). Notice that when this error occurs, the original file remains intact.

Translated tmpfile name = *filename*.

Could not rename tmpfile to *filename*.

The program could not perform the final step in converting your file. Your converted file is stored under the name indicated on the second line of this message.

NAME	uptime – show how long the system has been up				
SYNOPSIS	uptime				
DESCRIPTION	The <code>uptime</code> command prints the current time, the length of time the system has been up, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. It is, essentially, the first line of a <code>w(1)</code> command.				
EXAMPLES	Below is an example of the output <code>uptime</code> provides: <pre>example% uptime 10:47am up 27 day(s), 50 mins, 1 user, load average: 0.18, 0.26, 0.20</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>w(1)</code> , <code>who(1)</code> , <code>whodo(1M)</code> , <code>attributes(5)</code>				
NOTES	<code>who -b</code> gives the time the system was last booted.				

users(1B)

NAME users – display a compact list of users logged in

SYNOPSIS /usr/ucb/users [*filename*]

DESCRIPTION The users utility lists the login names of the users currently on the system in a compact, one-line format.

Specifying *filename* tells users where to find its information; by default it checks /var/adm/utmpx.

Typing users is equivalent to typing who -q.

EXAMPLES **EXAMPLE 1** Listing current users

```
example% users
paul george ringoexample%
```

FILES /var/adm/utmpx

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO who(1), attributes(5)

NAME	uucp, uulog, uuname – UNIX-to-UNIX system copy
SYNOPSIS	<pre> uucp [-c -C] [-d -f] [-ggrade] [-jmr] [-nuser] [-sfile] [-xdebug_level] source-file destination-file uulog [-ssys] [-fsystem] [-x] [-number] system uuname [-c -l] </pre>
uucp	The uucp utility copies files named by the <i>source-file</i> arguments to the <i>destination-file</i> argument.
uulog	The uulog utility queries a log file of uucp or uuxqt transactions in file <i>/var/uucp/.Log/uucico/system</i> or <i>/var/uucp/.Log/uuxqt/system</i> .
uuname	The uuname utility lists the names of systems known to uucp.
uucp	<p>The following options are supported by uucp:</p> <ul style="list-style-type: none"> -c Does not copy local file to the spool directory for transfer to the remote machine (default). -C Forces the copy of local files to the spool directory for transfer. -d Makes all necessary directories for the file copy (default). -f Does not make intermediate directories for the file copy. -g <i>grade</i> <i>grade</i> can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The <code>uuglist</code> command can determine whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the <code>uuglist</code> command will be a list of service grades that are available, or a message that says to use a single letter or number as a grade of service. -j Prints the uucp job identification string on standard output. This job identification can be used by <code>uustat</code> to obtain the status of a uucp job or to terminate a uucp job. The uucp job is valid as long as the job remains queued on the local system. -m Sends mail to the requester when the copy is complete. -n <i>user</i> Notifies <i>user</i> on the remote system that a file was sent. -r Does not start the file transfer, just queue the job. -s <i>file</i> Reports status of the transfer to <i>file</i>. This option is accepted for compatibility, but it is ignored because it is insecure. -x <i>debug_level</i> Produce debugging output on standard output. <i>debug_level</i> is a number between 0 and 9. As <i>debug_level</i> increases to 9, more detailed debugging information is given. This option may not be available on all systems.

uucp(1C)

uulog	<p>The following options cause <code>uulog</code> to print logging information:</p> <p><code>-s sys</code> Prints information about file transfer work involving system <i>sys</i>.</p> <p><code>-f system</code> Executes a <code>tail -f</code> command of the file transfer log for <i>system</i>. You must press <code>BREAK</code> to exit this function.</p> <p>Other options used in conjunction with the above options are:</p> <p><code>-x</code> Looks in the <code>uuxqt</code> log file for the given system.</p> <p><code>-number</code> Executes a <code>tail</code> command of <i>number</i> lines.</p>
uuname	<p>The following options are supported by <code>uuname</code>:</p> <p><code>-c</code> Displays the names of systems known to <code>cu</code>. The two lists are the same, unless your machine is using different <code>Systems</code> files for <code>cu</code> and <code>uucp</code>. See the <code>Sysfiles</code> file.</p> <p><code>-l</code> Displays the local system name.</p>
OPERANDS	<p>The source file name may be a path name on your machine, or may have the form:</p> <p><code>system-name!pathname</code></p> <p>where <i>system-name</i> is taken from a list of system names that <code>uucp</code> knows about. <i>source_file</i> is restricted to no more than one <i>system-name</i>. The destination <i>system-name</i> may also include a list of system names such as</p> <p><code>system-name!system-name!...!system-name!pathname</code></p> <p>In this case, an attempt is made to send the file, using the specified route, to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information (see <code>NOTES</code> below for restrictions).</p> <p>For C-Shell users, the exclamation point (!) character must be surrounded by single quotes ('), or preceded by a backslash (\).</p> <p>The shell metacharacters <code>?</code>, <code>*</code> and <code>[...]</code> appearing in <i>pathname</i> will be expanded on the appropriate system.</p> <p>Pathnames may be one of the following:</p> <ol style="list-style-type: none">1. An absolute pathname.2. A pathname preceded by <code>~user</code> where <i>user</i> is a login name on the specified system and is replaced by that user's login directory.3. A pathname preceded by <code>~/destination</code> where <i>destination</i> is appended to <code>/var/spool/uucppublic</code>. (Note: This destination will be treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that the destination is a directory, follow it with a forward slash (/). For example, <code>~/dan/</code> as the destination will create the directory <code>/var/spool/uucppublic/dan</code> if it does not exist and put the requested file(s) in

that directory).

Anything else is prefixed by the current directory.

If the result is an erroneous path name for the remote system, the copy will fail. If the *destination-file* is a directory, the last part of the *source-file* name is used.

Invoking uucp with shell wildcard characters as the remote *source-file* invokes the uux(1C) command to execute the uucp command on the remote machine. The remote uucp command spools the files on the remote machine. After the first session terminates, if the remote machine is configured to transfer the spooled files to the local machine, the remote machine will initiate a call and send the files; otherwise, the user must "call" the remote machine to transfer the files from the spool directory to the local machine. This call can be done manually using Uutry(1M), or as a side effect of another uux(1C) or uucp call.

Notice that the local machine must have permission to execute the uucp command on the remote machine in order for the remote machine to send the spooled files.

uucp removes execute permissions across the transmission and gives 0666 read and write permissions (see chmod(2)).

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of uucp: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_TIME, NLSPATH, and TZ.

EXIT STATUS

The following exit values are returned:

0 Successful completion.
>0 An error occurred.

uucp(1C)

NOTES For security reasons, the domain of remotely accessible files may be severely restricted. You will probably not be able to access files by path name; ask a responsible person on the remote system to send them to you. For the same reasons you will probably not be able to send files to arbitrary path names. As distributed, the remotely accessible files are those whose names begin `/var/spool/uucppublic` (equivalent to `~/`).

All files received by `uucp` will be owned by `uucp`.

The `-m` option will only work when sending files or receiving a single file. Receiving multiple files specified by special shell characters `?`, `&`, and `[. . .]` will not activate the `-m` option.

The forwarding of files through other systems may not be compatible with the previous version of `uucp`. If forwarding is used, all systems in the route must have compatible versions of `uucp`.

Protected files and files that are in protected directories that are owned by the requester can be sent by `uucp`. However, if the requester is `root`, and the directory is not searchable by "other" or the file is not readable by "other", the request will fail.

Strings that are passed to remote systems may not be evaluated in the same locale as the one in use by the process that invoked `uucp` on the local system.

Configuration files must be treated as C (or POSIX) locale text files.

NAME	uuencode, uudecode – encode a binary file, or decode its encoded representation
SYNOPSIS	uuencode [<i>source-file</i>] <i>decode_pathname</i> uudecode [-p] [<i>encoded-file</i>]
DESCRIPTION	These commands encode and decode files as follows:
uuencode	The uuencode utility converts a binary file into an encoded representation that can be sent using mail(1). It encodes the contents of <i>source-file</i> , or the standard input if no <i>source-file</i> argument is given. The <i>decode_pathname</i> argument is required. The <i>decode_pathname</i> is included in the encoded file's header as the name of the file into which uudecode is to place the binary (decoded) data. uuencode also includes the permission modes of <i>source-file</i> (except setuid, setgid, and sticky-bits), so that <i>decode_pathname</i> is recreated with those same permission modes.
uudecode	The uudecode utility reads an <i>encoded-file</i> , strips off any leading and trailing lines added by mailer programs, and recreates the original binary data with the filename and the mode specified in the header. The encoded file is an ordinary portable character set text file; it can be edited by any text editor. It is best only to change the mode or <i>decode_pathname</i> in the header to avoid corrupting the decoded binary.
OPTIONS	The following option is supported:
uudecode	-p Decodes <i>encoded-file</i> and sends it to standard output. This allows uudecode to be used in a pipeline.
OPERANDS	The following operands are supported by uuencode and uudecode:
uuencode	<i>decode_pathname</i> The pathname of the file into which the uudecode utility will place the decoded file. If there are characters in <i>decode_pathname</i> that are not in the portable filename character set the results are unspecified.
	<i>source-file</i> A pathname of the file to be encoded.
uudecode	<i>encoded-file</i> The pathname of a file containing the output of uuencode.
USAGE	See largefile(5) for the description of the behavior of uuencode and uudecode when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of uuencode and uudecode: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.
OUTPUT	stdout The standard output is a text file (encoded in the character set of the current locale) that begins with the line:

uuencode(1C)

```
"begin%s%s%\n", <mode>, decode_pathname
```

and ends with the line:

```
end\n
```

In both cases, the lines have no preceding or trailing blank characters.

The algorithm that is used for lines in between `begin` and `end` takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets are converted to characters by adding a value of `0x20` to each octet, so that each octet is in the range `0x20–0x5f`, and then it is assumed to represent a printable character. It then will be translated into the corresponding character codes for the codeset in use in the current locale. (For example, the octet `0x41`, representing `A`, would be translated to `A` in the current codeset, such as `0xc1` if it were EBCDIC.)

Where the bits of two octets are combined, the least significant bits of the first octet are shifted left and combined with the most significant bits of the second octet shifted right. Thus, the three octets `A`, `B`, `C` are converted into the four octets:

```
0x20 + (( A >> 2                                     ) & 0x3F)
0x20 + (((A << 4) ((B >> 4) & 0xF) & 0x3F)
0x20 + (((B << 2) ((C >> 6) & 0x3) & 0x3F)
0x20 + (( C                                     ) & 0x3F)
```

These octets are then translated into the local character set.

Each encoded line contains a length character, equal to the number of characters to be decoded plus `0x20` translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line is 45.

EXIT STATUS The following exit values are returned:

```
0          Successful completion.
>0        An error occurred.
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Standard

SEE ALSO `mail(1)`, `mailx(1)`, `uucp(1C)`, `uux(1C)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

- NOTES** | The encoded file's size is expanded by 35% (3 bytes become 4, plus control information), causing it to take longer to transmit than the equivalent binary.
- The user on the remote system who is invoking `uudecode` (typically `uucp`) must have write permission on the file specified in the *decode_pathname*.
- If you invoke `uuencode` and then execute `uudecode` on a file in the same directory, you will overwrite the original file.

uuglist(1C)

NAME | uuglist – print the list of service grades that are available on this UNIX system

SYNOPSIS | **uuglist** [-u]

DESCRIPTION | uuglist prints the list of service grades that are available on the system to use with the -g option of uucp(1C) and uux(1C).

OPTIONS | -u List the names of the service grades that the user is allowed to use with the -g option of the uucp and uux commands.

FILES | /etc/uucp/Grades contains the list of service grades

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

SEE ALSO | uucp(1C), uux(1C), attributes(5)

NAME	uustat – uucp status inquiry and job control
SYNOPSIS	<pre> uustat [[-m] [-p] [-q] [-k <i>jobid</i> [-n]] [-r <i>jobid</i> [-n]]] uustat [-a] [-s <i>system</i> [-j]] [-u <i>user</i>] [-S <i>qric</i>] uustat -t <i>system</i> [-c] [-d <i>number</i>] </pre>
DESCRIPTION	<p>The uustat utility functions in the following three areas:</p> <ol style="list-style-type: none"> 1. Displays the general status of, or cancels, previously specified uucp commands. 2. Provides remote system performance information, in terms of average transfer rates or average queue times. 3. Provides general remote system-specific and user-specific status of uucp connections to other systems.
OPTIONS	The following options are supported:
General Status	<p>These options obtain general status of, or cancel, previously specified uucp commands:</p> <ul style="list-style-type: none"> -a Lists all jobs in queue. -j Lists the total number of jobs displayed. The -j option can be used in conjunction with the -a or the -s option. -k<i>jobid</i> Kills the uucp request whose job identification is <i>jobid</i>. The killed uucp request must belong to the user issuing the uustat command unless the user is the super-user or uucp administrator. If the job is killed by the super-user or uucp administrator, electronic mail is sent to the user. -m Reports the status of accessibility of all machines. -n Suppresses all standard output, but not standard error. The -n option is used in conjunction with the -k and -r options. -p Executes the command <code>ps -flp</code> for all the process-ids that are in the lock files. -q Lists the jobs queued for each machine. If a status file exists for the machine, its date, time and status information are reported. In addition, if a number appears in parentheses next to the number of C or X files, it is the age in days of the oldest C./X. file for that system. The <code>Retry</code> field represents the number of hours until the next possible call. The <code>Count</code> is the number of failure attempts. <i>Note:</i> For systems with a moderate number of outstanding jobs, this could take 30 seconds or more of real-time to execute. An example of the output produced by the -q option is: <pre> eagle 3C 04/07-11:07 NO DEVICES AVAILABLE mh3bs3 2C 07/07-10:42 SUCCESSFUL </pre>

uustat(1C)

	<p>This indicates the number of command files that are waiting for each system. Each command file may have zero or more files to be sent (zero means to call the system and see if work is to be done). The date and time refer to the previous interaction with the system followed by the status of the interaction.</p>
	<p><i>-rjobid</i> Rejuvenates <i>jobid</i>. The files associated with <i>jobid</i> are touched so that their modification time is set to the current time. This prevents the cleanup daemon from deleting the job until the jobs' modification time reaches the limit imposed by the daemon.</p>
Remote System Status	<p>These options provide remote system performance information, in terms of average transfer rates or average queue times. The <i>-c</i> and <i>-d</i> options can only be used in conjunction with the <i>-t</i> option:</p>
	<p><i>-t</i><i>system</i> Reports the average transfer rate or average queue time for the past 60 minutes for the remote <i>system</i>. The following parameters can only be used with this option:</p>
	<p><i>-c</i> Average queue time is calculated when the <i>-c</i> parameter is specified and average transfer rate when <i>-c</i> is not specified. For example, the command:</p> <pre>example% uustat -teagle -d50 -c</pre> <p>produces output in the following format:</p> <pre>average queue time to eagle for last 50 minutes: 5 seconds</pre> <p>The same command without the <i>-c</i> parameter produces output in the following format:</p> <pre>average transfer rate with eagle for last 50 minutes: 2000.88 bytes/sec</pre>
	<p><i>-d</i><i>number</i> <i>number</i> is specified in minutes. Used to override the 60 minute default used for calculations. These calculations are based on information contained in the optional performance log and therefore may not be available. Calculations can only be made from the time that the performance log was last cleaned up.</p>
User- or System-Specific Status	<p>These options provide general remote system-specific and user-specific status of uucp connections to other systems. Either or both of the following options can be specified with <i>uustat</i>. The <i>-j</i> option can be used in conjunction with the <i>-s</i> option to list the total number of jobs displayed:</p>
	<p><i>-ssystem</i> Reports the status of all uucp requests for remote system <i>system</i>.</p>
	<p><i>-uuser</i> Reports the status of all uucp requests issued by <i>user</i>.</p>
	<p>Output for both the <i>-s</i> and <i>-u</i> options has the following format:</p> <pre>eagleN1bd7 4/07-11:07 S eagle dan 522 /home/dan/A eagleC1bd8 4/07-11:07 S eagle dan 59 D.3b2a12ce4924</pre>

```
4/07-11:07      S      eagle  dan      rmail  mike
```

With the above two options, the first field is the *jobid* of the job. This is followed by the date/time. The next field is an S if the job is sending a file or an R if the job is requesting a file. The next field is the machine where the file is to be transferred. This is followed by the user-id of the user who queued the job. The next field contains the size of the file, or in the case of a remote execution (*rmail* is the command used for remote mail), the name of the command. When the size appears in this field, the file name is also given. This can either be the name given by the user or an internal name (for example, D.3b2a1ce4924) that is created for data files associated with remote executions (*rmail* in this example).

-Sqrlic Reports the job state:

q	for queued jobs
r	for running jobs
i	for interrupted jobs
c	for completed jobs

A job is queued if the transfer has not started. A job is running when the transfer has begun. A job is interrupted if the transfer began but was terminated before the file was completely transferred. A completed job is a job that successfully transferred. The completed state information is maintained in the accounting log, which is optional and therefore may be unavailable. The parameters can be used in any combination, but at least one parameter must be specified. The *-S* option can also be used with *-s* and *-u* options. The output for this option is exactly like the output for *-s* and *-u* except that the job states are appended as the last output word. Output for a completed job has the following format:

```
eagleC1bd3 completed
```

When no options are given, *uustat* writes to standard output the status of all *uucp* requests issued by the current user.

ENVIRONMENT VARIABLES

See *environ(5)* for descriptions of the following environment variables that affect the execution of *uustat*: *LANG*, *LC_ALL*, *LC_COLLATE*, *LC_CTYPE*, *LC_MESSAGES*, *LC_TIME*, *NLSPATH*, and *TZ*.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

FILES

<i>/var/spool/uucp/*</i>	spool directories
<i>/var/uucp/.Admin/account</i>	accounting log
<i>/var/uucp/.Admin/perflog</i>	performance log

uustat(1C)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu
Interface Stability	Standard

SEE ALSO `uucp(1C)`, `attributes(5)`, `environ(5)`, `standards(5)`

DIAGNOSTICS The `-t` option produces no message when the data needed for the calculations is not being recorded.

NOTES After the user has issued the `uucp` request, if the file to be transferred is moved, deleted or was not copied to the spool directory (`-C` option) when the `uucp` request was made, `uustat` reports a file size of `-99999`. This job will eventually fail because the file(s) to be transferred can not be found.

NAME	uuto, uupick – public UNIX-to-UNIX system file copy																
SYNOPSIS	uuto [-mp] <i>source-file... destination</i> uupick [-s <i>system</i>]																
uuto	<p>uuto sends <i>source-file</i> to <i>destination</i>. uuto uses the uucp(1C) facility to send files, while it allows the local system to control the file access. A source-file name is a path name on your machine. Destination has the form:</p> <pre>system[!<i>system</i>] ... !<i>user</i></pre> <p>where <i>system</i> is taken from a list of system names that uucp knows about. <i>User</i> is the login name of someone on the specified system.</p> <p>The files (or sub-trees if directories are specified) are sent to PUBDIR on <i>system</i>, where PUBDIR is a public directory defined in the uucp source. By default, this directory is <code>/var/spool/uucppublic</code>. Specifically the files are sent to <code>PUBDIR/receive/user/mysystem/files</code>.</p> <p>The recipient is notified by mail(1) of the arrival of files.</p>																
uupick	<p>uupick accepts or rejects the files transmitted to the user. Specifically, uupick searches PUBDIR for files destined for the user. For each entry (file or directory) found, the following message is printed on standard output:</p> <pre>from system <i>sysname</i>: [file <i>file-name</i>] [dir <i>dirname</i>] ?</pre> <p>uupick then reads a line from standard input to determine the disposition of the file:</p> <table border="0"> <tr> <td><new-line></td> <td>Go to next entry.</td> </tr> <tr> <td>d</td> <td>Delete the entry.</td> </tr> <tr> <td>m [<i>dir</i>]</td> <td>Move the entry to named directory <i>dir</i>. If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.</td> </tr> <tr> <td>a [<i>dir</i>]</td> <td>Same as m above, except it moves all the files sent from <i>system</i>.</td> </tr> <tr> <td>p</td> <td>Print the content of the file.</td> </tr> <tr> <td>q</td> <td>Stop.</td> </tr> <tr> <td>EOT (control-d)</td> <td>Same as q.</td> </tr> <tr> <td>!command</td> <td>Escape to the shell to do <i>command</i>.</td> </tr> </table>	<new-line>	Go to next entry.	d	Delete the entry.	m [<i>dir</i>]	Move the entry to named directory <i>dir</i> . If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.	a [<i>dir</i>]	Same as m above, except it moves all the files sent from <i>system</i> .	p	Print the content of the file.	q	Stop.	EOT (control-d)	Same as q.	!command	Escape to the shell to do <i>command</i> .
<new-line>	Go to next entry.																
d	Delete the entry.																
m [<i>dir</i>]	Move the entry to named directory <i>dir</i> . If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.																
a [<i>dir</i>]	Same as m above, except it moves all the files sent from <i>system</i> .																
p	Print the content of the file.																
q	Stop.																
EOT (control-d)	Same as q.																
!command	Escape to the shell to do <i>command</i> .																

uuto(1C)

	<p>* Print a command summary.</p>				
uuto	<p>The following options are supported by <code>uuto</code>:</p> <ul style="list-style-type: none"><code>-m</code> Send mail to the sender when the copy is complete.<code>-p</code> Copy the source file into the spool directory before transmission.				
uupick	<p>The following option is supported by <code>uupick</code>:</p> <ul style="list-style-type: none"><code>-s system</code> Search only the PUBDIR for files sent from <code>system</code>.				
OPERANDS	<p>The following operands are supported for <code>uuto</code>:</p> <p><i>destination</i> A string of the form:</p> <p style="text-align: center;"><i>system-name ! user</i></p> <p>where <i>system-name</i> is taken from a list of system names that <code>uucp</code> knows about; see <code>uname</code>. The argument <i>user</i> is the login name of someone on the specified system. The destination <i>system-name</i> can also be a list of names such as</p> <p style="text-align: center;"><i>system-name ! system-name ! ... ! system-name ! user</i></p> <p>in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.</p> <p><i>source-file</i> A pathname of a file on the local system to be copied to <i>destination</i>.</p>				
ENVIRONMENT VARIABLES	<p>See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>uuto</code> and <code>uupick</code>: <code>LC_TYPE</code>, <code>LC_MESSAGES</code>, and <code>NLSPATH</code>.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none">0 Successful completion.>0 An error occurred.				
FILES	<p><code>PUBDIR</code> <code>/var/spool/uucppublic</code> public directory</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWbnuu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbnuu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWbnuu				
SEE ALSO	<p><code>mail(1)</code>, <code>uucp(1C)</code>, <code>uustat(1C)</code>, <code>uux(1C)</code>, <code>uucleanup(1M)</code>, <code>attributes(5)</code></p>				

NOTES In order to send files that begin with a dot (for instance, `.profile`), the files must be qualified with a dot. For example, the following files are correct:

```
.profile .prof* .profil?
```

The following files are incorrect:

```
*prof* ?profile
```

uux(1C)

NAME	<code>uux</code> – UNIX-to-UNIX system command execution
SYNOPSIS	<code>uux</code> [-] [-bcCjnprz] [-a <i>name</i>] [-g <i>grade</i>] [-s <i>filename</i>] [-x <i>debug_level</i>] <i>command-string</i>
DESCRIPTION	<p>The <code>uux</code> utility will gather zero or more files from various systems, execute a command on a specified system and then send standard output to a file on a specified system.</p> <p><i>Note:</i> For security reasons, most installations limit the list of commands executable on behalf of an incoming request from <code>uux</code>, permitting only the receipt of mail (see <code>mail(1)</code>). (Remote execution permissions are defined in <code>/etc/uucp/Permissions</code>.)</p> <p>The <i>command-string</i> is made up of one or more arguments that look like a shell command line, except that the command and file names may be prefixed by <i>system-name</i>!. A null <i>system-name</i> is interpreted as the local system.</p> <p>File names may be one of the following:</p> <ul style="list-style-type: none">■ An absolute path name.■ A path name preceded by <code>~xxx</code>, where <code>xxx</code> is a login name on the specified system and is replaced by that user's login directory. <p>Anything else is prefixed by the current directory.</p> <p>As an example, the command:</p> <pre>example% uux "!diff sys1!/home/dan/filename1 \ sys2!/a4/dan/filename2 > !~/dan/filename.diff"</pre> <p>will get the <code>filename1</code> and <code>filename2</code> files from the <code>sys1</code> and <code>sys2</code> machines, execute a <code>diff(1)</code> command and put the results in <code>filename.diff</code> in the local <code>PUBDIR/dan/</code> directory. <code>PUBDIR</code> is a public directory defined in the <code>uucp</code> source. By default, this directory is <code>/var/spool/uucppublic</code>.</p> <p>Any special shell characters (such as <code><</code> <code>></code> <code>;</code> <code> </code>) should be quoted either by quoting the entire <i>command-string</i>, or quoting the special characters as individual arguments. The redirection operators <code>>></code>, <code><<</code>, <code>> </code>, and <code>>&</code> cannot be used.</p> <p><code>uux</code> will attempt to get all appropriate files to the specified system where they will be processed. For files that are output files, the file name must be escaped using parentheses. For example, the command:</p> <pre>example% uux "a!cut -f1 b!/usr/filename > c!/usr/filename"</pre> <p>gets <code>/usr/filename</code> from system <code>b</code> and sends it to system <code>a</code>, performs a <code>cut</code> command on that file and sends the result of the <code>cut</code> command to system <code>c</code>.</p> <p><code>uux</code> will notify you if the requested command on the remote system was disallowed. This notification can be turned off by the <code>-n</code> option. The response comes by remote mail from the remote machine.</p>

OPTIONS	The following options are supported:
-	The standard input to <code>uux</code> is made the standard input to the <i>command-string</i> .
-a <i>name</i>	Uses <i>name</i> as the user job identification replacing the initiator user-id. (Notification will be returned to user-id <i>name</i> .)
-b	Returns whatever standard input was provided to the <code>uux</code> command if the exit status is non-zero.
-c	Does not copy local file to the spool directory for transfer to the remote machine (default).
-C	Forces the copy of local files to the spool directory for transfer.
-g <i>grade</i>	<i>grade</i> can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The <code>uuglist(1C)</code> command determines whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the <code>uuglist</code> command will be a list of service grades that are available or a message that says to use a single letter or number as a grade of service.
-j	Outputs the jobid string on the standard output which is the job identification. This job identification can be used by <code>uustat(1C)</code> to obtain the status or terminate a job.
-n	Does not notify the user if the command fails.
-p	Same as -. The standard input to <code>uux</code> is made the standard input to the <i>command-string</i> .
-r	Does not start the file transfer, but just queues the job.
-s <i>filename</i>	Reports status of the transfer in <i>filename</i> . This option is accepted for compatibility, but it is ignored because it is insecure.
-x <i>debug_level</i>	Produces debugging output on the standard output. <i>debug_level</i> is a number between 0 and 9. As <i>debug_level</i> increases to 9, more detailed debugging information is given.
-z	Sends success notification to the user.
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>uux</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	The following exit values are returned:
0	Successful completion.
>0	An error occurred.
FILES	<code>/etc/uucp/*</code> other data and programs

uux(1C)

/etc/uucp/Permissions	remote execution permissions
/usr/lib/uucp/*	other programs
/var/spool/uucp	spool directories

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu
Interface Stability	Standard

SEE ALSO `cut(1)`, `mail(1)`, `uucp(1C)`, `uuglist(1C)`, `uustat(1C)`, `attributes(5)`, `environ(5)`, `standards(5)`

NOTES The execution of commands on remote systems takes place in an execution directory known to the uucp system.

All files required for the execution will be put into this directory unless they already reside on that machine. Therefore, the simple file name (without path or machine reference) must be unique within the uux request. The following command will NOT work:

```
example% uux "a!diff b!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

But the command:

```
example% uux "a!diff a!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

will work (if `diff` is a permitted command.)

Protected files and files that are in protected directories that are owned by the requester can be sent in commands using uux. However, if the requester is root, and the directory is not searchable by "other", the request will fail.

The following restrictions apply to the shell pipeline processed by uux:

- In gathering files from different systems, pathname expansion is not performed by uux. Thus, a request such as

```
uux "c89 remsys!~/*.c"
```

would attempt to copy the file named literally `*.c` to the local system.

- Only the first command of a shell pipeline may have a *system-name!*. All other commands are executed on the system of the first command.
- The use of the shell metacharacter `*` will probably not do what you want it to do.
- The shell tokens `<<` and `>>` are not implemented.
- The redirection operators `>>`, `<<`, `>|`, and `>&` cannot be used.

- The reserved word ! cannot be used at the head of the pipeline to modify the exit status.
- Alias substitution is not performed.

vacation(1)

NAME	vacation – reply to mail automatically
SYNOPSIS	vacation [-I] vacation [-a <i>alias</i>] [-f <i>database_file</i>] [-j] [-m <i>message_file</i>] [-s <i>sender</i>] [-tN] <i>username</i>
DESCRIPTION	The <code>vacation</code> utility automatically replies to incoming mail.
Installation	<p>The installation consists of an interactive program which sets up <code>vacation</code>'s basic configuration.</p> <p>To install <code>vacation</code>, type it with no arguments on the command line. The program creates a <code>.vacation.msg</code> file, which contains the message that is automatically sent to all senders when <code>vacation</code> is enabled, and starts an editor for you to modify the message. (See USAGE section.) Which editor is invoked is determined by the <code>VISUAL</code> or <code>EDITOR</code> environment variable, or <code>vi(1)</code> if neither of those environment variables are set.</p> <p>A <code>.forward</code> file is also created if one does not exist in your home directory. Once created, the <code>.forward</code> file will contain a line of the form:</p> <pre>\username, " /usr/bin/vacation username" One copy of an incoming message is sent to the username and another copy is piped into vacation.</pre> <p>If a <code>.forward</code> file is present in your home directory, it will ask whether you want to remove it, which disables <code>vacation</code> and ends the installation.</p> <p>The program automatically creates <code>.vacation.pag</code> and <code>.vacation.dir</code>, which contain a list of senders when <code>vacation</code> is enabled.</p>
Activation and Deactivation	The presence of the <code>.forward</code> file determines whether or not <code>vacation</code> is disabled or enabled. To disable <code>vacation</code> , remove the <code>.forward</code> file, or move it to a new name.
Initialization	The <code>-I</code> option clears the <code>vacation</code> log files, <code>.vacation.pag</code> and <code>.vacation.dir</code> , erasing the list of senders from a previous <code>vacation</code> session. (See OPTIONS section.)
Additional Configuration	<code>vacation</code> provides configuration options that are not part of the installation, these being <code>-a</code> , <code>-f</code> , <code>-j</code> , <code>-m</code> , <code>-s</code> , and <code>-t</code> . (See OPTIONS section.)
OPTIONS	<p>The following options are supported:</p> <p><code>-I</code> Initializes the <code>.vacation.pag</code> and <code>.vacation.dir</code> files and enables <code>vacation</code>. If the <code>-I</code> flag is not specified, and a <i>user</i> argument is given, <code>vacation</code> reads the first line from the standard input (for a <code>From:</code> line, no colon). If absent, it produces an error message.</p> <p>Options <code>-a</code>, <code>-f</code>, <code>-j</code>, <code>-m</code>, <code>-t</code>, and <code>-s</code> are configuration options to be used in conjunction with <code>vacation</code> in the <code>.forward</code> file, not on the command line. For example,</p>

`\username, "|/usr/bin/vacation -t1m username"` repeats replies to the sender every minute.

- `-a alias` Indicates that *alias* is one of the valid aliases for the user running *vacation*, so that mail addressed to that alias generates a reply.
- `-f file` Uses *file* instead of `.vacation` as the base name for the database file.
- `-j` Does not check whether the recipient appears in the `To:` or the `Cc:` line. Warning: use of this option can result in vacation replies being sent to mailing lists and other inappropriate places; its use is therefore strongly discouraged.
- `-m file` Uses *file* instead of `.vacation.msg` as the message to send for the reply.
- `-s sender` Replies to *sender* instead of the value read from the UNIX `From` line of the incoming message.
- `-tN` Changes the interval between repeat replies to the same sender. The default is 1 week. A trailing *s*, *m*, *h*, *d*, or *w* scales *N* to seconds, minutes, hours, days, or weeks, respectively.

Files `.vacation.msg` should include a header with at least a `Subject:` line (it should not include a `To:` line). For example:

```
Subject: I am on vacation
I am on vacation until July 22.  If you have something urgent,
please contact Joe Jones (jones@fb0).
--John
```

If the string `$$SUBJECT` appears in the `.vacation.msg` file, it is replaced with the subject of the original message when the reply is sent; thus, a `.vacation.msg` file such as

```
Subject: I am on vacation
I am on vacation until July 22.
Your mail regarding "$SUBJECT" will be read when I return.
If you have something urgent, please contact
Joe Jones (jones@fb0).
--John
```

will include the subject of the message in the reply.

No message is sent if the `To:` or the `Cc:` line does not list the user to whom the original message was sent or one of a number of aliases for them, if the initial `From` line includes the string `-REQUEST@`, or if a `Precedence: bulk` or `Precedence: junk` line is included in the header.

vacation will also not respond to mail from either `postmaster` or `Mailer-Daemon`.

vacation(1)

FILES ~/.forward
~/.vacation.msg

A list of senders is kept in the dbm format files `.vacation.pag` and `.vacation.dir` in your home directory. These files are dbm files and cannot be viewed directly with text editors.

NAME	vc – version control
SYNOPSIS	vc [-a] [-t] [-c <i>char</i>] [-s] [<i>keyword=value... keyword=value</i>]
DESCRIPTION	<p>This command is obsolete and will be removed in the next release.</p> <p>The <code>vc</code> command copies lines from the standard input to the standard output under control of its arguments and of “control statements” encountered in the standard input. In the process of performing the copy operation, user-declared <i>keywords</i> may be replaced by their string <i>value</i> when they appear in plain text and/or control statements.</p> <p>The copying of lines from the standard input to the standard output is conditional, based on tests (in control statements) of keyword values specified in control statements or as <code>vc</code> command arguments.</p> <p>A control statement is a single line beginning with a control character, except as modified by the <code>-t</code> keyletter (see below). The default control character is colon (:), except as modified by the <code>-c</code> keyletter (see below). Input lines beginning with a backslash (\) followed by a control character are not control lines and are copied to the standard output with the backslash removed. Lines beginning with a backslash followed by a non-control character are copied in their entirety.</p> <p>A keyword is composed of 9 or less alphanumeric; the first must be alphabetic. A value is any ASCII string that can be created with <code>ed</code>; a numeric value is an unsigned string of digits. Keyword values may not contain blanks or tabs.</p> <p>Replacement of keywords by values is done whenever a keyword surrounded by control characters is encountered on a version control statement. The <code>-a</code> keyletter (see below) forces replacement of keywords in all lines of text. An uninterpreted control character may be included in a value by preceding it with <code>\</code>. If a literal <code>\</code> is desired, then it too must be preceded by <code>\</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Forces replacement of keywords surrounded by control characters with their assigned value in all text lines and not just in <code>vc</code> statements. -t All characters from the beginning of a line up to and including the first tab character are ignored for the purpose of detecting a control statement. If a control statement is found, all characters up to and including the tab are discarded. -c<i>char</i> Specifies a control character to be used in place of the “:” default. -s Silences warning messages (not error) that are normally printed on the diagnostic output. <p><code>vc</code> recognizes the following version control statements:</p> <pre style="margin-left: 20px;">:dc1 <i>keyword</i>[, ..., <i>keyword</i>] Declare keywords. All keywords must be declared.</pre>

vc(1)

`:asg keyword=value`

Assign values to keywords. An `asg` statement overrides the assignment for the corresponding keyword on the `vc` command line and all previous `asg` statements for that keyword. Keywords that are declared but are not assigned values have null values.

`:if condition`

`...`

`:end`

Skip lines of the standard input. If the condition is true, all lines between the `if` statement and the matching `end` statement are copied to the standard output. If the condition is false, all intervening lines are discarded, including control statements. Note: Intervening `if` statements and matching `end` statements are recognized solely for the purpose of maintaining the proper `if`-`end` matching.

The syntax of a condition is:

<code><cond></code>	::= ["not"] <code><or></code>
<code><or></code>	::= <code><and></code> <code><and></code> " " <code><or></code>
<code><and></code>	::= <code><exp></code> <code><exp></code> "&" <code><and></code>
<code><exp></code>	::= " (" <code><or></code> ") " <code><value></code> <code><op></code> <code><value></code>
<code><op></code>	::= "=" "!=" "<" ">"
<code><value></code>	::= <code><arbitrary ASCII string></code> <code><numeric string></code>

The available operators and their meanings are:

<code>=</code>	equal
<code>!=</code>	not equal
<code>&</code>	and
<code> </code>	or
<code>></code>	greater than

< less than
 () used for logical groupings
 not may only occur immediately
 after the `if`, and when present,
 inverts the value of the entire
 condition

The `>` and `<` operate only on unsigned integer values (for example, `: 012 > 12` is false). All other operators take strings as arguments (for example, `: 012 != 12` is true).

The precedence of the operators (from highest to lowest) is:

= != > < all of equal precedence
 &
 |

Parentheses may be used to alter the order of precedence.

Values must be separated from operators or parentheses by at least one blank or tab.

`: :text`

Replace keywords on lines that are copied to the standard output. The two leading control characters are removed, and keywords surrounded by control characters in text are replaced by their value before the line is copied to the output file. This action is independent of the `-a` keyletter.

`:on`

`:off`

Turn on or off keyword replacement on all lines.

`:ctl char`

Change the control character to *char*.

`:msg message`

Print *message* on the diagnostic output.

`:err message`

Print *message* followed by:

```
ERROR: err statement on line ...
(915)
```

vc(1)

on the diagnostic output. vc halts execution, and returns an exit code of 1.

NAME	vgrind – grind nice program listings
SYNOPSIS	vgrind [-2fntwx] [-d <i>defs-file</i>] [-h <i>header</i>] [-l <i>language</i>] [-s <i>n</i>] [-o <i>pagelist</i>] [-P <i>printer</i>] [-T <i>output-device</i>] <i>filename...</i>
DESCRIPTION	<p>The vgrind utility formats the program sources named by the <i>filename</i> arguments in a nice style using troff(1). Comments are placed in italics, keywords in bold face, and as each function is encountered its name is listed on the page margin.</p> <p>vgrind runs in two basic modes, filter mode or regular mode. In filter mode, vgrind acts as a filter in a manner similar to tbl(1). The standard input is passed directly to the standard output except for lines bracketed by the troff-like macros:</p> <pre>.vS starts processing .vE ends processing</pre> <p>These lines are formatted as described above. The output from this filter can be passed to troff for output. There need be no particular ordering with eqn(1) or tbl(1).</p> <p>In regular mode, vgrind accepts input <i>filenames</i>, processes them, and passes them to troff for output. Use a hyphen ('-') to specify standard input; otherwise, vgrind will exit without attempting to read from the standard input. Filenames must be specified after all other option arguments.</p> <p>In regular mode, if the -t or -P option is specified, the output is:</p> <ul style="list-style-type: none"> ■ emitted (in troff format) to stdout if the -t option is specified. ■ printed (as PostScript) to the named printer if the -P option is specified. <p>Otherwise, the output is:</p> <ul style="list-style-type: none"> ■ printed (as PostScript) on the system default printer, if one is defined, and the command's stdout is a tty. ■ emitted (as PostScript) to stdout if it is not a tty (that is, if stdout is a pipe or a redirect to a file). <p>In both modes, vgrind passes any lines beginning with a decimal point without conversion.</p>
OPTIONS	<p>The following options are supported:</p> <pre>-2 Produces two-column output. Specifying this option changes the default point size to 8 (as if the -s8 option were supplied). It also arranges for output to appear in landscape mode. -f Forces filter mode. -n Does not make keywords boldface. -w Considers TAB characters to be spaced four columns apart instead of the usual eight.</pre>

vgrind(1)

- x Outputs the index file in a “pretty” format. The index file itself is produced whenever `vgrind` is run with a file called `index` that is present in the current directory. The index of function definitions can then be run off by giving `vgrind` the `-x` option and the file `index` as argument.
- d *defs-file* Specifies an alternate language definitions file (default is `/usr/lib/vgrindefs`).
- h *header* Specifies a header to appear in the center of every output page. Use quotes to specify headers with embedded spaces.
- l *language* Specifies the language to use. Among the *languages* currently known are: Bourne shell (`-lsh`), C (`-lc`, the default), C++ (`-lc++`), C shell (`-lcs`), emacs MLisp (`-lm1`), FORTRAN (`-lf`), Icon (`-lI`), ISP (`-i`), LDL (`-lLDL`), Model (`-lm`), Pascal (`-lp`), and RATFOR (`-lr`).
- P *printer* Sends output to the named *printer*.
- s *n* Specifies a point size to use on output (exactly the same as the argument of a `troff .ps` point size request).

`vgrind` passes the following options to the formatter specified by the `TROFF` environment variable. See ENVIRONMENT VARIABLES.

- t Similar to the same option in `troff`; that is, formatted text goes to the standard output.
- o *pagelist* Prints only those pages whose page numbers appear in the comma-separated *pagelist* of numbers and ranges. A range `N-M` means pages `N` through `M`; an initial `-N` means from the beginning to page `N`; and a final `N-` means from `N` to the end.
- T *output-device* Formats output for the specified *output-device*.

OPERANDS The following operand is supported:

- filename* Name of the program source to be processed by `vgrind`. Use `'-'` to specify the standard input.

ENVIRONMENT VARIABLES In regular mode, `vgrind` feeds its intermediate output to the text formatter given by the value of the `TROFF` environment variable, or to `/usr/bin/troff` if this variable is not defined in the environment. This mechanism allows for local variations in `troff`'s name.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

SEE ALSO `csh(1)`, `ctags(1)`, `eqn(1)`, `tbl(1)`, `troff(1)`, `attributes(5)`, `vgrindefs(5)`

BUGS `vgrind` assumes that a certain programming style is followed:

C	Function names can be preceded on a line only by SPACE, TAB, or an asterisk (*). The parenthesized arguments must also be on the same line.
FORTRAN	Function names need to appear on the same line as the keywords <code>function</code> or <code>subroutine</code> .
MLisp	Function names should not appear on the same line as the preceding <code>defun</code> .
Model	Function names need to appear on the same line as the keywords <code>is beginproc</code> .
Pascal	Function names need to appear on the same line as the keywords <code>function</code> or <code>procedure</code> .

If these conventions are not followed, the indexing and marginal function name comment mechanisms will fail.

More generally, arbitrary formatting styles for programs usually give unsightly results. To prepare a program for `vgrind` output, use TAB rather than SPACE characters to align source code properly, since `vgrind` uses variable width fonts.

The mechanism of `ctags(1)` in recognizing functions should be used here.

The `-w` option is annoying, but there is no other way to achieve the desired effect.

The macros defined in `tmac.vgrind` do not coexist gracefully with those of other macro packages, making filter mode difficult to use effectively.

`vgrind` does not process certain special characters in `csh(1)` scripts correctly.

vgrind(1)

The `tmac.vgrind` formatting macros wire in the page height and width used in two-column mode, effectively making two column output useless for paper sizes other than the standard American size of 8.5 inches by 11 inches. For other paper sizes, it is necessary to edit the size values given in `tmac.vgrind`. A better solution would be to create a `troff` output device specification intended specifically for landscape output and record size information there.

NAME	vi, view, vedit – screen-oriented (visual) display editor based on ex						
SYNOPSIS	<pre> /usr/bin/vi [- -s] [-l] [-L] [-R] [-r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command]filename... /usr/bin/view [- -s] [-l] [-L] [-R] [-r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command]filename... /usr/bin/vedit [- -s] [-l] [-L] [-R] [-r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command]filename... /usr/xpg4/bin/vi [- -s] [-l] [-L] [-R] [-r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command]filename... /usr/xpg4/bin/view [- -s] [-l] [-L] [-R] [-r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command]filename... /usr/xpg4/bin/vedit [- -s] [-l] [-L] [-R] [-r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command]filename... </pre>						
DESCRIPTION	<p>The vi (visual) utility is a display-oriented text editor based on an underlying line editor ex. It is possible to use the command mode of ex from within vi and to use the command mode of vi from within ex. The visual commands are described on this manual page; how to set options (like automatically numbering lines and automatically starting a new output line when you type carriage return) and all ex line editor commands are described on the ex(1) manual page.</p> <p>When using vi, changes you make to the file are reflected in what you see on your terminal screen. The position of the cursor on the screen indicates the position within the file.</p> <p>The view invocation is the same as vi except that the readonly flag is set.</p> <p>The vedit invocation is intended for beginners. It is the same as vi except that the report flag is set to 1, the showmode and novice flags are set, and magic is turned off. These defaults make it easier to learn how to use vi.</p>						
OPTIONS	The following options are supported:						
Invocation Options	The following invocation options are interpreted by vi (previously documented options are discussed under NOTES):						
	<table border="0"> <tr> <td style="vertical-align: top;">-l -s</td> <td>Suppresses all interactive user feedback. This is useful when processing editor scripts.</td> </tr> <tr> <td style="vertical-align: top;">-C</td> <td>Encryption option. Same as the -x option, except that vi simulates the C command of ex. The C command is like the X command of ex, except that all text read in is assumed to have been encrypted.</td> </tr> <tr> <td style="vertical-align: top;">-l</td> <td>Sets up for editing LISP programs.</td> </tr> </table>	-l -s	Suppresses all interactive user feedback. This is useful when processing editor scripts.	-C	Encryption option. Same as the -x option, except that vi simulates the C command of ex. The C command is like the X command of ex, except that all text read in is assumed to have been encrypted.	-l	Sets up for editing LISP programs.
-l -s	Suppresses all interactive user feedback. This is useful when processing editor scripts.						
-C	Encryption option. Same as the -x option, except that vi simulates the C command of ex. The C command is like the X command of ex, except that all text read in is assumed to have been encrypted.						
-l	Sets up for editing LISP programs.						

vi(1)

-L	Lists the name of all files saved as the result of an editor or system crash.
-r <i>filename</i>	Edits <i>filename</i> after an editor or system crash. (Recovers the version of <i>filename</i> that was in the buffer when the crash occurred.)
-R	Readonly mode. The <code>readonly</code> flag is set, preventing accidental overwriting of the file.
-S	This option is used in conjunction with the <code>-t tag</code> option to tell <code>vi</code> that the tags file may not be sorted and that, if the binary search (which relies on a sorted tags file) for <i>tag</i> fails to find it, the much slower linear search should also be done. Since the linear search is slow, users of large tags files should ensure that the tags files are sorted rather than use this flag. Creation of tags files normally produces sorted tags files. See <code>ctags(1)</code> for more information on tags files.
-t <i>tag</i>	Edits the file containing <i>tag</i> and position the editor at its definition.
-v	Starts up in display editing state, using <code>vi</code> . You can achieve the same effect by typing the <code>vi</code> command itself.
-V	Verbose. When <code>ex</code> commands are read by means of standard input, the input will be echoed to standard error. This may be useful when processing <code>ex</code> commands within shell scripts.
-wn	Sets the default window size to <i>n</i> . This is useful when using the editor over a slow speed line.
-x	Encryption option. When used, <code>vi</code> simulates the <code>x</code> command of <code>ex</code> and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the <code>crypt</code> command. The <code>X</code> command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the <code>-x</code> option. If an empty encryption key is entered (that is, if the return key is pressed right after the prompt), the file will not be encrypted. This is a good way to decrypt a file erroneously encrypted with a mistyped encryption key, such as a backspace or undo key.
+ <i>command</i> -c <i>command</i>	Begins editing by executing the specified editor <i>command</i> (usually a search or positioning command).

<code>/usr/xpg4/bin/vi</code>	If both the <code>-t tag</code> and the <code>-c command</code> options are given, the <code>-t tag</code> option will be processed first. That is, the file containing <code>tag</code> is selected by <code>-t</code> and then the command is executed.
OPERANDS	The following operands are supported:
	<i>filename</i> A file to be edited.
COMMAND SUMMARY vi Modes	The <code>vi</code> command modes are summarized in this section.
	Command Normal and initial mode. Other modes return to command mode upon completion. ESC (escape) is used to cancel a partial command.
	Input Entered by setting any of the following options:
	a A i I o O c C s S R
	Arbitrary text may then be entered. Input mode is normally terminated with the ESC character, or, abnormally, with an interrupt.
	Last line Reading input for <code>:</code> <code>/</code> <code>?</code> or <code>!</code> . Terminate by typing a carriage return. An interrupt cancels termination.
Sample commands	In the descriptions, CR stands for carriage return and ESC stands for the escape key.
	←
	→
	down-arrow
	up-arrow
	arrow keys move the cursor
	h j k l
	same as arrow keys
	<i>itext</i> ESC
	insert <i>text</i>
	<i>cwnew</i> ESC
	change word to <i>new</i>
	<i>eas</i> ESC
	pluralize word (end of word; append <i>s</i> ; escape from input state)
	x
	delete a character
	dw
	delete a word
	dd
	delete a line
	3dd
	delete 3 lines
	u
	undo previous change
	ZZ
	exit <code>vi</code> , saving changes
	:q!CR
	quit, discarding changes
	/ <i>text</i> CR
	search for <i>text</i>
	^U ^D
	scroll up or down

vi(1)

	<code>:cmdCR</code>	any ex or ed command
Counts before vi commands		Numbers may be typed as a prefix to some commands. They are interpreted in one of these ways:
	line/column number	<code>z G </code>
	scroll amount	<code>^D ^U</code>
	repeat effect	most of the rest
Interrupting, canceling	ESC	end insert or incomplete command
	DEL	(delete or rubout) interrupts
File manipulation	ZZ	if file modified, write and exit; otherwise, exit
	<code>:wCR</code>	write back changes
	<code>:w!CR</code>	forced write, if permission originally not valid
	<code>:qCR</code>	quit
	<code>:q!CR</code>	quit, discard changes
	<code>:e nameCR</code>	edit file <i>name</i>
	<code>:e!CR</code>	reedit, discard changes
	<code>:e + nameCR</code>	edit, starting at end
	<code>:e +nCR</code>	edit, starting at line <i>n</i>
	<code>:e #CR</code>	edit alternate file
	<code>:e! #CR</code>	edit alternate file, discard changes
	<code>:w nameCR</code>	write file <i>name</i>
	<code>:w! nameCR</code>	overwrite file <i>name</i>
	<code>:shCR</code>	run shell, then return
	<code>!:cmdCR</code>	run <i>cmd</i> , then return
	<code>:nCR</code>	edit next file in arglist
	<code>:n argsCR</code>	specify new arglist
	<code>^G</code>	show current file and line
	<code>:ta tagCR</code>	position cursor to <i>tag</i>
		In general, any ex or ed command (such as <i>substitute</i> or <i>global</i>) may be typed, preceded by a colon and followed by a carriage return.
Positioning within file	F	forward screen
	<code>^B</code>	backward screen

	<code>^D</code>	scroll down half screen
	<code>^U</code>	scroll up half screen
	<code>nG</code>	go to the beginning of the specified line (end default), where <i>n</i> is a line number
	<code>/pat</code>	next line matching <i>pat</i>
	<code>?pat</code>	previous line matching <i>pat</i>
	<code>n</code>	repeat last / or ? command
	<code>N</code>	reverse last / or ? command
	<code>/pat/+n</code>	<i>n</i> th line after <i>pat</i>
	<code>?pat?-n</code>	<i>n</i> th line before <i>pat</i>
	<code>]]</code>	next section/function
	<code>[[</code>	previous section/function
	<code>(</code>	beginning of sentence
	<code>)</code>	end of sentence
	<code>{</code>	beginning of paragraph
	<code>}</code>	end of paragraph
	<code>%</code>	find matching () or { }
Adjusting the screen	<code>^L</code>	clear and redraw window
	<code>^R</code>	clear and redraw window if ^L is → key
	<code>zCR</code>	redraw screen with current line at top of window
	<code>z-CR</code>	redraw screen with current line at bottom of window
	<code>z.CR</code>	redraw screen with current line at center of window
	<code>/pat/z-CR</code>	move <i>pat</i> line to bottom of window
	<code>zn.CR</code>	use <i>n</i> -line window
	<code>^E</code>	scroll window down one line
	<code>^Y</code>	scroll window up one line
	Marking and returning	<code>``</code>
<code>^^</code>		move cursor to first non-white space in line
<code>mx</code>		mark current position with the ASCII lower-case letter <i>x</i>
<code>`x</code>		move cursor to mark <i>x</i>
<code>ˆx</code>		move cursor to first non-white space in line marked by <i>x</i>

vi(1)

Line positioning	H	top line on screen	
	L	last line on screen	
	M	middle line on screen	
	+	next line, at first non-white space character	
	-	previous line, at first non-white space character	
	CR	return, same as +	
	down-arrow or j	next line, same column	
	up-arrow or k	previous line, same column	
	Character positioning	^	first non-white space character
		0	beginning of line
		\$	end of line
		l or →	forward
		h or ←	backward
		^H	same as ← (backspace)
space		same as → (space bar)	
fx		find next <i>x</i>	
Fx		find previous <i>x</i>	
tx		move to character following the next <i>x</i>	
Tx		move to character following the previous <i>x</i>	
;		repeat last f, F, t, or T	
,		repeat inverse of last f, F, t, or T	
n		move to column <i>n</i>	
%	find matching () or { }		
Words, sentences, paragraphs	w	forward a word	
	b	back a word	
	e	end of word	
)	to next sentence	
	}	to next paragraph	
	(back a sentence	
	{	back a paragraph	

Corrections during insert	W	forward a blank-delimited word
	B	back a blank-delimited word
	E	end of a blank-delimited word
	^H	erase last character (backspace)
	^W	erase last word
	erase	your erase character, same as ^H (backspace)
	kill	your kill character, erase this line of input
	\	quotes your erase and kill characters
	ESC	ends insertion, back to command mode
	CTRL-C	interrupt, suspends insert mode
	^D	backtab one character; reset left margin of <i>autoindent</i>
	^^D	caret (^) followed by control-d (^D); backtab to beginning of line; do not reset left margin of <i>autoindent</i>
	0^D	backtab to beginning of line; reset left margin of <i>autoindent</i>
	^V	quote non-printable character
Insert and replace	a	append after cursor
	A	append at end of line
	i	insert before cursor
	I	insert before first non-blank
	o	open line below
	O	open line above
	rx	replace single character with <i>x</i>
	R <i>text</i> ESC	replace characters
Operators	Operators are followed by a cursor motion and affect all text that would have been moved over. For example, since <i>w</i> moves over a word, <i>dw</i> deletes the word that would be moved over. Double the operator, for example <i>dd</i> , to affect whole lines.	
	d	delete
	c	change
	y	yank lines to buffer
	<	left shift
	>	right shift
	!	filter through command

vi(1)

Miscellaneous Operations	C	change rest of line (c\$)
	D	delete rest of line (d\$)
	s	substitute characters (c1)
	S	substitute lines (cc)
	J	join lines
	x	delete characters (d1)
	X	delete characters before cursor dh)
	Y	yank lines (yy)
Yank and Put	Put inserts the text most recently deleted or yanked; however, if a buffer is named (using the ASCII lower-case letters a - z), the text in that buffer is put instead.	
	3yy	yank 3 lines
	3yl	yank 3 characters
	p	put back text after cursor
	P	put back text before cursor
	"xp	put from buffer x
	"xy	yank to buffer x
	"xd	delete into buffer x
Undo, Redo, Retrieve	u	undo last change
	U	restore current line
	.	repeat last change
	"dp	retrieve d'th last delete
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>vi</code> and <code>view</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).	
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>vi</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_COLLATE</code> , <code>LC_CTYPE</code> , <code>LC_TIME</code> , <code>LC_MESSAGES</code> , <code>NLSPATH</code> , <code>PATH</code> , <code>SHELL</code> , and <code>TERM</code> .	
	<code>COLUMNS</code>	Override the system-selected horizontal screen size.
	<code>EXINIT</code>	Determine a list of <code>ex</code> commands that are executed on editor start-up, before reading the first file. The list can contain multiple commands by separating them using a vertical-line () character.
	<code>LINES</code>	Override the system-selected vertical screen size, used as the number of lines in a screenful and the vertical screen size in visual mode.

FILES /var/tmp default directory where temporary work files are placed; it can be changed using the `directory` option (see the `ex(1)` command)

/usr/share/lib/terminfo/?/* compiled terminal description database

/usr/lib/.COREterm/?/* subset of compiled terminal description database

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

Solaris Advanced User's Guide

AUTHOR `vi` and `ex` were developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.

NOTES Two options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see `intro(1)`). An `-r` option that is not followed with an option-argument has been replaced by `-L` and `+command` has been replaced by `-c` command.

The message file too large to recover with `-r` option, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the `-r` option will not be possible.

The editing environment defaults to certain configuration options. When an editing session is initiated, `vi` attempts to read the `EXINIT` environment variable. If it exists, the editor uses the values defined in `EXINIT`; otherwise the values set in `$HOME/.exrc` are used. If `$HOME/.exrc` does not exist, the default values are used.

vi(1)

To use a copy of `.exrc` located in the current directory other than `$HOME`, set the `exrc` option in `EXINIT` or `$HOME/.exrc`. Options set in `EXINIT` can be turned off in a local `.exrc` only if `exrc` is set in `EXINIT` or `$HOME/.exrc`.

Tampering with entries in `/usr/share/lib/terminfo/?/*` or `/usr/share/lib/terminfo/?/*` (for example, changing or removing an entry) can affect programs such as `vi` that expect the entry to be present and correct. In particular, removing the "dumb" terminal may cause unexpected problems.

Software tabs using `^T` work only immediately after the *autoindent*.

Left and right shifts on intelligent terminals do not make use of insert and delete character operations in the terminal.

The standard Solaris version of `vi` will be replaced by the POSIX.2-conforming version (see `standards(5)`) in the future. Scripts which use the `ex` family of addressing and features should use the `/usr/xpg4/bin` version of these utilities.

NAME vipw – edit the password file

SYNOPSIS /usr/ucb/vipw

DESCRIPTION vipw edits the password file while setting the appropriate locks, and does any necessary processing after the password file is unlocked. If the password file is already being edited, then you will be told to try again later. The vi(1) editor will be used unless the environment variable VISUAL or EDITOR indicates an alternate editor.

vipw performs a number of consistency checks on the password entry for root, and will not allow a password file with a “mangled” root entry to be installed. It also checks the /etc/shells file to verify the login shell for root.

FILES /etc/ptmp
/etc/shells

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO passwd(1), vi(1), passwd(4), attributes(5)

volcancel(1)

NAME | volcancel – cancel user’s request for removable media that is not currently in drive

SYNOPSIS | `/usr/lib/vold/volcancel [-n] [volume]`

DESCRIPTION | volcancel cancels a user’s request to access a particular floppy or CD-ROM file system. This command is useful when the removable media containing the file system is not currently in the drive.

| Use the path `/vol/rdisk/name_of_volume` to specify the volume. If called without a volume name to cancel, volcancel checks for Volume Management running.

OPTIONS | `-n` Display the nickname to the device name translation table.

EXAMPLES | **EXAMPLE 1** A sample of the volcancel command.

| To cancel a request to access an unnamed CD-ROM, use

| `example% /usr/lib/vold/volcancel vol/rdisk/unnamed_cdrom`

| To check if volume management is running, use:

| `example% /usr/lib/vold/volcancel || echo volmgmt not running`

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWvolu

SEE ALSO | rmmount(1M), volcheck(1), vold(1M), volmissing(1), rmmount.conf(4), vold.conf(4), attributes(5), volfs(7FS)

NAME	volcheck – checks for media in a drive and by default checks all floppy media				
SYNOPSIS	volcheck [-v] [-i <i>secs</i>] [-t <i>secs</i>] <i>pathname</i>				
DESCRIPTION	<p>The <code>volcheck</code> utility tells Volume Management to look at each <code>dev/<i>pathname</i></code> in sequence and determine if new media has been inserted in the drive.</p> <p>The default action is to <code>volcheck</code> all checkable media managed by volume management.</p>				
OPTIONS	<p>The following options are supported:</p> <p><code>-i <i>secs</i></code> Set the frequency of device checking to <i>secs</i> seconds. The default is 2 seconds. The minimum frequency is 1 second.</p> <p><code>-t <i>secs</i></code> Check the named device(s) for the next <i>secs</i> seconds. The maximum number of seconds allowed is 28800, which is 8 hours. The frequency of checking is specified by <code>-i</code>. There is no default total time.</p> <p><code>-v</code> Verbose.</p>				
OPERANDS	<p>The following operands are supported:</p> <p><i>pathname</i> The path name of a media device.</p>				
EXAMPLES	<p>EXAMPLE 1 A sample of the <code>volcheck</code> command.</p> <p>The following example</p> <pre>example% volcheck -v /dev/diskette /dev/diskette has media</pre> <p>asks Volume Management to examine the floppy drive for new media.</p> <p>The following example</p> <pre>example% volcheck -i 2 -t 600 /dev/diskette1 &</pre> <p>asks Volume Management if there is a floppy in the floppy drive every 2 seconds for 600 seconds (10 minutes).</p>				
FILES	<code>/dev/volctl</code> Volume Management control port				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWvolu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWvolu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWvolu				
SEE ALSO	<code>eject(1)</code> , <code>volcancel(1)</code> , <code>volmissing(1)</code> , <code>rmmount(1M)</code> , <code>vold(1M)</code> , <code>rmmount.conf(4)</code> , <code>vold.conf(4)</code> , <code>attributes(5)</code> , <code>volfs(7FS)</code>				

volcheck(1)

WARNINGS | Due to a hardware limitation in many floppy drives, the act of checking for media causes mechanical action in the floppy drive. Continuous polling of the floppy drive will cause the drive to wear out. It is recommended that polling the drive only be performed during periods of high use.

NAME	volmissing – notify user that volume requested is not in the CD-ROM or floppy drive				
SYNOPSIS	<code>/usr/lib/vold/volmissing [-c] [-p] [-s] [-m <i>alias</i>]</code>				
DESCRIPTION	<p>volmissing informs a user when a requested volume is not available. Depending on the option selected, users are notified through their console window, syslogd(1M), or a mail message.</p> <p>volmissing -p is the default action taken by vold(1M), the Volume Management daemon, when it needs to notify a user that the requested volume is not available. If you want to change this default event, modify the <code>/etc/vold.conf</code> file. See vold.conf(4).</p> <p>You can change the notification method for your system by editing the <code>vold.conf</code> configuration file and providing a new option for volmissing in the notify entry under the Events category.</p>				
OPTIONS	<p>-c Send a message to the user's console requesting the volume be inserted. To end the notification without inserting the requested volume, use volcancel(1).</p> <p>-p All volmissing events will be handled through a GUI, provided a window system is running on the console. If this option is specified, and no window system is running, all messages go to the system console.</p> <p>-s Send one message to the syslogd(1M).</p> <p>-m <i>alias</i> Send a mail message to the specified mail alias about the missing volume.</p>				
FILES	<p><code>/etc/vold.conf</code> Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes action to be taken when specific criteria is met.</p> <p><code>/usr/lib/vold/volmissing_popup</code> Pop-up used when the -p option is supplied and a window system is running.</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWvolu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWvolu

volrmmount(1)

NAME	volrmmount – call rmmount to mount or unmount media
SYNOPSIS	volrmmount [-i -e] [<i>name</i> <i>nickname</i>] volrmmount [-d]
DESCRIPTION	<p>The <code>volrmmount</code> utility calls <code>rmmount(1M)</code> to, in effect, simulate an insertion (-i) or an ejection (-e). Simulating an insertion often means that <code>rmmount</code> will mount the media. Conversely, simulating an ejection often means that <code>rmmount</code> will unmount the media. However, these actions can vary depending on the <code>rmmount</code> configuration and media type (see <code>rmmount.conf(4)</code>).</p> <p>For example, if you use the default <code>/etc/rmmount.conf</code> and insert a music CD, it will not be mounted. However, you can configure <code>rmmount</code> so that it calls <code>workman</code> whenever a music CD is inserted.</p> <p>This command allows you to override Volume Management's usual handling of media (see EXAMPLES below).</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-i Simulates an insertion of the specified media by calling <code>rmmount</code>.-e Simulates an ejection of the specified media by calling <code>rmmount</code>.-d Displays the name of the default device for <code>volrmmount</code> to handle. This device is used if no <i>name</i> or <i>nickname</i> is supplied.
OPERANDS	<p>The following operands are supported:</p> <p><i>name</i> The name that Volume Management recognizes as the device's name. See <code>volfs(7FS)</code>.</p> <p><i>nickname</i> A shortened version of the device's name. Following is the list of recognized nicknames:</p>

Nickname	Path
fd	/dev/rdiskette
fd0	/dev/rdiskette
fd1	/dev/rdiskette1
diskette	/dev/rdiskette
diskette0	/dev/rdiskette0
diskette1	/dev/rdiskette1
rdiskette	/dev/rdiskette
rdiskette0	/dev/rdiskette0

Nickname	Path
rdiskette1	/dev/rdiskette1
floppy	/dev/rdiskette
floppy0	/dev/rdiskette0
floppy1	/dev/rdiskette1
cdrom0	/vol/dev/rdisk/cXtYdZ/label
zip0	/vol/dev/rdisk/cXtYdZ/label
jaz0	/vol/dev/rdisk/cXtYdZ/label
rmdisk0	/vol/dev/rdisk/cXtYdZ/label

EXAMPLES **EXAMPLE 1** Using the volrmmount command

When Volume Management finds a floppy that contains a filesystem, it calls `rmmount` to mount it. If you wish to run `tar(1)` or `cpio(1)` on that floppy, it must first be unmounted. To unmount the floppy use:

```
example% volrmmount -e floppy0
```

After `volrmmount` unmounts the floppy, if you wish to re-mount it (rather than ejecting it and reinserting it) use:

```
example% volrmmount -i floppy0
```

Notice that if you are using a named floppy, you can use its name in place of `floppy0`.

FILES /dev/volctl Volume Management control port

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWvolu

SEE ALSO `cpio(1)`, `eject(1)`, `tar(1)`, `rmmount(1M)`, `vold(1M)`, `rmmount.conf(4)`, `attributes(5)`, `volfs(7FS)`

NOTES Volume Management (`vold`) must be running to use this command.

vsig(1F)

NAME vsig – synchronize a co-process with the controlling FMLI application

SYNOPSIS **vsig**

DESCRIPTION The `vsig` executable sends a `SIGUSR2` signal to the controlling FMLI process. This signal/alarm causes FMLI to execute the FMLI built-in command `checkworld` which causes all posted objects with a `reread` descriptor evaluating to `TRUE` to be reread. `vsig` takes no arguments.

EXAMPLES **EXAMPLE 1** A sample output of `vsig` command.

The following is a segment of a shell program:

```
echo "Sending this string to an FMLI process"
vsig
```

The `vsig` executable will flush the output buffer *before* it sends the `SIGUSR2` signal to make sure the string is actually in the pipe created by the `cocreate` function.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO `coproc(1F)`, `kill(1)`, `kill(2)`, `signal(3C)`, `attributes(5)`

NOTES Because `vsig` synchronize with FMLI, it should be used rather than `kill` to send a `SIGUSR2` signal to FMLI.

NAME	w – display information about currently logged-in users
SYNOPSIS	w [-hlsuw] [<i>user</i>]
DESCRIPTION	<p>The w command displays a summary of the current activity on the system, including what each user is doing. The heading line shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes.</p> <p>The fields displayed are: the user’s login name, the name of the tty the user is on, the time of day the user logged on (in <i>hours:minutes</i>), the idle time—that is, the number of minutes since the user last typed anything (in <i>hours:minutes</i>), the CPU time used by all processes and their children on that terminal (in <i>minutes:seconds</i>), the CPU time used by the currently active processes (in <i>minutes:seconds</i>), and the name and arguments of the current process.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -h Suppresses the heading. -l Produces a long form of output, which is the default. -s Produces a short form of output. In the short form, the tty is abbreviated, the login time and CPU times are left off, as are the arguments to commands. -u Produces the heading line which shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. -w Produces a long form of output, which is also the same as the default.
OPERANDS	<i>user</i> Name of a particular user for whom login information is displayed. If specified, output is restricted to that user.
EXAMPLES	<p>EXAMPLE 1 Sample Output From the w Command</p> <pre>example% w 10:54am up 27 day(s), 57 mins, 1 user, load average: 0.28, 0.26, 0.22 User tty login@ idle JCPU PCPU what ralph console 7:10am 1 10:05 4:31 w example% w 10:54am up 27 day(s), 57 mins, 1 user, load average: 0.28, 0.26, 0.22 User tty login@ idle JCPU PCPU what ralph console 7:10am 1 10:05 4:31 w</pre>
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of w: LC_CTYPE, LC_MESSAGES, and LC_TIME.
FILES	/var/adm/utmpx user and accounting information

w(1)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `ps(1)`, `who(1)`, `whodo(1M)`, `utmpx(4)`, `attributes(5)`, `environ(5)`

NOTES The notion of the “current process” is unclear. The current algorithm is ‘the highest numbered process on the terminal that is not ignoring interrupts, or, if there is none, the highest numbered process on the terminal’. This fails, for example, in critical sections of programs like the shell and editor, or when faulty programs running in the background fork and fail to ignore interrupts. In cases where no process can be found, `w` prints –.

The CPU time is only an estimate, in particular, if someone leaves a background process running after logging out, the person currently on that terminal is “charged” with the time.

Background processes are not shown, even though they account for much of the load on the system.

Sometimes processes, typically those in the background, are printed with null or garbaged arguments. In these cases, the name of the command is printed in parentheses.

`w` does not know about the conventions for detecting background jobs. It will sometimes find a background job instead of the right one.

NAME	wait – await process completion
SYNOPSIS	
/bin/sh	wait [<i>pid</i> ...]
/bin/jsh /bin/ksh	wait [<i>pid</i> ...]
/usr/xpg4/bin/sh	wait [% <i>jobid</i> ...]
/bin/csh	wait
DESCRIPTION	<p>The shell itself executes <code>wait</code>, without creating a new process. If you get the error message <code>cannot fork, too many processes</code>, try using the <code>wait</code> command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. There is a limit to the number of process IDs associated with your login, and to the number the system can keep track of.</p> <p>Not all the processes of a pipeline with three or more stages are children of the shell, and thus cannot be waited for.</p>
/bin/sh, /bin/jsh	<p>Wait for your background process whose process ID is <i>pid</i> and report its termination status. If <i>pid</i> is omitted, all your shell's currently active background processes are waited for and the return code will be 0. The <code>wait</code> utility accepts a job identifier, when Job Control is enabled (jsh), and the argument, <i>jobid</i>, is preceded by a percent sign (%).</p> <p>If <i>pid</i> is not an active process ID, the <code>wait</code> utility will return immediately and the return code will be 0.</p>
csh	Wait for your background processes.
ksh	<p>When an asynchronous list is started by the shell, the process ID of the last command in each element of the asynchronous list becomes known in the current shell execution environment.</p> <p>If the <code>wait</code> utility is invoked with no operands, it will wait until all process IDs known to the invoking shell have terminated and exit with an exit status of 0.</p> <p>If one or more <i>pid</i> or <i>jobid</i> operands are specified that represent known process IDs (or jobids), the <code>wait</code> utility will wait until all of them have terminated. If one or more <i>pid</i> or <i>jobid</i> operands are specified that represent unknown process IDs (or jobids), <code>wait</code> will treat them as if they were known process IDs (or jobids) that exited with exit status 127. The exit status returned by the <code>wait</code> utility will be the exit status of the process requested by the last <i>pid</i> or <i>jobid</i> operand.</p> <p>The known process IDs are applicable only for invocations of <code>wait</code> in the current shell execution environment.</p>
OPERANDS	The following operands are supported:

wait(1)

One of the following:

pid The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination.

jobid A job control job ID that identifies a background process group to be waited for. The job control job ID notation is applicable only for invocations of `wait` in the current shell execution environment, and only on systems supporting the job control option.

USAGE On most implementations, `wait` is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following,

```
(wait)
nohup wait ...
find . -exec wait ... \;
```

it will return immediately because there will be no known process IDs to wait for in those environments.

EXAMPLES **EXAMPLE 1** Using A Script To Identify The Termination Signal

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably figure out which signal is using `kill`, as shown by the following (`/bin/ksh` and `/usr/xpg4/bin/sh`):

```
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
echo $pid was terminated by a SIG$(kill -l ${ $?-128}) signal.
```

EXAMPLE 2 Returning The Exit Status Of A Process

If the following sequence of commands is run in less than 31 seconds (`/bin/ksh` and `/usr/xpg4/bin/sh`):

```
sleep 257 | sleep 31 &

jobs -l %%
```

then either of the following commands will return the exit status of the second `sleep` in the pipeline:

```
wait <pid of sleep 31>
wait %%
```

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `wait`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

wc(1)

NAME	wc – display a count of lines, words and characters in a file
SYNOPSIS	wc [-c -m -C] [-l _w] [<i>file</i> ...]
DESCRIPTION	<p>The wc utility reads one or more input files and, by default, writes the number of newline characters, words and bytes contained in each input file to the standard output.</p> <p>The utility also writes a total count for all named files, if more than one input file is specified.</p> <p>wc considers a <i>word</i> to be a non-zero-length string of characters delimited by white space (for example, <code>SPACE</code>, <code>TAB</code>). See <code>iswspace(3C)</code> or <code>isspace(3C)</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -c Counts bytes. -C Same as -m. -l Counts lines. -m Counts characters. -w Counts words delimited by white space characters or new line characters. Delimiting characters are Extended Unix Code (EUC) characters from any code set defined by <code>iswspace()</code>. <p>If no option is specified, the default is <code>-lwc</code> (counts lines, words, and bytes.)</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>file</i> A path name of an input file. If no <i>file</i> operands are specified, the standard input will be used.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of wc when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of wc : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 Successful completion. >0 An error occurred.

what(1)

NAME	what – extract SCCS version information from a file						
SYNOPSIS	what [-s] <i>filename</i> ...						
DESCRIPTION	The what utility searches each <i>filename</i> for occurrences of the pattern @ (#) that the SCCS get command (see <code>sccs-get(1)</code>) substitutes for the %Z% ID keyword, and prints what follows up to a ", >, NEWLINE, \, or NULL character.						
OPTIONS	The following option is supported: -s Stops after the first occurrence of the pattern.						
EXAMPLES	EXAMPLE 1 Extracting SCCS version information If a C program in file <code>program.c</code> contains <pre>char sccsid[] = " @(#)identification information ";</pre> and <code>program.c</code> is compiled to yield <code>program.o</code> and <code>a.out</code> , the command: <pre>example% what program.c program.o a.out</pre> produces: <pre>program.c: identification information program.o: identification information a.out: identification information</pre>						
EXIT STATUS	The following exit values are returned: 0 Any matches were found. 1 No matches found.						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of what: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWspot</td></tr><tr><td>Interface Stability</td><td>Standard</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWspot	Interface Stability	Standard

what(1)

DIAGNOSTICS Use the `SCCS help` command for explanations (see `sccs-help(1)`).

BUGS There is a remote possibility that a spurious occurrence of the '@(#)' pattern could be found by `what`.

whatis(1)

NAME | `whatis` – display a one-line summary about a keyword

SYNOPSIS | `whatis` *command*...

DESCRIPTION | `whatis` looks up a given *command* and displays the header line from the manual section. You can then run the `man(1)` command to get more information. If the line starts '*name (section) ...*' you can do '`man -s section name`' to get the documentation for it. Try '`whatis ed`' and then you should do '`man -s 1 ed`' to get the manual page for `ed(1)`.

| `whatis` is actually just the `-f` option to the `man(1)` command.

| `whatis` uses the `/usr/share/man/windex` database. This database is created by `catman(1M)`. If this database does not exist, `whatis` will fail.

FILES | `/usr/share/man/windex` | Table of contents and keyword database

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

NAME	whereis – locate the binary, source, and manual page files for a command
SYNOPSIS	<code>/usr/ucb/whereis [-bmsu] [-BMS directory... -f] filename...</code>
DESCRIPTION	<p>The <code>whereis</code> utility locates source/binary and manuals sections for specified files. The supplied names are first stripped of leading pathname components and any (single) trailing extension of the form <code>.ext</code>, for example, <code>.c</code>. Prefixes of <code>s.</code> resulting from use of source code control are also dealt with. <code>whereis</code> then attempts to locate the desired program in a list of standard places:</p> <pre> etc /sbin /usr/bin /usr/ccs/bin /usr/ccs/lib /usr/lang /usr/sbin /usr/lib /usr/sbin /usr/ucb /usr/ucblib /usr/ucbinclude /usr/games /usr/local /usr/local/bin /usr/new /usr/old /usr/hosts /usr/include /usr/etc </pre>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -b Searches only for binaries. -B Changes or otherwise limits the places where <code>whereis</code> searches for binaries. -f Terminates the last directory list and signals the start of file names, and <i>must</i> be used when any of the <code>-B</code>, <code>-M</code>, or <code>-S</code> options are used. -m Searches only for manual sections. -M Changes or otherwise limits the places where <code>whereis</code> searches for manual sections. -s Searches only for sources. -S Changes or otherwise limit the places where <code>whereis</code> searches for sources. -u Searches for unusual entries. A file is said to be unusual if it does not have one entry of each requested type. Thus <code>'whereis -m -u *'</code> asks for those files in the current directory which have no documentation.

whereis(1B)

EXAMPLES

EXAMPLE 1 Finding files

Find all files in /usr/bin which are not documented in /usr/share/man/man1 with source in /usr/src/cmd:

```
example% cd /usr/ucb
example% whereis -u -M /usr/share/man/man1 -S /usr/src/cmd -f *
```

FILES

/usr/src/*
/usr/{doc,man}/*
/etc, /usr/{lib,bin,ucb,old,new,local}

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO

chdir(2), attributes(5)

BUGS

Since whereis uses chdir(2) to run faster, pathnames given with the -M, -S, or -B must be full; that is, they must begin with a '/'.

- NAME** | which – locate a command; display its pathname or alias
- SYNOPSIS** | **which** [*filename...*]
- DESCRIPTION** | **which** takes a list of names and looks for the files which would be executed had these names been given as commands. Each argument is expanded if it is aliased, and searched for along the user’s path. Both aliases and path are taken from the user’s `.cshrc` file.
- FILES** | `~/ .cshrc` source of aliases and path values
`/usr/bin/which`
- ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

- SEE ALSO** | `csh(1)`, `attributes(5)`
- DIAGNOSTICS** | A diagnostic is given for names which are aliased to more than a single word, or if an executable file with the argument name was not found in the path.
- NOTES** | `which` is not a shell built-in command; it is the UNIX command, `/usr/bin/which`
- BUGS** | Only aliases and paths from `~/ .cshrc` are used; importing from the current environment is not attempted. Must be executed by `csh(1)`, since only `csh` knows about aliases.
- To compensate for `~/ .cshrc` files in which aliases depend upon the `prompt` variable being set, `which` sets this variable to NULL. If the `~/ .cshrc` produces output or prompts for input when `prompt` is set, `which` may produce some strange results.

who(1)

NAME	who – who is on the system																
SYNOPSIS	<pre>/usr/bin/who [-abdHlmpqrstTu] [file] /usr/bin/who -q [-n x] [file] /usr/bin/who am i /usr/bin/who am I /usr/xpg4/bin/who [-abdHlmpqrstTu] [file] /usr/xpg4/bin/who -q [-n x] [file] /usr/xpg4/bin/who -s [-bdHlmpqrtu] [file] /usr/xpg4/bin/who am i /usr/xpg4/bin/who am I</pre>																
DESCRIPTION	<p>The who utility can list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process-ID of the command interpreter (shell) for each current UNIX system user. It examines the <code>/var/adm/utmpx</code> file to obtain its information. If <i>file</i> is given, that file (which must be in utmpx(4) format) is examined. Usually, <i>file</i> will be <code>/var/adm/wtmpx</code>, which contains a history of all the logins since the file was last created.</p> <p>The general format for output is:</p> <pre>name [state] line time [idle] [pid] [comment] [exit]</pre> <p>where:</p> <table><tr><td><i>name</i></td><td>User's login name</td></tr><tr><td><i>state</i></td><td>Capability of writing to the terminal</td></tr><tr><td><i>line</i></td><td>Name of the line found in <code>/dev</code></td></tr><tr><td><i>time</i></td><td>Time since user's login</td></tr><tr><td><i>idle</i></td><td>Time elapsed since the user's last activity</td></tr><tr><td><i>pid</i></td><td>User's process id</td></tr><tr><td><i>comment</i></td><td>Comment line in <code>inittab(4)</code></td></tr><tr><td><i>exit</i></td><td>Exit status for dead processes</td></tr></table>	<i>name</i>	User's login name	<i>state</i>	Capability of writing to the terminal	<i>line</i>	Name of the line found in <code>/dev</code>	<i>time</i>	Time since user's login	<i>idle</i>	Time elapsed since the user's last activity	<i>pid</i>	User's process id	<i>comment</i>	Comment line in <code>inittab(4)</code>	<i>exit</i>	Exit status for dead processes
<i>name</i>	User's login name																
<i>state</i>	Capability of writing to the terminal																
<i>line</i>	Name of the line found in <code>/dev</code>																
<i>time</i>	Time since user's login																
<i>idle</i>	Time elapsed since the user's last activity																
<i>pid</i>	User's process id																
<i>comment</i>	Comment line in <code>inittab(4)</code>																
<i>exit</i>	Exit status for dead processes																
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Processes <code>/var/adm/utmpx</code> or the named <i>file</i> with <code>-b</code>, <code>-d</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, <code>-t</code>, <code>-T</code>, and <code>-u</code> options turned on.-b Indicates the time and date of the last reboot.-d Displays all processes that have expired and not been respawned by <code>init</code>. The <code>exit</code> field appears for dead processes and contains the termination																

		and exit values (as returned by <code>wait(3UCB)</code>), of the dead process. This can be useful in determining why a process terminated.
	-H	Outputs column headings above the regular output.
	-l	Lists only those lines on which the system is waiting for someone to login. The <i>name</i> field is <code>LOGIN</code> in such cases. Other fields are the same as for user entries except that the <i>state</i> field does not exist.
	-m	Outputs only information about the current terminal.
	-n <i>x</i>	Takes a numeric argument, <i>x</i> , which specifies the number of users to display per line. <i>x</i> must be at least 1. The <code>-n</code> option can only be used with <code>-q</code> .
	-p	Lists any other process that is currently active and has been previously spawned by <code>init</code> . The <i>name</i> field is the name of the program executed by <code>init</code> as found in <code>/sbin/inittab</code> . The <i>state</i> , <i>line</i> , and <i>idle</i> fields have no meaning. The <i>comment</i> field shows the <code>id</code> field of the line from <code>/sbin/inittab</code> that spawned this process. See <code>inittab(4)</code> .
	-q	(Quick who) Displays only the names and the number of users currently logged on. When this option is used, all other options are ignored.
	-r	Indicates the current <i>run-level</i> of the <code>init</code> process.
	-s	(Default) Lists only the <i>name</i> , <i>line</i> , and <i>time</i> fields.
<code>/usr/bin/who</code>	-T	Same as the <code>-s</code> option, except that the <i>state</i> , <i>idle</i> , <i>pid</i> , and <i>comment</i> , fields are also written. <i>state</i> is one of the following characters: <ul style="list-style-type: none"> + The terminal allows write access to other users. - The terminal denies write access to other users. ? The terminal write-access state cannot be determined.
<code>/usr/xpg4/bin/who</code>	-T	Same as the <code>-s</code> option, except that the <i>state</i> field is also written. <i>state</i> is one of the characters listed under the <code>/usr/bin/who</code> version of this option. If the <code>-u</code> option is used with <code>-T</code> , the <i>idle</i> time is added to the end of the previous format.
	-t	Indicates the last change to the system clock (using the <code>date</code> utility) by <code>root</code> . See <code>su(1M)</code> and <code>date(1)</code> .
	-u	Lists only those users who are currently logged in. The <i>name</i> is the user's login name. The <i>line</i> is the name of the line as found in the directory <code>/dev</code> . The <i>time</i> is the time that the user logged in. The <i>idle</i> column contains the number of hours and minutes since activity last occurred on that particular line. A dot (.) indicates that the terminal has seen activity in the last minute and is therefore "current." If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry is marked <code>old</code> . This field is useful when trying to determine whether a person is working at the terminal or not. The <i>pid</i> is the process-ID of the user's shell.

who(1)

The *comment* is the comment field associated with this line as found in `/sbin/inittab` (see `inittab(4)`). This can contain information about where the terminal is located, the telephone number of the dataset, type of terminal if hard-wired, and so forth.

OPERANDS The following operands are supported:

`am i`
`am I` In the "C" locale, limits the output to describing the invoking user, equivalent to the `-m` option. The `am` and `i` or `I` must be separate arguments.

file Specifies a path name of a file to substitute for the database of logged-on users that `who` uses by default.

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `who`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred.

FILES

<code>/sbin/inittab</code>	Script for <code>init</code>
<code>/var/adm/utmpx</code>	Current user and accounting information
<code>/var/adm/wtmpx</code>	Historic user and accounting information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NOTES *Superuser:* After a shutdown to the single-user state, `who` returns a prompt. Since `/var/adm/utmpx` is updated at login time and there is no login in single-user state, `who` cannot report accurately on this state. The command, `who am i`, however, returns the correct information.

NAME | whoami – display the effective current username

SYNOPSIS | `/usr/ucb/whoami`

DESCRIPTION | whoami displays the login name corresponding to the current effective user ID. If you have used `su` to temporarily adopt another user, `whoami` will report the login name associated with that user ID. `whoami` gets its information from the `geteuid` and `getpwuid` library routines (see `getuid` and `getpwnam(3C)`, respectively).

FILES | `/etc/passwd` username data base

whocalls(1)

NAME	whocalls – report on the calls to a specific procedure				
SYNOPSIS	<code>/usr/ccs/bin/whocalls [-l <i>wholib</i>] [-s] <i>funcname executable</i> [<i>arguments...</i>]</code>				
DESCRIPTION	<p>whocalls is a simple example of a utility based on the <i>Link-Auditing</i> functionality of <code>ld.so.1(1)</code> that permits the tracking of a given function call. See the <i>Linker and Libraries Guide</i> for a detailed description of the <i>Link-Auditing</i> mechanism. The <i>executable</i> is run as normal with any associated arguments. Each time the procedure <i>funcname</i> is called, both the arguments to that procedure and a stack trace are displayed on standard output.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-l <i>wholib</i></code> Specifies an alternate <code>who.so</code> <i>Link-Auditing</i> library to use.<code>-s</code> When available, examines and uses the <code>.symtab</code> symbol table for local symbols. This is a little more expensive than using the <code>.dynsym</code> symbol table, but can produce more detailed stack trace information.				
EXAMPLES	<p>EXAMPLE 1 Tracking function calls</p> <p>This example tracks the calls to <code>printf()</code> made by a simple <code>helloworld</code> program:</p> <pre>example% whocalls printf helloworld printf(0x106e4, 0xef625310, 0xef621ba8) helloworld:main+0x10 helloworld:_start+0x5c Hello World</pre>

NAME	whois – Internet user name directory service				
SYNOPSIS	whois [-h <i>host</i>] <i>identifier</i>				
DESCRIPTION	<p>whois searches for an Internet directory entry for an <i>identifier</i> which is either a name (such as “Smith”) or a handle (such as “SRI-NIC”). To force a name-only search, precede the name with a period; to force a handle-only search, precede the handle with an exclamation point.</p> <p>To search for a group or organization entry, precede the argument with * (an asterisk). The entire membership list of the group will be displayed with the record.</p> <p>You may of course use an exclamation point and asterisk, or a period and asterisk together.</p>				
EXAMPLES	<p>EXAMPLE 1 Using The whois Command</p> <p>The command:</p> <pre>example% whois Smith</pre> <p>looks for the name or handle SMITH.</p> <p>The command:</p> <pre>example% whois !SRI-NIC</pre> <p>looks for the handle SRI-NIC only.</p> <p>The command:</p> <pre>example% whois .Smith, John</pre> <p>looks for the name JOHN SMITH only.</p> <p>Adding . . . to the name or handle argument will match anything from that point; that is, ZU . . . will match ZUL, ZUM, and so on.</p>

write(1)

NAME	write – write to another user
SYNOPSIS	write <i>user</i> [<i>terminal</i>]
DESCRIPTION	<p>The <code>write</code> utility reads lines from the user's standard input and writes them to the terminal of another user. When first invoked, it writes the message:</p> <pre>Message from <i>sender-login-id</i> (<i>sending-terminal</i>) [<i>date</i>]...</pre> <p>to <i>user</i>. When it has successfully completed the connection, the sender's terminal will be alerted twice to indicate that what the sender is typing is being written to the recipient's terminal.</p> <p>If the recipient wants to reply, this can be accomplished by typing</p> <pre>write <i>sender-login-id</i> [<i>sending-terminal</i>]</pre> <p>upon receipt of the initial message. Whenever a line of input as delimited by a NL, EOF, or EOL special character is accumulated while in canonical input mode, the accumulated data will be written on the other user's terminal. Characters are processed as follows:</p> <ul style="list-style-type: none">■ Typing the alert character will write the alert character to the recipient's terminal.■ Typing the erase and kill characters will affect the sender's terminal in the manner described by the <code>termios(3C)</code> interface.■ Typing the interrupt or end-of-file characters will cause <code>write</code> to write an appropriate message (EOT\n in the "C" locale) to the recipient's terminal and exit.■ Typing characters from LC_CTYPE classifications <code>print</code> or <code>space</code> will cause those characters to be sent to the recipient's terminal.■ When and only when the <code>stty iexten</code> local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable.■ Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a '^' followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-Z'. <p>To write to a user who is logged in more than once, the <i>terminal</i> argument can be used to indicate which terminal to write to. Otherwise, the recipient's terminal is the first writable instance of the user found in <code>/usr/adm/utmpx</code>, and the following informational message will be written to the sender's standard output, indicating which terminal was chosen:</p> <pre><i>user</i> is logged on more than one place. You are connected to <i>terminal</i>. Other locations are:<i>terminal</i></pre>

Permission to be a recipient of a `write` message can be denied or granted by use of the `mesg` utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The `write` utility will fail when the user lacks the appropriate privileges to perform the requested action.

If the character `!` is found at the beginning of a line, `write` calls the shell to execute the rest of the line as a command.

`write` runs `setgid()` (see `setuid(2)`) to the group ID `tty`, in order to have write permissions on other user's terminals.

The following protocol is suggested for using `write`: when you first `write` to another user, wait for them to `write` back before starting to send. Each person should end a message with a distinctive signal (that is, `(o)` for "over") so that the other person knows when to reply. The signal `(oo)` (for "over and out") is suggested when conversation is to be terminated.

OPERANDS The following operands are supported:

user User (login) name of the person to whom the message will be written. This operand must be of the form returned by the `who(1)` utility.

terminal Terminal identification in the same format provided by the `who` utility.

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `write`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 The addressed user is not logged on or the addressed user denies permission.

FILES `/var/adm/utmpx` user and accounting information for `write`
`/usr/bin/sh` Bourne shell executable file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

write(1)

SEE ALSO mail(1), mesg(1), pr(1), sh(1), talk(1), who(1), setuid (2), termios(3C), attributes(5), environ(5), standards(5)

DIAGNOSTICS

user is not logged on

The person you are trying to write to is not logged on.

Permission denied

The person you are trying to write to denies that permission (with mesg).

Warning: cannot respond, set mesg -y

Your terminal is set to mesg n and the recipient cannot respond to you.

Can no longer write to user

The recipient has denied permission (mesg n) after you had started writing.

NAME	xargs – construct argument lists and invoke utility
SYNOPSIS	xargs [-t] [-p] [-e <i>eofstr</i>] [-E <i>eofstr</i>] [-I <i>replstr</i>] [-i [<i>replstr</i>]] [-L <i>number</i>] [-l [<i>number</i>]] [-n <i>number</i> [-x]] [-s <i>size</i>] [<i>utility</i> <i>argument...</i>]
DESCRIPTION	<p>The <i>xargs</i> utility constructs a command line consisting of the <i>utility</i> and <i>argument</i> operands specified followed by as many arguments read in sequence from standard input as will fit in length and number constraints specified by the options. The <i>xargs</i> utility then invokes the constructed command line and waits for its completion. This sequence is repeated until an end-of-file condition is detected on standard input or an invocation of a constructed command line returns an exit status of 255.</p> <p>Arguments in the standard input must be separated by unquoted blank characters, or unescaped blank characters or newline characters. A string of zero or more non-double-quote (") and non-newline characters can be quoted by enclosing them in double-quotes. A string of zero or more non-apostrophe (') and non-newline characters can be quoted by enclosing them in apostrophes. Any unquoted character can be escaped by preceding it with a backslash (\). The <i>utility</i> will be executed one or more times until the end-of-file is reached. The results are unspecified if the utility named by <i>utility</i> attempts to read from its standard input.</p> <p>The generated command line length will be the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The <i>xargs</i> utility will limit the command line length such that when the command line is invoked, the combined argument and environment lists will not exceed {ARG_MAX}-2048 bytes. Within this constraint, if neither the -n nor the -s option is specified, the default command line length will be at least {LINE_MAX}.</p>
OPTIONS	<p>The following options are supported:</p> <p>-e <i>eofstr</i> Uses <i>eofstr</i> as the logical end-of-file string. Underscore (_) is assumed for the logical EOF string if neither -e nor -E is used. When the <i>eofstr</i> option-argument is omitted, the logical EOF string capability is disabled and underscores are taken literally. The <i>xargs</i> utility reads standard input until either end-of-file or the logical EOF string is encountered.</p> <p>-E <i>eofstr</i> Specifies a logical end-of-file string to replace the default underscore. The <i>xargs</i> utility reads standard input until either end-of-file or the logical EOF string is encountered.</p> <p>-I <i>replstr</i> Insert mode. <i>utility</i> is executed for each line from standard input, taking the entire line as a single argument, inserting it in <i>argument s</i> for each occurrence of <i>replstr</i>. A maximum of five arguments in <i>arguments</i> can each contain one or more instances of <i>replstr</i>. Any blank characters at the beginning of each line are ignored. Constructed arguments cannot grow larger than 255 bytes. Option -x is forced on. The -I and -i options are mutually exclusive; the last one specified takes effect.</p>

xargs(1)

-i [<i>replstr</i>]	This option is equivalent to -I <i>replstr</i> . The string { } is assumed for <i>replstr</i> if the option-argument is omitted.
-L <i>number</i>	The <i>utility</i> is executed for each non-empty <i>number</i> lines of arguments from standard input. The last invocation of <i>utility</i> will be with fewer lines of arguments if fewer than <i>number</i> remain. A line is considered to end with the first newline character unless the last character of the line is a blank character; a trailing blank character signals continuation to the next non-empty line, inclusive. The -L, -l, and -n options are mutually exclusive; the last one specified takes effect.
-l [<i>number</i>]	(The letter ell.) This option is equivalent to -L <i>number</i> . If <i>number</i> is omitted, 1 is assumed. Option -x is forced on.
-n <i>number</i>	Invokes <i>utility</i> using as many standard input arguments as possible, up to <i>number</i> (a positive decimal integer) arguments maximum. Fewer arguments will be used if: <ul style="list-style-type: none">■ The command line length accumulated exceeds the size specified by the -s option (or {LINE_MAX} if there is no -s option), or■ The last iteration has fewer than <i>number</i>, but not zero, operands remaining.
-p	Prompt mode. The user is asked whether to execute <i>utility</i> at each invocation. Trace mode (-t) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response (specific to the user's locale) read from /dev/tty will execute the command; otherwise, that particular invocation of <i>utility</i> is skipped.
-s <i>size</i>	Invokes <i>utility</i> using as many standard input arguments as possible yielding a command line length less than <i>size</i> (a positive decimal integer) bytes. Fewer arguments will be used if: <ul style="list-style-type: none">■ The total number of arguments exceeds that specified by the -n option, or■ The total number of lines exceeds that specified by the -L option, or■ End of file is encountered on standard input before <i>size</i> bytes are accumulated. <p>Values of <i>size</i> up to at least {LINE_MAX} bytes are supported, provided that the constraints specified in DESCRIPTION are met. It is not considered an error if a value larger than that supported by the implementation or exceeding the constraints specified in DESCRIPTION is given. xargs will use the largest value it supports within the constraints.</p>

- t Enables trace mode. Each generated command line will be written to standard error just prior to invocation.
- x Terminates if a command line containing *number* arguments (see the *-n* option above) or *number* lines (see the *-L* option above) will not fit in the implied or specified size (see the *-s* option above).

OPERANDS The following operands are supported:

- utility* The name of the utility to be invoked, found by search path using the `PATH` environment variable. (see `environ(5)`.) If *utility* is omitted, the default is the `echo(1)` utility. If the *utility* operand names any of the special built-in utilities in `shell_builtins(1)`, the results are undefined.
- argument* An initial option or operand for the invocation of *utility*.

USAGE The 255 exit status allows a utility being used by `xargs` to tell `xargs` to terminate if it knows no further invocations using the current data stream will succeed. Thus, *utility* should explicitly `exit` with an appropriate value to avoid accidentally returning with 255.

Notice that input is parsed as lines. Blank characters separate arguments. If `xargs` is used to bundle output of commands like `find dir -print` or `ls` into commands to be executed, unexpected results are likely if any filenames contain any blank characters or newline characters. This can be fixed by using `find` to call a script that converts each file found into a quoted string that is then piped to `xargs`. Notice that the quoting rules used by `xargs` are not the same as in the shell. They were not made consistent here because existing applications depend on the current rules and the shell syntax is not fully compatible with it. An easy rule that can be used to transform any string into a quoted form that `xargs` will interpret correctly is to precede each character in the string with a backslash (`\`).

On implementations with a large value for `{ARG_MAX}`, `xargs` may produce command lines longer than `{LINE_MAX}`. For invocation of utilities, this is not a problem. If `xargs` is being used to create a text file, users should explicitly set the maximum command line length with the *-s* option.

The `xargs` utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.

EXAMPLES **EXAMPLE 1** Using the `xargs` command

The following will move all files from directory `$1` to directory `$2`, and echo each move command just before doing it:

xargs(1)

EXAMPLE 1 Using the xargs command (Continued)

```
example% ls $1 | xargs -I {} -t mv $1/{ } $2/{ }
```

The following command will combine the output of the parenthesised commands onto one line, which is then written to the end of file log:

```
example% (logname; date; printf "%s\n" "$0 $*") | xargs >>log
```

The following command will invoke diff with successive pairs of arguments originally typed as command line arguments (assuming there are no embedded blank characters in the elements of the original argument list):

```
example% printf "%s\n" "$*" | xargs -n 2 -x diff
```

The user is asked which files in the current directory are to be archived. The files are archived into arch ; a, one at a time, or b, many at a time:

```
example% ls | xargs -p -L 1 ar -r arch  
ls | xargs -p -L 1 | xargs ar -r arch
```

The following will execute with successive pairs of arguments originally typed as command line arguments:

```
example% echo $* | xargs -n 2 diff
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of xargs: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

PATH Determine the location of *utility*.

EXIT STATUS

The following exit values are returned:

- | | |
|-------|---|
| 0 | All invocations of <i>utility</i> returned exit status 0. |
| 1–125 | A command line meeting the specified requirements could not be assembled, one or more of the invocations of <i>utility</i> returned a non-zero exit status, or some other error occurred. |
| 126 | The utility specified by <i>utility</i> was found but could not be invoked. |
| 127 | The utility specified by <i>utility</i> could not be found. |

If a command line meeting the specified requirements cannot be assembled, the utility cannot be invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits with exit status 255, the xargs utility will write a diagnostic message and exit without processing any remaining input.

xgettext(1)

NAME	xgettext – extract gettext call strings from C programs
SYNOPSIS	xgettext [-ns] [-a [-x <i>exclude-file</i>]] [-c <i>comment-tag</i>] [-d <i>default-domain</i>] [-j] [-m <i>prefix</i>] [-M <i>suffix</i>] [-p <i>pathname</i>] - <i>filename...</i> xgettext -h
DESCRIPTION	<p>The <code>xgettext</code> utility is used to automate the creation of portable message files (<code>.po</code>). A <code>.po</code> file contains copies of “C” strings that are found in ANSI C source code in <i>filename</i> or the standard input if ‘-’ is specified on the command line. The <code>.po</code> file can be used as input to the <code>msgfmt(1)</code> utility, which produces a binary form of the message file that can be used by application during run-time.</p> <p><code>xgettext</code> writes <i>msgid</i> strings from <code>gettext(3C)</code> calls in <i>filename</i> to the default output file <code>messages.po</code>. The default output file name can be changed by <code>-d</code> option. <i>msgid</i> strings in <code>dgettext()</code> calls are written to the output file <code>domainname.po</code> where <code>domainname</code> is the first parameter to the <code>dgettext()</code> call.</p> <p>By default, <code>xgettext</code> creates a <code>.po</code> file in the current working directory, and each entry is in the same order that the strings are extracted from <i>filenames</i>. When the <code>-p</code> option is specified, the <code>.po</code> file is created in the <i>pathname</i> directory. An existing <code>.po</code> file is overwritten.</p> <p>Duplicate <i>msgid</i>s are written to the <code>.po</code> file as comment lines. When the <code>-s</code> option is specified, the <code>.po</code> is sorted by the <i>msgid</i> string, and all duplicated <i>msgid</i>s are removed. All <i>msgstr</i> directives in the <code>.po</code> file are empty unless the <code>-m</code> option is used.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-n</code> Add comment lines to the output file indicating file name and line number in the source file where each extracted string is encountered. These lines appear before each <i>msgid</i> in the following format:</p> <pre># # File: <i>filename</i>, line: <i>line-number</i></pre> <p><code>-s</code> Generate output sorted by <i>msgid</i>s with all duplicate <i>msgid</i>s removed.</p> <p><code>-a</code> Extract all strings, not just those found in <code>gettext(3C)</code>, and <code>dgettext()</code> calls. Only one <code>.po</code> file is created.</p> <p><code>-c <i>comment-tag</i></code> The comment block beginning with <i>comment-tag</i> as the first token of the comment block is added to the output <code>.po</code> file as # delimited comments. For multiple domains, <code>xgettext</code> directs comments and messages to the prevailing text domain.</p> <p><code>-d <i>default-domain</i></code> Rename default output file from <code>messages.po</code> to <i>default-domain.po</i>.</p>

- j Join messages with existing message files. If a .po file does not exist, it is created. If a .po file does exist, new messages are appended. Any duplicate `msgid`s are commented out in the resulting .po file. Domain directives in the existing .po file are ignored. Results not guaranteed if the existing message file has been edited.
- m *prefix* Fill in the `msgstr` with *prefix*. This is useful for debugging purposes. To make `msgstr` identical to `msgid`, use an empty string (" ") for *prefix*.
- M *suffix* Fill in the `msgstr` with *suffix*. This is useful for debugging purposes.
- p *pathname* Specify the directory where the output files will be placed. This option overrides the current working directory.
- x *exclude-file* Specify a .po file that contains a list of `msgid`s that are not to be extracted from the input files. The format of *exclude-file* is identical to the .po file. However, only the `msgid` directive line in *exclude-file* is used. All other lines are simply ignored. The -x option can only be used with the -a option.
- h Print a help message on the standard output.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc

SEE ALSO `msgfmt(1)`, `gettext(3C)`, `attributes(5)`

NOTES `xgettext` is not able to extract cast strings, for example ANSI C casts of literal strings to `(const char *)`. This is unnecessary anyway, since the prototypes in `<libintl.h>` already specify this type.

In messages and translation notes, lines greater than 2048 characters are truncated to 2048 characters and a warning message is printed to `stderr`.

xstr(1)

NAME	<code>xstr</code> – extract strings from C programs to implement shared strings
SYNOPSIS	<pre>xstr -c <i>filename</i> [-v] [-l <i>array</i>] xstr [-l <i>array</i>] xstr <i>filename</i> [-v] [-l <i>array</i>]</pre>
DESCRIPTION	<p><code>xstr</code> maintains a file called <code>strings</code> into which strings in component parts of a large program are hashed. These strings are replaced with references to this common area. This serves to implement shared constant strings, which are most useful if they are also read-only.</p> <p>The command:</p> <pre>example% xstr -c <i>filename</i></pre> <p>extracts the strings from the C source in <code>name</code>, replacing string references by expressions of the form <code>&xstr[<i>number</i>]</code> for some number. An appropriate declaration of <code>xstr</code> is prepended to the file. The resulting C text is placed in the file <code>x.c</code>, to then be compiled. The strings from this file are placed in the <code>strings</code> data base if they are not there already. Repeated strings and strings which are suffixes of existing strings do not cause changes to the data base.</p> <p>After all components of a large program have been compiled, a file declaring the common <code>xstr</code> space called <code>xs.c</code> can be created by a command of the form:</p> <pre>example% xstr</pre> <p>This <code>xs.c</code> file should then be compiled and loaded with the rest of the program. If possible, the array can be made read-only (shared) saving space and swap overhead.</p> <p><code>xstr</code> can also be used on a single file. A command:</p> <pre>example% xstr <i>filename</i></pre> <p>creates files <code>x.c</code> and <code>xs.c</code> as before, without using or affecting any <code>strings</code> file in the same directory.</p> <p>It may be useful to run <code>xstr</code> after the C preprocessor if any macro definitions yield strings or if there is conditional code which contains strings which may not, in fact, be needed. <code>xstr</code> reads from the standard input when the argument <code>'-'</code> is given. An appropriate command sequence for running <code>xstr</code> after the C preprocessor is:</p> <pre>example% cc -E name.c xstr -c - example% cc -c x.c example% mv x.o name.o</pre> <p><code>xstr</code> does not touch the file <code>strings</code> unless new items are added; thus <code>make(1S)</code> can avoid remaking <code>xs.o</code> unless truly necessary.</p>

OPTIONS

`-c filename` Take C source text from *filename*.

`-v` Verbose: display a progress report indicating where new or duplicate strings were found.

`-l array` Specify the named *array* in program references to abstracted strings. The default array name is `xstr`.

FILES

`strings` data base of strings

`x.c` massaged C source

`xs.c` C source for definition of array "`xstr*(rq`

`/tmp/xs*` temp file when `xstr filename` doesn't touch `strings`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `make(1S)`, `attributes(5)`

BUGS If a string is a suffix of another string in the data base, but the shorter string is seen first by `xstr` both strings will be placed in the data base, when just placing the longer one there would do.

NOTES Be aware that `xstr` indiscriminately replaces all strings with expressions of the form `&xstr[number]` regardless of the way the original C code might have used the string. For example, you will encounter a problem with code that uses `sizeof()` to determine the length of a literal string because `xstr` will replace the literal string with a pointer that most likely will have a different size than the string's. To circumvent this problem:

- use `strlen()` instead of `sizeof()`; note that `sizeof()` returns the size of the array (including the null byte at the end), whereas `strlen()` doesn't count the null byte. The equivalent of `sizeof("xxx")` really is `(strlen("xxx")+1)`.
- use `#define` for operands of `sizeof()` and use the define'd version. `xstr` ignores `#define` statements. Make sure you run `xstr` on *filename* before you run it on the preprocessor.

You will also encounter a problem when declaring an initialized character array of the form

```
char x[] = "xxx";
```

`xstr` will replace `xxx` with an expression of the form `&xstr[number]` which will not compile. To circumvent this problem, use `static char *x = "xxx"` instead of `static char x[] = "xxx"`.

yacc(1)

NAME	yacc – yet another compiler-compiler
SYNOPSIS	<code>/usr/ccs/bin/yacc [-dltVv] [-b <i>file_prefix</i>] [-Q [y n]] [-P <i>parser</i>] [-p <i>sym_prefix</i>] <i>file</i></code>
DESCRIPTION	<p>The yacc command converts a context-free grammar into a set of tables for a simple automaton that executes an LALR(1) parsing algorithm. The grammar may be ambiguous. Specified precedence rules are used to break ambiguities.</p> <p>The output file, <code>y.tab.c</code>, must be compiled by the C compiler to produce a function <code>yyparse()</code>. This program must be loaded with the lexical analyzer program, <code>yylex()</code>, as well as <code>main()</code> and <code>yyerror()</code>, an error handling routine. These routines must be supplied by the user. The <code>lex(1)</code> command is useful for creating lexical analyzers usable by yacc.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-b <i>file_prefix</i></code> Uses <i>file_prefix</i> instead of <code>y</code> as the prefix for all output files. The code file <code>y.tab.c</code>, the header file <code>y.tab.h</code> (created when <code>-d</code> is specified), and the description file <code>y.output</code> (created when <code>-v</code> is specified), will be changed to <code>file_prefix.tab.c</code>, <code>file_prefix.tab.h</code>, and <code>file_prefix.output</code>, respectively.</p> <p><code>-d</code> Generates the file <code>y.tab.h</code> with the <code>#define</code> statements that associate the yacc user-assigned “token codes” with the user-declared “token names”. This association allows source files other than <code>y.tab.c</code> to access the token codes.</p> <p><code>-l</code> Specifies that the code produced in <code>y.tab.c</code> will not contain any <code>#line</code> constructs. This option should only be used after the grammar and the associated actions are fully debugged.</p> <p><code>-p <i>sym_prefix</i></code> Uses <i>sym_prefix</i> instead of <code>yy</code> as the prefix for all external names produced by yacc. The names affected include the functions <code>yyparse()</code>, <code>yylex()</code> and <code>yyerror()</code>, and the variables <code>yyval</code>, <code>yychar</code> and <code>yydebug</code>. (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names may also be affected by the <code>-p</code> option. However, the <code>-p</code> option does not affect <code>#define</code> symbols generated by yacc.</p> <p><code>-P <i>parser</i></code> Allows you to specify the parser of your choice instead of <code>/usr/ccs/bin/yaccpar</code>. For example, you can specify:</p> <pre>example% yacc -P ~/myparser parser.y</pre> <p><code>-Q[y n]</code> The <code>-Qy</code> option puts the version stamping information in <code>y.tab.c</code>. This allows you to know what version of yacc built the file. The <code>-Qn</code> option (the default) writes no version information.</p> <p><code>-t</code> Compiles runtime debugging code by default. Runtime debugging code is always generated in <code>y.tab.c</code> under conditional</p>

compilation control. By default, this code is not included when `y.tab.c` is compiled. Whether or not the `-t` option is used, the runtime debugging code is under the control of `YYDEBUG`, a preprocessor symbol. If `YYDEBUG` has a non-zero value, then the debugging code is included. If its value is 0, then the code will not be included. The size and execution time of a program produced without the runtime debugging code will be smaller and slightly faster.

- `-v` Prepares the file `y.output`, which contains a description of the parsing tables and a report on conflicts generated by ambiguities in the grammar.
- `-V` Prints on the standard error output the version information for yacc.

OPERANDS The following operand is required:

file A path name of a file containing instructions for which a parser is to be created.

EXAMPLES **EXAMPLE 1** Accessing the yacc library

Access to the yacc library is obtained with library search operands to `cc`. To use the yacc library main:

```
example% cc y.tab.c -ly
```

Both the `lex` library and the `yacc` library contain `main`. To access the `yacc` main:

```
example% cc y.tab.c lex.yy.c -ly -ll
```

This ensures that the `yacc` library is searched first, so that its `main` is used.

The historical yacc libraries have contained two simple functions that are normally coded by the application programmer. These library functions are similar to the following code:

```
#include <locale.h>
int main(void)
{
    extern int yyparse();

    setlocale(LC_ALL, "");

    /* If the following parser is one created by lex, the
       application must be careful to ensure that LC_CTYPE
       and LC_COLLATE are set to the POSIX locale. */
    (void) yyparse();
    return (0);
}

#include <stdio.h>
```

yacc(1)

EXAMPLE 1 Accessing the yacc library (Continued)

```
int yyerror(const char *msg)
{
    (void) fprintf(stderr, "%s\n", msg);
    return (0);
}
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of yacc: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

yacc can handle characters from EUC primary and supplementary codesets as one-token symbols. EUC codes may only be single character quoted terminal symbols. yacc expects `yylex()` to return a wide character (`wchar_t`) value for these one-token symbols.

EXIT STATUS

The following exit values are returned:

0 Successful completion.
>0 An error occurred.

FILES

`y.output` state transitions of the generated parser
`y.tab.c` source code of the generated parser
`y.tab.h` header file for the generated parser
`yacc.acts` temporary file
`yacc.debug` temporary file
`yacc.tmp` temporary file
`yaccpar` parser prototype for C programs

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool
Interface Stability	Standard

SEE ALSO

`cc(1B)`, `lex(1)`, `attributes(5)`, `environ(5)`, `standards(5)`

DIAGNOSTICS

The number of reduce-reduce and shift-reduce conflicts is reported on the standard error output. A more detailed report is found in the `y.output` file. Similarly, if some rules are not reachable from the start symbol, this instance is also reported.

NOTES

Because file names are fixed, at most one yacc process can be active in a given directory at a given time.

Users are encouraged to avoid using '\$' as part of any identifier name.

yes(1)

NAME | yes – generate repetitive affirmative output

SYNOPSIS | **yes** [*expletive*...]

DESCRIPTION | The *yes* utility repeatedly outputs *y*, or if *expletive* is given, it is output repeatedly, followed by a newline. Multiple arguments are output separated by spaces and followed by a newline. To terminate, type an interrupt character.

| *yes* can be used to respond programatically to programs that require an interactive response.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO | `attributes(5)`

NAME ypcat – print values in a NIS database

SYNOPSIS **ypcat** [-kx] [-d *ypdomain*] *mname*

DESCRIPTION The *ypcat* command prints out values in the NIS name service map specified by *mname*, which may be either a map name or a map nickname. Since *ypcat* uses the NIS network services, no NIS server is specified.

Refer to *ypfiles*(4) for an overview of the NIS name service.

OPTIONS

- k Display the keys for those maps in which the values are null or the key is not part of the value. None of the maps derived from files that have an ASCII version in */etc* fall into this class.
- d *ypdomain* Specify a domain other than the default domain.
- x Display map nicknames.

ATTRIBUTES See *attributes*(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO *ypmatch*(1), *ypfiles*(4), *attributes*(5)

ypmatch(1)

NAME	ypmatch – print the value of one or more keys from a NIS map				
SYNOPSIS	ypmatch [-k] [-t] [-d <i>domain</i>] <i>key</i> [<i>key...</i>] <i>mname</i> ypmatch -x				
DESCRIPTION	<p>ypmatch prints the values associated with one or more keys from the NIS's name services map specified by <i>mname</i>, which may be either a map name or a map nickname.</p> <p>Multiple keys can be specified; all keys will be searched for in the same map. The keys must be the same case and length. No pattern matching is available. If a key is not matched, a diagnostic message is produced.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-k Before printing the value of a key, print the key itself, followed by a colon (:).-t Inhibit map nickname translation.-d <i>domain</i> Specify a domain other than the default domain.-x Display the map nickname table. This lists the nicknames the command knows of, and indicates the map name associated with each nickname.				
OPERANDS	<p>The following operand is supported:</p> <p><i>mname</i> The NIS's name services map</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none">0 Successful operation.1 An error occurred.				
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWnisu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWnisu				
SEE ALSO	ypcat(1) , ypfiles(4) , attributes(5)				
NOTES	<p>ypmatch will fail with an RPC error message on yp operation if enough file descriptors are not available. The number of file descriptors should be increased if this occurs.</p>				

NAME	yppasswd – change your network password in the NIS database				
SYNOPSIS	yppasswd [<i>username</i>]				
DESCRIPTION	<p>The <code>yppasswd</code> utility changes the network password associated with the user <i>username</i> in the Network Information Service (NIS) database. If the user has done a <code>keylogin(1)</code>, and a <code>publickey/secretkey</code> pair exists for the user in the NIS <code>publickey.byname</code> map, <code>yppasswd</code> also re-encrypts the <code>secretkey</code> with the new password. The NIS password may be different from the local one on your own machine.</p> <p><code>yppasswd</code> prompts for the old NIS password, and then for the new one. You must type in the old password correctly for the change to take effect. The new password must be typed twice, to forestall mistakes.</p> <p>New passwords must be at least four characters long, if they use a sufficiently rich alphabet, and at least six characters long if monospace. These rules are relaxed if you are insistent enough. Only the owner of the name or the super-user may change a password; superuser on the root master will not be prompted for the old password, and does not need to follow password construction requirements.</p> <p>The NIS password daemon, <code>rpc.yppasswdd</code> must be running on your NIS server in order for the new password to take effect.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWnisu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWnisu				
SEE ALSO	<code>keylogin(1)</code> , <code>login(1)</code> , <code>nis+(1)</code> , <code>nispasswd(1)</code> , <code>passwd(1)</code> , <code>getpwnam(3C)</code> , <code>getspnam(3C)</code> , <code>secure_rpc(3NSL)</code> , <code>nsswitch.conf(4)</code> , <code>attributes(5)</code>				
WARNINGS	Even after the user has successfully changed his or her password using this command, the subsequent <code>login(1)</code> using the new password will be successful only if the user's password and shadow information is obtained from NIS. See <code>getpwnam(3C)</code> , <code>getspnam(3C)</code> , and <code>nsswitch.conf(4)</code> .				
NOTES	The use of <code>yppasswd</code> is discouraged, as it is now only a wrapper around the <code>passwd(1)</code> command, which should be used instead. Using <code>passwd(1)</code> with the <code>-r nis</code> option (see <code>nis+(1)</code>) will achieve the same results, and will be consistent across all the different name services available.				
BUGS	The update protocol passes all the information to the server in one RPC call, without ever looking at it. Thus, if you type your old password incorrectly, you will not be notified until after you have entered your new password.				

ypwhich(1)

NAME ypwhich – return name of NIS server or map master

SYNOPSIS **ypwhich** [-d *domain*] [[-t] -m [*mname*] | [-Vn] *hostname*]
ypwhich -x

DESCRIPTION ypwhich returns the name of the NIS server that supplies the NIS name services to a NIS client, or which is the master for a map. If invoked without arguments, it gives the NIS server for the local machine. If *hostname* is specified, that machine is queried to find out which NIS master it is using.

Refer to ypfiles(4) for an overview of the NIS name services.

OPTIONS

- d *domain* Use *domain* instead of the default domain.
- t This option inhibits map nickname translation.
- m *mname* Find the master NIS server for a map. No *hostname* can be specified with -m. *mname* can be a mapname, or a nickname for a map. When *mname* is omitted, produce a list of available maps.
- x Display the map nickname translation table.
- Vn Version of ypbind, V3 is default.

environment variables and shell variables — `csh`, 244
event designators — `csh`, 227
expressions and operators — `csh`, 232
filename completion — `csh`, 225
filename substitution — `csh`, 232
history substitution — `csh`, 226
I/O redirection — `csh`, 229
initialization and termination — `csh`, 224
interactive operation — `csh`, 224
job control — `csh`, 235
lexical structure — `csh`, 226
modifiers — `csh`, 228
noninteractive operation — `csh`, 224
quick substitution — `csh`, 229
signal handling — `csh`, 234
status reporting — `csh`, 235
variable substitution — `csh`, 230
word designators — `csh`, 227

C shell commands
— `%`, 243
— `:`, 235
— `@`, 243
— `alias`, 236
— `bg`, 236
— `break`, 236
— `breaksw`, 236

C shell commands (Continued)

- case, 236
- cd, 236
- chdir, 236
- continue, 236
- default, 236
- dirs, 236
- echo, 236
- else, 238
- end, 237
- endif, 238
- eval, 236
- exec, 237
- exit, 237
- fg, 237
- foreach, 237
- glob, 237
- goto, 237
- hashstat, 237
- history, 237
- if, 238
- jobs, 238
- kill, 238
- limit, 238
- login, 239
- logout, 239
- nice, 239
- nohup, 239
- notify, 240
- onintr, 240
- popd, 240
- pushd, 240
- rehash, 240
- repeat, 240
- set, 240
- setenv, 240
- shift, 241
- source, 241
- stop, 241
- suspend, 242
- switch, 242
- time, 242
- umask, 242
- unalias, 242
- unhash, 242
- unlimit, 243
- unset, 243
- unsetenv, 243

C shell commands (Continued)

- wait, 243
- while, 243
- cal — display a calendar, 108
- calculator, desk, — dc, 271
- calendar — reminder service, 109
- calendar, display — cal, 108
- call-graph, display profile data — gprof, 512
- call rmmount to mount or unmount media —
volrmmount, 1680
- cancel — cancel print requests, 111
- cancel user's request for removable media that
is not currently in drive — volcancel, 1676
- cat — concatenate and display files, 113
- cc — C compiler, 116
- cd — shell built-in functions to change the
current working directory, 118
- CD read and write — cdrw, 121
- CDPATH variable — sh, 1396
- cdrw — CD read and write, 121
- change a user's Kerberos password —
kpasswd, 584
- change file access and modification times —
touch, 1612
- change file access and modification times
— settime, 1574
- touch, 1574
- character translation — tr, 1585, 1590
- chdir — shell built-in functions to change the
current working directory, 118
- check spelling — spell, 1439
- check for media in a drive — volcheck, 1677
- check path names — pathchk, 1106
- checkeq — check eqn constructs, 344
- checknr — check nroff/troff files, 127
- chgrp — change the group ownership of a
file, 128
- chmod — change the permissions mode of a
file, 132
- chown — change owner of file, 138, 140
- cksum — write file checksums and sizes, 162
- clear — clear terminal screen, 170
- cmp — compare two files, 171
- cocheck — (FMLI utility) communicate with a
process, 183
- cocreate — (FMLI utility) communicate with a
process, 183

code formatter, formats program in nice style
 using troff — vgrind, 1661

code set, conversion utility — iconv, 542

codestroy — (FMLI utility) communicate with a
 process, 183

col — filters reverse line-feeds from two-column
 nroff text, 173

comm — select or reject lines common to two
 files, 175

command — execute a simple command, 177

command, describe — whatis, 1692

command options
 parse — getopt, 496
 parse — getoptcv, 498

commands
 display the last commands executed, in
 reverse order — lastcomm, 638
 locate a command; display its pathname or
 alias — which, 1695
 locate by keyword — apropos, 55

communications
 connect to remote system — cu, 258
 connect to remote system — tip, 1558
 decode binary files — uuencode, 1639
 encode binary files — uuencode, 1639
 system to system command execution —
 uux, 1650
 talk to another user — talk, 1509
 UNIX-to-UNIX copy — uucp, 1635
 user interface to a remote system using the
 TELNET protocol — telnet, 1527
 UUCP list of names — uuname, 1635
 UUCP log — uulog, 1635
 write to another user — write, 1702

Compaq Smart-2 EISA/PCI and Smart-2SL PCI
 Array Controller ioctl utility —
 smart2cfg, 1422

compare two files — diff, 281

compilers
 C compiler — cc, 116
 C program verifier — lint, 708
 regular expression compile — regcmp, 1261
 RPC protocol compiler — rpcgen, 1288

compress — compress files, 180

concatenate, files and display them — cat, 113

configure LLC2 interface parameters —
 llc2_config, 714

configure runtime linking environment —
 crle, 209

connect to remote system, — cu, 258

construct argument lists and invoke utility —
 xargs, 1705

continue — shell built-in functions to escape
 from or advance within a controlling while,
 for, foreach, or until loop, 106

control, audio mixer control — mixerctl, 916

control line printer — lpc, 761

control tracing and manipulate probe points in
 a process or the kernel — prex, 1191

convert binary log file to Common Log File
 format — ncab2clf, 977

convert binary TNF file to ASCII —
 tnfdump, 1567

convert FORTRAN carriage-control output to
 printable form — asa, 66

convert Red Hat Package (RPM) to cpio archive
 — rpm2cpio, 1293

convert units — units, 1629

coproc — (FMLI utility) communicate with a
 process, 183

copy
 archives — cpio, 191
 files — cp, 187

core image, of running processes — gcore, 457

coreceive — (FMLI utility) communicate with a
 process, 183

cosend — (FMLI utility) communicate with a
 process, 183

count blocks in file — sum, 1492

count lines, words, characters in file —
 wc, 1688

cp — copy files, 187

cpio — copy archives, 191

cpp — C preprocessor, 199

cpustrack — monitor process and LWP behavior
 using CPU performance counters, 205

create, bibliography — addbib, 34

create new task or change task or project of
 running process — newtask, 991

crle — configure runtime linking
 environment, 209

crontab — user crontab file, 219

crypt — encrypt, 223

csh — shell command interpreter with a C-like
 syntax, 224

csplit — split files based on context, 250
ct — spawn login to a remote terminal, 253
ctags — create a tags file for use with ex and vi, 255
cu — connect to remote system, 258
curve, smooth, interpolate — spline, 1442
cut — cut out selected fields of each line of a file, 264

D

date — display date and/or set date, 267
date
 prompts for a date — ckdate, 141
 provides error message for date — errdate, 141
 provides help message for date — helpdate, 141
 validates a date — valdate, 141
deallocate — deallocate devices, 275
debug tools, debugger — adb, 33
decode binary file — uudecode, 1639
decode files, — crypt, 223
decrypt — crypt, 223
define locale environment — localedef, 734
dependencies, dynamic, of executable files or shared objects — ldd, 676
deroff — remove nroff, troff, tbl and eqn constructs, 277
describe command — whatis, 1692
describe instruction set architectures — isainfo, 553
desk calculator, — dc, 271
determine which variant instruction set is optimal to use — optisa, 1084
devices
 allocation — allocate, 39
 deallocation — deallocate, 275
 eject media device from drive — eject, 334
 list_devices — list_devices, 710
df — display status of disk space on file systems, 278
dhcpcinfo — display value of parameters received through DHCP, 279
dictionary, system, find words — look, 751
diff — compare two files, 281

diff
 3-way — diff3, 285
 big — bdiff, 100
diff3 — display line-by-line differences between three text files, 285
diff command, side-by-side — sdiff, 1361
diffmk — mark differences between versions of a troff input file, 287
digestp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 801
dircmp — compares contents of directories, 288
directories
 compare contents — dircmp, 288
 list contents — ls, 778
 list contents of — ls, 784
 make — mkdir, 918
 make link to — ln, 727
 print working directory name — pwd, 1245
 remove — rmdir, 1273
dirname — delivers all but last level of path name, 93
dirs — shell built-in functions to change the current working directory, 118
dis — object code disassembler, 289
disable — disable LP printers, 340
disassembler, object code — dis, 289
disk usage, summary — du, 300
display editor — vi, 1665
display
 a list of all valid user names — dispuid, 292
 architecture of current host — arch, 61
 call-graph profile data — gprof, 512
 contents of directory — ls, 778
 current news — news, 990
 — date, 267
 disk usage — du, 303
 dynamic dependencies of executable files or shared objects — ldd, 676
 effective user name — whoami, 1699
 file names — ls, 784
 first few lines of files — head, 529
 group membership of user — groups, 524, 525
 how long the system has been up — uptime, 1633
 identifier of current host — hostid, 540

display (Continued)

- last commands executed, in reverse order — lastcomm, 638
- list of all valid group names — dispgid, 291
- login and logout information about users and terminals — last, 636
- name of current host — hostname, 541
- name of the user running the process — logname, 749
- printer queue — lpq, 765
- process status — ps, 1239
- processor type of current host — mach, 792
- selected lines from file — sed, 1371
- size or sizes of a page of memory — pagesize, 1088
- status of disk space on file system — df, 278
- status of local hosts — ruptime, 1305
- status of network hosts — rup, 1303
- users on system — users, 1634
- working directory name — pwd, 1245
- display discretionary file information — getfacl, 490
- display information about currently logged-in users — w, 1683
- display information about the address space of a process — pmap, 1152
- display names and references bound in FNS context — fnlist, 430
- display package parameter values — pkgparam, 1142
- display profile data — prof, 1223
- display reference bound to FNS name — fnlookup, 432
- display the internal versioning information of dynamic objects — pvs, 1242
- display the native instruction sets executable on this platform — isalist, 555
- display value of parameters received through DHCP — dhcpinfo, 279
- document production
 - check spelling — spell, 1439
 - check nroff/troff files — checknr, 127
 - create an inverted index to a bibliographic database — indexbib, 545
 - create or extend bibliography — addbib, 34
 - eliminate .so's from nroff input — soelim, 1424

document production (Continued)

- expand and insert references from a bibliographic database — refer, 1259
- filters reverse line-feeds from two-column nroff text — col, 173
- find references in a bibliographic database — lookbib, 752
- format and print a bibliographic database — roffbib, 1284
- format documents for display or line-printer — nroff, 1073
- format tables for nroff or troff — tbl, 1523
- mark differences between versions of a troff input file — diffmk, 287
- remove nroff, troff, tbl and eqn constructs — deroff, 277
- simple text formatters — fmt, 419
- sort a bibliographic database — sortbib, 1435
- troff postprocessor for PostScript printers — dpost, 297
- typeset mathematics — eqn, 344
- typeset or format documents — troff, 1593
- DOS
 - convert text file from DOS format to ISO format — dos2unix, 293
 - convert text file from ISO format to DOS format — unix2dos, 1631
- dos2unix — convert text file from DOS format to ISO format, 293
- download — host resident PostScript font downloader, 295
- download — prepends host resident PostScript fonts to files, 295
- dpost — troff postprocessor for PostScript printers, 297
- draw graph — graph, 517
- du — summarize disk usage, 300
- du — display disk usage per directory or file, 303
- dump — dump selected parts of an object file, 305
- dump selected parts of an object file — dump, 305
- dump selected parts of an object file — elfdump, 338
- dumps — show codeset table for the current locale, 308

dumpkeys — dump keyboard translation tables, 730

E

echo — (FMLI utility) put string on virtual output, 314
echo — echo arguments, 309
echo — echo arguments to standard output, 313
ed — text editor, 315
edit — text editor, 327
editing text, sed — stream editor, 1371
egrep — search a file for a pattern using full regular expressions, 331
eject — eject media device from drive, 334
elfdump — dump selected parts of an object file, 338
enable — enable LP printers, 340
encode binary file — uuencode, 1639
encode files, — crypt, 223
encryption key, user, change — chkey, 130
env — set environment for command invocation, 342
environment
 display variables — printenv, 1203
 set terminal characteristics — tset, 1604
environment variables, global, FMLI, 1382
eqn — mathematical typesetting, 344
eqn, remove nroff, troff, tbl and eqn constructs — deroff, 277
equations, typeset mathematics — eqn, 344
error — analyze error messages, 349
eval — shell built-in functions to execute other commands, 363
evaluate condition(s) — test, 1537
ex — text editor, 353
examine application-level products for unstable use of Solaris interfaces — appcert, 43
exec — shell built-in functions to execute other commands, 363
execute a command in a profile — pfcsh, 1127
execute a command in a profile — pfexec, 1127
execute a command in a profile — pfksh, 1127
execute a command in a profile — pfsh, 1127
execute commands at a later time — at, 68, 250

execute commands at a later time — batch batch, 68, 250
execute a simple command — command, 177
execute command in extended attribute name space — runat, 1300
exit — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 365
expand — expand TAB characters to SPACE characters, 367
export — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1377
exportfs — translates exportfs options to share/unshare commands, 369
expr — evaluate arguments as an expression, 370
expr — evaluate expressions, 373
expression evaluation — expr, 373
exstr — extract strings from source files, 376
extract kernel probes output into a trace file — tnfxtract, 1572
extract strings from C code — xstr, 1712

F

face — executable for the Framed Access Command Environment Interface, 380
factor — obtain the prime factors of a number, 381
false — provide truth values, 1596
fastboot — reboot system without checking disks, 382
fasthalt — halt system without checking disks, 382
fc — shell built-in functions to re-use previous command-lines from the current shell, 531
fdformat — format floppy diskette or PCMCIA memory card, 383
fg — shell built-in functions to control process execution, 556
fgrep — search file for fixed-character string, 387
file — determine file type, 389
file
 change ownership — chown, 140

file (Continued)

- determine type of — file, 391
- display names — ls, 784
- files perusal filter for CRTs — pg, 1128
- make link to — ln, 727
- print — lpr, 767
- strip affixes — basename, 95
- sum — sum and count blocks in file, 1492
- update last modified date of — touch, 1578

file — get file type, 391

file system

- display status of disk space — df, 278
- make hard or symbolic links to files — ln, 724
- where am I — pwd, 1245

file transfer program, — ftp, 444

filep — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 801

files

- change owner of file — chown, 138
- change the permissions mode of a file — chmod, 132
- compare two files — cmp, 171
- compress — compress, 180
- compress files — pack, 1085
- compress files — pcat, 1085
- concatenate and display — cat, 113
- copy — cp, 187
- copy archives — cpio, 191
- crypt — encrypt/decrypt, 223
- cut out selected fields of each line of a file — cut, 264
- display uncompressed files but leaves compressed files intact — zcat, 180
- display a count of lines, words and characters in a file — wc, 1688
- display first few lines — head, 529
- display last part — tail, 1506
- display line-by-line differences between pairs of large text files — bdiff, 100
- display line-by-line differences between three text files — diff3, 285
- expand compressed files — unpack, 1085
- extract SCCS version information from a file — what, 1690
- find, 400
- mark differences between versions of a troff input file — diffmk, 287

files (Continued)

- merge same lines of several files or subsequent lines of one file — paste, 1098
- move — mv, 951
- print checksum and block count for a file — sum, 1491
- print differences between two files
 - side-by-side — sdiff, 1361
- remove — rm, 1273
- search a file for a pattern — grep, 519
- search file for fixed-character string — fgrep, 387
- search for a pattern using full regular expressions — egrep, 331
- sort or merge — sort, 1428
- split a file into pieces — split, 1443
- strip affixes from path names —
 - basename, 93
- transfer to and from a remote machine —
 - tftp, 1549
 - uncompress — uncompress, 180

filesync — synchronize files and directories, 393

- Multiple Nomadic Machines, 395
- Rules File, 394

filofxp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 801

find — find files, 400

find or signal processes by name and other attributes

- pgrep, 1133
- pkill, 1133

fmlcut — (FMLI utility) cut out columns from a table or fields from each line of a file, 410

fmlexpr — (FMLI utility) evaluate arguments as an expression, 412

fmlgrep — (FMLI utility) search afile for a pattern, 414

FMLI

- cocheck — communicate with a process, 183
- cocreate — communicate with a process, 183
- codestroy — communicate with a process, 183
- coproc — communicate with a process, 183
- coreceive — communicate with a process, 183
- cosend — communicate with a process, 183

FMLI (Continued)

- echo — put string on virtual output, 314
- fmlcut — cut out columns from a table or fields from each line of a file, 410
- fmlexpr — evaluate arguments as an expression, 412
- fmlgrep — search afile for a pattern, 414
- fmli — invoke fmli, 416
- getfrm — returns the current frameID number, 494
- getitems — returns a list of currently marked menu items, 495
- indicator — displays application specific alarms or working indicator, or both, on FMLI banner line, 544
- message — puts arguments on FMLI message line, 914
- pathconv — converts an alias to its pathname, 1109
- readfile, longline — reads file, gets longest line, 1257
- regex — match patterns against a string, 1263
- reinit — changes the descriptors in the initialization file, 1265
- reset — (FLMI utility) changes the entry in a field of a form to its default value, 1269
- run — runs a program, 1298
- set, unset — set and unset local or global environment variables, 1382
- setcolor — redefine or create a color, 1384
- shell — run a command using shell, 1411
- test — evaluates the expression expression, 1547
- vsig — synchronize a co-process with the controlling FMLI application, 1682
- fmt — simple text formatters, 419
- fnattr — update and examine attributes associated with FNS named object, 425
- fnlist — display names and references bound in FNS context, 430
- fnlookup — display reference bound to FNS name, 432
- fnrename — rename the binding of an FNS name, 433
- FNS
 - display names and references — fnlist, 430

FNS (Continued)

- display reference bound to FNS name —
 - fnlookup, 432
 - search for FNS objects — fnsearch, 434
 - update attributes — fnattr, 425
- fnsearch — search for FNS objects with specified attributes, 434
 - Displaying Selected Attributes, 436
 - Extended Operations, 438
 - Filter Arguments, 436
 - Grammar of Filter Expressions, 438
 - Logical Operators, 435
 - Relational Operators, 435
 - Simple Filter Expressions, 435
 - Wildcarded Strings, 437
- fnunbind — unbind the reference from an FNS name, 440
- fold — fold long lines, 441
- fonts, prepends host resident PostScript fonts to files — download, 295
- force a defunct process to be reaped by its parent — preap, 1189
- format floppy diskette or PCMCIA memory card — fdformat, 383
- formatters, text, — fmt, 419
- Forms and Menu Language Interpreter
 - See FMLI
- FORTTRAN, create a tags file for use with ex and vi — ctags, 255
- Framed Access Command Environment
 - See face
- frameID number (FMLI utility) — getfrm, 494
- franklinp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 801
- from — sender of mail messages, 443
- frontends to the mp Text to PDL (Printer Description Language) pretty print filter —
 - digestp, 801
- frontends to the mp Text to PDL (Printer Description Language) pretty print filter —
 - filep, 801
- frontends to the mp Text to PDL (Printer Description Language) pretty print filter —
 - filofaxp, 801
- frontends to the mp Text to PDL (Printer Description Language) pretty print filter —
 - franklinp, 801

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — mailp, 801

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — newsp, 801

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — timemanp, 801

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — timesysp, 801

ftp — file transfer program, 444

ftpcount — show current number of users in each FTP Server class, 455

ftpwho — show current process information for each FTP Server user, 456

function calls, trace application function calls to Solaris shared libraries — apptrace, 50

G

gcore — get core images of running processes, 457

gencat — generate a formatted message catalog, 458

generate iconv code conversion tables — geniconvtbl, 461

generate LLC2 configuration files — llc2_autoconfig, 713

generate message source file from source files — genmsg, 479

generate programs for lexical tasks — lex, 690

generate repetitive affirmative output — yes, 1718

geniconvtbl — generate iconv code conversion tables, 461

genmsg — generate message source file from source files, 479

 Auto Message Numbering, 479

 Comment Extraction, 479

 Invocation, 479

 Testing, 479

get configuration values — getconf, 485

get locale-specific information — locale, 731

get or set the resource controls of running processes, tasks, and projects — prctl, 1186

get or set the resource limits of running processes, — plimit, 1148

getconf — get configuration values, 485

getfac — display discretionary file information, 490

getfrm — (FMLI utility) returns the current frameID number, 494

getitems — (FMLI utility) returns a list of currently marked menu items, 495

getopt — parse command options, 496

getoptcv — parse command options, 498

getopts — shell built-in function to parse command-line options, 501

gettext — retrieve text string from message database, 507

gettxt — retrieve text string from message database, 509

glob — shell built-in function to expand a word list, 511

goto — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 365

gprof — call-graph profile, 512

graph — draw graph, 517

graphics filters for plotters — plot, 1150

graphics filters for plotters — tplot, 1579

graphics, interpolate smooth curve — spline, 1442

grep

 search a file for a pattern — grep, 519

 search a file for a pattern using full regular expressions — egrep, 331

 search file for fixed-character string — fgrep, 387

group IDs

 change real and effective — newgrp, 988

 change the group ownership of a file — chgrp, 128

 display a list of all valid group names — dispgid, 291

 prompts for group ID — ckgid, 144

 provides error message for group ID — errgid, 144

 provides help message for group ID — helpgid, 144

 validates group ID — valgid, 144

groups — display group membership, 525

groups — print group membership of user, 524

grpck — check group database entries, 526

H

halt system without checking disks —
fasthalt, 382
hash — shell built-in functions to evaluate the
internal hash table of the contents of
directories, 527
hashstat — shell built-in functions to evaluate
the internal hash table of the contents of
directories, 527
head — display first few lines of files, 529
history — shell built-in functions to re-use
previous command-lines from the current
shell, 531
HOME variable — sh, 1396
host machines, local
show status — ruptime, 1305
who is logged in — rwho, 1309
host machines, remote
display status of network hosts (RPC
version) — rup, 1303
who is logged in — rusers, 1308
host resident PostScript font downloader —
download, 295
hostid — display host ID, 540
hostname — display host name, 541

I

i386 — get processor type truth value, 793
iAPX286 — get processor type truth value, 793
IFS variable — sh, 1397
indicator — (FMLI utility) displays application
specific alarms or working indicator, or both,
on FMLI banner line, 544
indxbib — create an inverted index to a
bibliographic database, 545
install — install files, 546
instruction set, determining which variant is
optimal to use — optisa, 1084
integer
prompts for an integer — ckint, 146
provides error message for integer —
errint, 146

integer (Continued)

provides help message for integer —
helpint, 146
validates an integer — valint, 146
integer, range
prompts for an integer within a specified
range — ckrange, 156
provides error message for integer within a
specified range — errrange, 156
provides help message for integer within a
specified range — helprange, 156
validate an integer within a specified range
— valrange, 156
interactive message processing system —
mail, 799
interactive message processing system —
Mail, 799
Internet
transfer files to and from a remote machine
— tftp, 1549
transfer of files to and from remote network
sites — ftp, 444
user name directory service — whois, 1701
interprocess communication
remove a message queue, semaphore set, or
shared memory ID — ipcrm, 548
report status — ipcs, 549
invoke a command with an altered scheduling
priority — nice, 994
ipcrm — remove a message queue, semaphore
set, or shared memory ID, 548
ipcs — report inter-process communication
facilities status, 549
isainfo — describe instruction set
architectures, 553
isalist — display the native instruction sets
executable on this platform, 555

J

jobs — shell built-in functions to control process
execution, 556
join — relational database operator, 563
jsh — the job control shell command
interpreter, 1393

K

kbd — manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect, 566

Kerberos keytab maintenance utility — ktutil, 634

Kerberos login utility, — kinit, 577

Kerberos tickets

- destroy — kdestroy, 569
- list currently held — klist, 582

keyboard

- load and dump keyboard translation tables — loadkeys, dumpkeys, 730
- manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect — kbd, 566

keylogin — decrypt and store secret key with keyserve, 570

keylogout — delete stored secret key with keyserve, 572

keywords, prompts for and validates a keyword — ckkeywd, 151

kill — terminate a process by default, 573

Korn shell commands, login command, 622

KornShell

- aliasing — ksh, 587
- arithmetic evaluation — ksh, 603
- blank interpretation — ksh, 602
- command execution — ksh, 610
- command re-entry — ksh, 611
- command substitution — ksh, 590
- commands — ksh, 585
- comments — ksh, 587
- conditional expressions — ksh, 603
- definitions — ksh, 585
- emacs editing mode — ksh, 612
- environment — ksh, 607
- file name generation — ksh, 602
- functions — ksh, 607
- I/O — ksh, 605
- in-line editing options — ksh, 611
- invocation — ksh, 630
- jobs — ksh, 609
- jobs — shell_builtins, 558
- parameter substitution — ksh, 593
- process substitution — ksh, 593
- prompting — ksh, 603

KornShell (Continued)

- quoting — ksh, 602
- restricted command and programming language — rksh, 585
- signals — ksh, 610
- special commands — ksh, 618
- tilde substitution — ksh, 589
- vi editing mode — ksh, 615

kpasswd — change a user's Kerberos password, 584

ksh — KornShell, a standard command and programming language, 585

ktutil — Kerberos keytab maintenance utility, 634

L

languages

- C compiler — cc, 116
- C preprocessor — cpp, 199
- C program verifier — lint, 708
- create C error messages — mkstr, 922
- extract strings from C code — xstr, 1712

last — display login and logout information about users and terminals, 636

lastcomm — display the last commands executed, in reverse order, 638

ld — link-editor for object files, 640

ld — link editor, 652

ld.so.1 — runtime linker for dynamic objects, 681

ldap — LDAP as a naming repository, 653

LDAP as a naming repository — ldap, 653

ldap delete entry tool — ldapdelete, 657

ldap entry addition and modification tools

- ldapadd, 664
- ldapmodify, 664

ldap modify entry RDN tool — ldapmodrdn, 668

ldap search tool — ldapsearch, 671

ldapadd — ldap entry addition and modification tools, 664

ldapdelete — ldap delete entry tool, 657

ldapmodify — ldap entry addition and modification tools, 664

ldapmodrdn — ldap modify entry RDN tool, 668

ldapmodrdn — ldap modify entry RDN tool
 (Continued)
 Input Format, 669
 ldapsearch — ldap search tool, 671
 Output Format, 671
 ldd — list dynamic dependencies of executable
 files or shared objects, 676
 let — shell built-in function to evaluate one or
 more arithmetic expressions, 689
 lex — generate programs for lexical tasks, 690
 Actions in lex, 697
 lex, create a tags file for use with ex and vi —
 ctags, 255
 lex — generate programs for lexical tasks
 Definitions in lex, 692
 Output Files, 691
 Regular Expressions in lex, 694
 Rules in lex, 694
 Stderr, 691
 Stdout, 690
 User Subroutines in lex, 694
 library archive, find ordering relation for an
 object or library archive — lorder, 753
 limit — set or get limitations on the system
 resources available to the current shell and
 its descendents, 702
 csh, 702
 ksh, 702
 sh, 702
 sh/ksh, 704
 /usr/bin/ulimit, 702
 line — read one line from standard input and
 write to standard output, 707
 line numbering filter — nl, 1060
 line printer control — lpc, 761
 link, make hard or symbolic links to files —
 ln, 724
 link editor — ld, 652
 link-editor — ld, 640
 lint — C program verifier, 708
 list
 contents of directory — ls, 778
 file names — ls, 784
 list, sorted, find lines — look, 751
 list_devices — list_devices, 710
 list of service grades, print — uuglist, 1642
 listusers — list user login information, 712
 llc2_autoconfig — generate LLC2 configuration
 files, 713
 llc2_config — configure LLC2 interface
 parameters, 714
 LLC2 Station, SAP, and Connection Statistics —
 llc2_stats, 716
 llc2_stats — LLC2 Station, SAP, and Connection
 Statistics, 716
 ln — make hard or symbolic links to files, 724
 loadkeys — load keyboard translation
 tables, 730
 locale — get locale-specific information, 731
 localedef — define locale environment, 734
 log, system, add entries — logger, 738
 logger — add entries to the system log, 738
 logger — make system log entry, 740
 login — sign on to the system, 742
 login command, 622, 1403
 login
 change login password and password
 attributes — passwd, 1091
 display effective user name — whoami, 1699
 display login and logout information about
 users and terminals — last, 636
 get the name of the user running the process
 — logname, 749
 list user login information — listusers, 712
 remote — rlogin, 1270
 spawn login to a remote terminal — ct, 253
 who is logged in, and what are they doing —
 w, 1683
 login environment
 display variables — printenv, 1203
 set terminal characteristics — tset, 1604
 login password, change in NIS —
 yppasswd, 1721
 logname — get the name of the user running
 the process, 749
 logout — shell built-in function to exit from a
 login session, 750
 logout, display login and logout information
 about users and terminals — last, 636
 look — find words in the system dictionary or
 lines in a sorted list, 751
 lookbib — find references in a bibliographic
 database, 752
 lorder — find ordering relation for an object or
 library archive, 753

lp — send requests to a print service, 754
 LP print services
 cancel requests — cancel, 111
 control line printer — lpc, 761
 display printer queue — lpq, 765
 generate printer test pattern — lptest, 777
 print files — lp, 754
 print files (BSD) — lpr, 767
 remove print jobs — lprm, 771
 lpc — line printer control, 761
 lpq — display printer queue, 765
 lpr — print files, 767
 lprm — remove print jobs, 771
 lpstat — print information about the status of
 the print service, 773
 lptest — generate printer test pattern, 777
 ls — list contents of directory, 778
 ls — list files, 784

M

m4 — macro processor, 787
 mach — display processor type of current
 host, 792
 machid — get processor type truth value, 793
 machine IDs, get processor type truth value —
 machid, 793
 macro processor — m4, 787
 madv library — madv.so.1, 795
 madv.so.1 — madv library, 795
 magnetic tape
 backspace files — mt, 948
 backspace records — mt, 948
 copy — tcopy, 1525
 erase — mt, 948
 forward space files — mt, 948
 forward space records — mt, 948
 get unit status — mt, 948
 manipulate — mt, 948
 place unit off-line — mt, 948
 retension — mt, 948
 rewind — mt, 948
 skip backward files — mt, 948
 skip backward records — mt, 948
 skip forward files — mt, 948
 skip forward records — mt, 948
 write EOF mark on — mt, 948

mail — interactive message processing
 system, 799
 Mail — interactive message processing
 system, 799
 MAIL variable — sh, 1396
 mail, automatic replies — vacation, 1654
 mail aliases, aliases— system mail, 1185
 mail services
 mail notifier — biff, 105
 sender of mail messages — from, 443
 mail utilities, statistics — mailstats, 805
 mailbox, storage for incoming mail —
 mailx, 807
 MAILCHECK variable — sh, 1396
 mailcompat — provide SunOS compatibility for
 Solaris mailbox format, 800
 mailp — frontends to the mp Text to PDL
 (Printer Description Language) pretty print
 filter, 801
 mailstats — mail delivery statistics, 805
 mailx — interactive message processing
 system, 807, 827
 mailx commands
 — !, 811
 — #, 811
 — =, 811
 — ?, 811
 — |, 815
 — z, 818
 — alias, 811
 — alternates, 811
 — cd, 811
 — chdir, 811
 — Copy, 811
 — copy, 811
 — delete, 811
 — discard, 812
 — dp, 812
 — dt, 812
 — echo, 812
 — edit, 812
 — else, 813
 — endif, 813
 — exit, 812
 — field, 812
 — file, 812
 — folder, 812
 — Followup, 813

mailx commands (Continued)

- followup, 813
- from, 813
- group, 811
- headers, 813
- help, 813
- hold, 813, 815
- if, 813
- ignore, 812
- inc, 813
- list, 814
- load, 814
- mail, 814
- mbox, 814
- More, 814
- New, 814
- new, 814
- next, 815
- Page, 814
- pipe, 815
- preserve, 813, 815
- Print, 815, 817
- print, 815, 817
- Put, 815
- put, 815
- quit, 815
- Reply, 816
- reply, 815
- replyall, 816
- replysender, 815
- Respond, 816
- respond, 815
- retain, 816
- Save, 816
- save, 816
- set, 816
- shell, 817
- size, 817
- source, 817
- top, 817
- touch, 817
- Type, 815, 817
- type, 815, 817
- unalias, 817
- undelete, 817
- undiscard, 817
- ungroup, 817
- unignore, 817

mailx commands (Continued)

- Unread, 814, 817
 - unread, 814, 817
 - unretain, 817
 - unset, 817
 - version, 818
 - visual, 818
 - write, 818
 - xit, 818
- maintain groups of programs —
sysV-make, 1495
- make — maintain, update, and regenerate related programs and files
- Appending to a Macro, 837
 - Bourne Shell Constructs, 857
 - Clearing Special Targets, 836
 - Command Dependencies, 836
 - Command Execution, 857
 - Command Substitutions, 857
 - Conditional Macro Definitions, 839
 - Dynamic Macros, 839
 - Global, 832
 - Hidden Dependencies, 836
 - Implicit Rules, 843
 - implicit rules, list of make/make.rules, 856
 - Library Maintenance, 856
 - Macros, 833, 836
 - Makefile Target Entries, 831
 - Pattern Matching Rules, 843
 - Pattern Replacement Macro References, 837
 - Predefined Macros, 840
 - Reading Makefiles and the Environment, 831
 - Rules, 834
 - Signals, 858
 - Special Characters, 832
 - Special-Function Targets, 834
 - Special-Purpose Macros, 837
 - Suffix Replacement Macro References, 837
 - Suffix Rules, 843
- make, System V version of make —
sysV-make, 1495
- make — maintain, update, and regenerate related programs and files
- Targets and Dependencies, 832
 - The Suffixes List, 856
- man — online display of reference pages, 863

manual pages
 accessing — man, 863
 describe command — whatis, 1692
 locate — whereis, 1693
 matrix display program for PostScript printers
 — postmd, 1166
 mbox, storage file for read mail — mailx, 807
 mconnect — open connection to remote mail
 server, 869
 mcs — manipulate the comment section of an
 object file, 870
 mdb — modular debugger, 872
 menu item
 builds a menu and prompts user to choose
 one item from menu — ckitem, 148
 provides error message for menu item —
 erritem, 148
 provides help message for menu item —
 helpitem, 148
 menu items, FMLL, returns a list of —
 getitems, 495
 mesg — permit or deny messages via
 write, 913
 message — puts arguments on FMLI message
 line, 914
 messages
 create message object file — msgfmt, 942
 display contents of, or search for a text string
 in, message data bases — srchtxt, 1445
 display on stderr or system console —
 fntmsg, 420
 extract gettext call strings — xgettext, 1710
 generate a formatted message catalog —
 gencat, 458
 permit or deny messages via write —
 mesg, 913
 retrieve text string from message database —
 gettext, 507
 mixerctl — audio mixer control, 916
 mkdir — make directories, 918
 mkmsgs — create message files for use by
 gettext, 920
 mkstr — create C error messages, 922
 modify the Access Control List (ACL) for a file
 or files — setfacl, 1385
 modular debugger — mdb, 872
 monitor process and LWP behavior using CPU
 performance counters — cputrack, 205

more — browse through a text file, 924
 mp — text to PDL (Page Description Language)
 pretty print filter, 931
 mpss.so.1 — shared object for setting preferred
 page size, 939
 msgfmt — create message object file, 942
 mt — manipulate magnetic tape, 948
 mv — move files, 951

N

nawk — pattern scanning and processing
 language, 954
 Actions, 954
 Arithmetic Functions, 954
 Expression Patterns, 954
 Expressions in nawk, 954
 Functions, 954
 Input/Output and General Functions, 954
 Output Statements, 954
 Pattern Ranges, 954
 Patterns, 954
 Regular Expressions, 954
 Special Patterns, 954
 String Functions, 954
 User-defined Functions, 954
 /usr/bin/nawk, 954
 /usr/xcu4/bin/awk, 954
 /usr/xpg4/bin/awk, 954
 Variables and Special Variables, 954
 NCA — the Network Cache and Accelerator
 (NCA), 975
 nca — the Network Cache and Accelerator
 (NCA), 975
 ncab2clf — convert binary log file to Common
 Log File format, 977
 ncakmod — start or stop the NCA kernel
 module, 979
 neqn — mathematical typesetting, 344
 netscape — start Netscape Communicator for
 Solaris, 980
 newform — change the format of a text file, 985
 newgrp — changes a user's group ID, 988
 newgrp — shell built-in function to allow new
 group permissions to the user, 988
 news — print news items, 990

- newsp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 801
- newtask — create new task or change task or project of running process, 991
- NFS, secure
 - decrypt and store secret key with keysevr — keylogin, 570
 - delete stored secret key with keysevr— keylogout, 572
- nice — invoke a command with an altered scheduling priority, 994
- nice, change process nice value — renice, 1266
- nice — invoke a command with an altered scheduling priority, csh Builtin, 994
- nis — a new version of the network information name service, 996
- NIS
 - change login password in — yppasswd, 1721
 - print the value of one or more keys from a NIS map — ypmatch, 1720
 - print values in a NIS database — ypcat, 1719
 - return name of NIS server or map master — ypwhich, 1722
- nis+ — a new version of the network information name service, 996
- NIS+ — a new version of the network information name service, 996
- NIS+
 - Authentication — nis+, 1003
 - Authorization — nis+, 1003
 - change access rights on a NIS+ object — nischmod, 1016
 - change password information — nispasswd, 1044
 - change the group owner of a NIS+ object — nischgrp, 1014
 - change the owner of a NIS+ object — nischown, 1019
 - change the time to live of a NIS+ object — nischttl, 1021
 - Concatenation Path — nis+, 999
 - create NIS+ directories — nismkdir, 1038
 - Directories and Domains — nis+, 1002
 - Directory Authorization — nis+, 1004
 - display NIS+ defaults — nisdefaults, 1023
- NIS+ (Continued)
 - display NIS+ error messages — niserror, 1026
 - display tables — niscat, 1011
 - Grammar — nis+, 998
 - Group Names — nis+, 1002
 - group administration — nisgrpadm, 1027
 - Indexed Names — nis+, 997
 - list the contents of a NIS+ directory — nisl, 1033
 - Name Expansion — nis+, 998
 - Namespaces — nis+, 1000
 - NIS+ Administrative Commands — nis+, 1007
 - NIS+ Directory Object — nis+, 996
 - NIS+ Files and Directories — nis+, 1009
 - NIS+ Group Object — nis+, 996
 - NIS+ Link Object — nis+, 997
 - NIS+ Programming API — nis+, 1008
 - NIS+ Table Object — nis+, 996
 - NIS+ User Commands — nis+, 1006
 - Principal Names — nis+, 1000
 - remove directories — nisrmdir, 1050
 - remove objects — nisrm, 1048
 - return the state of the NIS+ namespace using a conditional expression — nistest, 1058
 - Simple Names — nis+, 997
 - symbolically link NIS+ objects — nisln, 1031
 - Table Authorization — nis+, 1005
 - table administration tool — nistbladm, 1052
 - utilities for searching NIS+ tables — nismatch, nisgrep, 1035
- niscat — display NIS+ tables, 1011
- nischgrp — change the group owner of a NIS+ object, 1014
- nischmod — change access rights on a NIS+ object, 1016
- nischown — change the owner of a NIS+ object, 1019
- nischttl — change the time to live of a NIS+ object, 1021
- nisdefaults — display NIS+ defaults, 1023
- niserror — display NIS+ error messages, 1026
- nisgrep — utility for searching NIS+ tables, 1035
- nisgrpadm — NIS+ group administration command, 1027
- nisln — symbolically link NIS+ objects, 1031

nisl — list the contents of a NIS+ directory, 1033
 nismatch — utility for searching NIS+ tables, 1035
 nismkdir — create a NIS+ directory, 1038
 nism — remove NIS+ objects, 1048
 nismrmdir — remove a NIS+ directory, 1050
 nistbladm — administer NIS+ tables, 1052
 nistest — return the state of the NIS+ namespace using a conditional expression, 1058
 nl — number lines, 1060
 nm — print name list of an object file, 1064
 nohup — run a command immune to hangups, 1069
 notify — shell built-in functions to control process execution, 556
 notify user that volume requested is not in the CD-ROM or floppy drive — volmissing, 1679
 nroff — format documents for display or line-printer, 1073
 nroff utilities
 check nroff and troff files — checknr, 127
 eliminate .so's from nroff input — soelim, 1424
 filters reverse line-feeds from two-column nroff text — col, 173
 format tables — tbl, 1523
 remove nroff, troff, tbl and eqn constructs — deroff, 277

O

object archive, find ordering relation for an object or library archive — lorder, 753
 object files
 find printable strings — strings, 1472
 manipulate the comment section — mcs, 870
 print section sizes in bytes — size, 1418
 strip symbol table, debugging and line number information — strip, 1474
 octal dump, — od, 1076
 od — octal dump, 1076
 on — execute a command on a remote system, but with the local environment, 1082

onintr — shell built-in functions to respond to (hardware) signals, 1591
 online documentation system, — answerbook2, 42
 online reference pages — man, 863
 optisa — determine which variant instruction set is optimal to use, 1084

P

pack — compress files, 1085
 page — page through a text file, 924
 pagesize — display size or sizes of a page of memory, 1088
 pargs — print process arguments, environment variables, or auxiliary vector, 1089
 Pascal, create a tags file for use with ex and vi — ctags, 255
 passwd — change login password and password attributes, 1091
 password, change in NIS — yppasswd, 1721
 password file, edit — vipw, 1675
 passwords, change login password and password attributes — passwd, 1091
 paste — merge same lines of several files or subsequent lines of one file, 1098
 patch — apply changes to files, 1101
 File Name Determination, 1104
 Patch Application, 1104
 Patch File Format, 1103
 PATH variable — sh, 1396
 pathchk — check path names, 1106
 pathconv — search FMLI criteria for filename, 1109
 pathname
 prompts for a pathname — ckpath, 153
 provides error message for pathname — errpath, 153
 provides help message for pathname — helppath, 153
 validates pathname — valpath, 153
 pattern scanning and processing language — nawk, 954
 pax — portable archive interchange, 1111
 Modes of Operations, 1111
 Standard Error, 1117
 Standard Output, 1116

pcat — compress files, 1085
 pcred — proc tools, 1220
 pdp11 — get processor type truth value, 793
 performance monitoring
 display call-graph profile data — gprof, 512
 resource usage for a command —
 rusage, 1306
 time a command; report process data and
 system activity — timex, 1556
 perl — Practical Extraction and Report
 Language, 1120
 pfcsh — execute a command in a profile, 1127
 pfexec — execute a command in a profile, 1127
 pfiles — proc tools, 1220
 pfksh — execute a command in a profile, 1127
 pflags — proc tools, 1220
 pfsh — execute a command in a profile, 1127
 pg — files perusal filter for CRTs, 1128
 pgrep — find processes by name and other
 attributes, 1133
 pkginfo — display software package
 information, 1137
 pkgmk — produce an installable package, 1139
 pkgparam — display package parameter
 values, 1142
 pkgproto — generate prototype file entries for
 input to pkgmk command, 1144
 pkgtrans — translate package format, 1146
 pkill — signal processes by name and other
 attributes, 1133
 pldd — proc tools, 1220
 plimit — get or set the resource limits of
 running processes, 1148
 plot — graphics filters for plotters, 1150
 plotters, graphics filters — plot, 1150
 graphics filters — tplot, graphics filters, 1579
 pmap — display information about the address
 space of a process, 1152
 popd — shell built-in functions to change the
 current working directory, 118
 portable archive interchange — pax, 1111
 postplot — PostScript translator for plot(4B)
 graphics files, 1169
 postdaisy — PostScript translator for Diablo 630
 daisy-wheel files, 1159
 postdmd — PostScript translator for DMD
 bitmap files, 1161
 postio — serial interface for PostScript
 printers, 1163
 postmd — matrix display program for
 PostScript printers, 1166
 postprint — PostScript translator for text
 files, 1171
 postprocessors, troff for PostScript printers —
 dpost, 297
 postreverse — reverse the page order in a
 PostScript file, 1173
 PostScript
 matrix display program — postmd, 1166
 prepends host resident PostScript fonts to
 files — download, 295
 reverse the page order in a PostScript file —
 postreverse, 1173
 serial interface — postio, 1163
 translator for Diablo 630 daisy-wheel files —
 postdaisy, 1159
 translator for DMD bitmap files —
 postdmd, 1161
 translator for plot(4B) graphics files —
 postplot, 1169
 translator for Tektronix 4014 files —
 posttek, 1175
 translator for text files — postprint, 1171
 troff postprocessor for PostScript printers —
 dpost, 297
 PostScript translator for Diablo 630 daisy-wheel
 files — postdaisy, 1159
 PostScript translator for MD bitmap files —
 postdmd, 1161
 PostScript translator for Tektronix 4014 files —
 posttek, 1175
 PostScript translator for text files —
 postprint, 1171
 posttek — PostScript translator for Tektronix
 4014 files, 1175
 pr — print files, 1180
 Practical Extraction and Report Language —
 perl, 1120
 praliases — display system mail aliases, 1185
 prctl — get or set the resource controls of
 running processes, tasks, and projects, 1186
 preap — force a defunct process to be reaped by
 its parent, 1189
 prex — control tracing and manipulate probe
 points in a process or the kernel, 1191

- prime factors, obtain for a number — factor, 381
- print — shell built-in function to output characters to the screen or window, 1202
- print
 - formatted output — printf, 1204
 - print files — pr, 1180
- print process arguments, environment variables, or auxiliary vector — pargs, 1089
- print authorizations granted to a user — auths, 85
- print execution profiles for a user — profiles, 1227
- print files — lpr, 767
- print files, prepends host resident PostScript fonts to files — download, 295
- print project membership of user — projects, 1229
- print roles granted to a user — roles, 1286
- print services, print information about the status — lpstat, 773
- printenv — display environment variables, 1203
- printers
 - cancel requests — cancel, 111
 - control — lpc, 761
 - display queue — lpq, 765
 - print information about the status — lpstat, 773
 - remove jobs from queue — lprm, 771
 - send requests — lp, 754
 - test — lptest, 777
- printers, LP
 - disable, 340
 - enable, 340
- printf — print formatted output, 1204
- proc tools
 - pcred, 1220
 - pfiles, 1220
 - pflags, 1220
 - pldd, 1220
 - prun, 1220
 - psig, 1220
 - pstack, 1220
 - pstop, 1220
 - ptime, 1220
 - ptree, 1220
 - pwait, 1220
- proc tools (Continued)
 - pwdx, 1220
- process, running, change priority — renice, 1266
- process accounting
 - search and print files — acctcom, 30
 - time a command; report process data and system activity — timex, 1556
- process scheduler, display or set scheduling parameters of specified process(es) — priocntl, 1209
- process status, report — ps, 1230
- processes
 - display status — ps, 1239
 - get core images of running processes — gcore, 457
 - terminate a process by default — kill, 573
- processors, display type — mach, 792
- prof — display profile data, 1223
- profile, display call-graph — gprof, 512
- profiles — print execution profiles for a user, 1227
- programming languages
 - analyze and disperse compiler error messages — error, 349
 - C compiler — cc, 116
 - C preprocessor — cpp, 199
 - C program verifier — lint, 708
 - extract strings from C code — xstr, 1712
 - formats program in nice style using troff — vgrind, 1661
- programming tools
 - arbitrary precision arithmetic language — bc, 96
 - assembler — as, 62
 - create a tags file for use with ex and vi — ctags, 255
 - create C error messages — mkstr, 922
 - debugger — adb, 33
 - display call-graph profile data — gprof, 512
 - dump selected parts of an object file — dump, 305
 - find printable strings in an object or binary file — strings, 1472
 - install, 546
 - link editor — ld, 652
 - link-editor for object files — ld, 640
 - macro processor — m4, 787

programming tools (Continued)

- make — build programs, 828
- object code disassembler — dis, 289
- print name list of an object file — nm, 1064
- print section sizes in bytes of object files — size, 1418
- regular expression compile — regcmp, 1261
- resolve and remove ifdef'ed lines from C program source — unifdef, 1624
- resource usage for a command — rusage, 1306
- RPC protocol compiler — rpcgen, 1288
- Source Code Control System — sccs, 1317
- strip symbol table, debugging and line number information from an object file — strip, 1474
- touch — update last modified date of file, 1578

projects — print project membership of user, 1229

prun — proc tools, 1220

PS1 variable — sh, 1397

PS2 variable — sh, 1397

ps — display process status, 1239

psig — proc tools, 1220

pstack — proc tools, 1220

pstop — proc tools, 1220

ptime — proc tools, 1220

ptree — proc tools, 1220

pushd — shell built-in functions to change the current working directory, 118

pvs — display the internal versioning information of dynamic objects, 1242

pwait — proc tools, 1220

pwd — print working directory name, 1245

pwdx — proc tools, 1220

Q

queue, printer, display — lpq, 765

queues

- display the jobs queued to run at specified times — atq, 74
- remove jobs spooled by at or batch — atrm, 75

R

true — convert archives to random libraries, 1246

rcp — remote file copy, 1247

rdist — remote file distribution, 1249

read — shell built-in function to receive from standard input (keyboard), 1254

readfile, longline — (FMLI utility) reads file, gets longest line, 1257

readonly — shell built-in function to protect the value of the given variable from reassignment, 1258

reboot system without checking disks — fastboot, 382

red — text editor, 315

refer — expand and insert references from a bibliographic database, 1259

regcmp — regular expression compile, 1261

regenerate groups of programs — sysV-make, 1495

regenerate programs — make, 828

regex — (FMLI utility) match patterns against a string, 1263

registration, 1425

rehash — shell built-in functions to evaluate the internal hash table of the contents of directories, 527

reinit — (FMLI utility) changes the descriptors in the initialization file, 1265

relational database, — join, 563

reminder services

- calendar, 109
- mail notifier — biff, 105

remote shell — rsh, 1294

remote system

- connect — tip, 1558
- connect to — cu, 258
- execute a command on a remote system, but with the local environment — on, 1082
- file copy — rcp, 1247
- file distribution — rdist, 1249
- remote login — rlogin, 1270
- shell — rsh, 1294
- show status — rup, 1303, 1304
- spawn login — ct, 253
- system to system command execution — uux, 1650
- transfer files to and from — tftp, 1549

remote system (Continued)
 who is logged in on remote machines —
 rusers, 1308

removable rewritable media format utility —
 rmformat, 1276

rename the binding of an FNS name —
 fnrename, 433

renice — alter priority of running
 processes, 1266

report on the calls to a specific procedure —
 whocalls, 1700

report or filter out repeated lines in a file —
 uniq, 1626

reset — (FLMI utility) changes the entry in a
 field of a form to its default value, 1269

reset — reset terminal bits, 1604

reset terminal bits — reset, 1604

return — shell built-in functions to enable the
 execution of the shell to advance beyond its
 sequence of steps, 365

reverse page order, PostScript file —
 postreverse, 1173

reverse the page order in a PostScript file —
 postreverse, 1173

rksh — KornShell, restricted command and
 programming language, 585

rlogin — remote login, 1270

rm — remove files, 1273

rmdir — remove directories, 1273

rmformat — removable rewritable media
 format utility, 1276

roffbib — format and print bibliographic
 database, 1284

roles — print roles granted to a user, 1286

RPC
 display host status of remote machines —
 rup, 1304
 display status of network hosts — rup, 1303
 protocol compiler — rpcgen, 1288

RPC, secure
 decrypt and store secret key with keyserver —
 keylogin, 570
 delete stored secret key with keyserver —
 keylogout, 572

RPC Language, RPC protocol compiler —
 rpcgen, 1288

rpcgen — RPC protocol compiler, 1288

rpm2cpio — convert Red Hat Package (RPM) to
 cpio archive, 1293

rsh — remote shell, 1294

run — (FMLI utility) runs a program, 1298

run a command immune to hangups —
 nohup, 1069

runat — execute command in extended
 attribute name space, 1300

runtime linker for dynamic objects —
 ld.so.1, 681

rup — display status of network hosts (RPC
 version), 1303

rup — display status of network hosts, 1304

runtime — display status of local hosts, 1305

rusage — resource usage for a command, 1306

rusers — who is logged in on remote
 machines, 1308

rwwho — who is logged in on local
 machines, 1309

S

sag — system activity graph, 1310

sar — system activity reporter, 1312

SCCS, extract SCCS version information from a
 file — what, 1690

sccs-admin — create and administer SCCS
 history files, 1327

sccs-cdc — change the delta commentary of an
 SCCS delta, 1331

sccs-comb — combine deltas, 1333

sccs — Source Code Control System, 1317

SCCS commands
 admin — create and administer SCCS history
 files, 1327
 cdc — change the delta commentary of an
 SCCS delta, 1331
 comb — combine deltas, 1333
 delta — change the delta commentary of an
 SCCS delta, 1335
 get — retrieve a version of an SCCS
 file, 1338
 help — help regarding SCCS error or
 warning messages, 1344
 prt — display delta table information from
 an SCCS file, 1349

SCCS commands (Continued)

- rmdel — remove a delta from an SCCS file, 1352
- sact — show editing activity status of an SCCS file, 1353
- scs-prs — display selected portions of an SCCS history, 1345
- scsdiff — compare versions of SCCS file, 1354
- unget — unget SCCS file, 1355
- val — validate SCCS file, 1356

scs-delta — change the delta commentary of an SCCS delta, 1335

SCCS delta

- change commentary — scs-cdc, 1331
- combine — scs-comb, 1333
- create — delta, 1335
- remove — rmdel, 1352

SCCS delta table, print form an SCCS file — scs-prt, 1349

SCCS files

- compare versions — scs-scsdiff, 1354
- retrieve a version of a file — scs-get, 1338
- show editing activity status — scs-sact, 1353
- undo a previous get of an SCCS file — scs-unget, 1355
- validate — scs-val, 1356

scs-get — retrieve a version of an SCCS file, 1338

scs-help — help regarding SCCS error or warning messages, 1344

SCCS help, regarding SCCS error or warning messages — scs-help, 1344

SCCS history, display selected portions — scs-prs, 1345

SCCS history files, create and administer — scs-admin, 1327

scs-prs — display selected portions of an SCCS history, 1345

scs-prt — display delta table information from an SCCS file, 1349

scs-rmdel — remove delta from SCCS file, 1352

scs-sact — show editing activity status of an SCCS file, 1353

scs-scsdiff — compare versions of SCCS file, 1354

scs-unget — unget SCCS file, 1355

scs-val — validate SCCS file, 1356

scp — secure copy (remote file copy program), 1358

screen-oriented editor — vi, 1665

script — make script of terminal session, 1360

sdiff — print differences between two files side-by-side, 1361

search for FNS objects with specified attributes — fnsearch, 434

secure copy (remote file copy program) — scp, 1358

secure file transfer program — sftp, 1390

Secure Shell proxy for HTTP — ssh-http-proxy-connect, 1462

Secure Shell proxy for SOCKS5 — ssh-socks5-proxy-connect, 1467

sed — stream editor, 1363, 1371

- Functions, 1372
- sed Addresses, 1364
- sed Editing Commands, 1364
- sed Regular Expressions, 1364
- sed Scripts, 1371

select or reject lines common to two files — comm, 175

serial interface for PostScript printers — postio, 1163

set — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1377

set, unset — (FLMI utility) set and unset local or global environment variables, 1382

set environment for command invocation — env, 342

set or get limitations on the system resources available to the current shell and its descendents

- limit, 702
- ulimit, 702
- unlimit, 702

set process group ID — setpgrp, 1389

setcolor — (FMLI utility) redefine or create a color, 1384

setenv — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1377

setfacl — modify the Access Control List (ACL) for a file or files, 1385
 acl_entries Syntax, 1385
 setpggrp — set process group ID, 1389
 settime — change file access and modification times, 1574
 sftp — secure file transfer program, 1390
 sh — the standard shell command interpreter, 1393
 SHACCT variable — sh, 1397
 shared object for setting preferred page size — mpss.so.1, 939
 shell — (FMLI utility) run a command using shell, 1411
 SHELL variable — sh, 1397
 shell
 Korn shell — ksh, 585
 restricted Korn shell — rksh, 585
 shell command interpreter builtin-functions
 — alias, 36
 — bg, 556
 — break, 106
 — cd, 118
 — chdir, 118
 — continue, 106
 — dirs, 118
 — eval, 363
 — exit, 365
 — fc, 531
 — fg, 556
 — getopts, 501
 — glob, 511
 — hash, 527
 — hashstat, 527
 — history, 531
 — jobs, 556
 — kill, 573
 — let, 689
 — logout, 750
 — newgrp, 988
 — notify, 556
 — onintr, 1591
 — popd, 118
 — print, 1202
 — pushd, 118
 — read, 1254
 — readonly, 1258
 — rehash, 527
 shell command interpreter builtin-functions (Continued)
 — return, 365
 — set, 1377
 — setenv, 1377
 — shift, 1416
 — source, 363
 — stop, 556
 — suspend, 1493
 — times, 1555
 — trap, 1591
 — typeset, 1613
 — umask, 1617
 — unalias, 36
 — unhash, 527
 — unset, 1377
 — unsetenv, 1377
 — wait, 1685
 — whence, 1613
 shell programming
 echo arguments — echo, 309
 read one line from standard input and write to standard output — line, 707
 shell scripts
 display size or sizes of a page of memory — pagesize, 1088
 provide truth values — true, false, 1596
 shell variables, in Bourne shell, 1396
 shells
 C shell — csh, 224
 remote — rsh, 1294
 the job control shell command interpreter — jsh, 1393
 the standard shell command interpreter — sh, 1393
 shift — shell built-in function to traverse either a shell's argument list or a list of field-separated words, 1416
 show codeset table for the current locale — dumpcs, 308
 show current number of users in each FTP Server class — ftpcount, 455
 show current process information for each FTP Server user — ftpwho, 456
 shutdown — shut down multiuser operation, 1417
 sign on to the system — login, 742

Simple Mail Transfer Protocol, connection to remote mailserver — mconnect, 869

size — print section sizes in bytes of object files, 1418

sleep — suspend execution for an interval, 1420

smart2cfg — Compaq Smart-2 EISA/PCI and Smart-2SL PCI Array Controller ioctl utility, 1422

SMTP
See Simple Mail Transfer Protocol

soelim — eliminate .so's from nroff input, 1424

software package
display information — pkginfo, 1137
display parameter values — pkgparam, 1142
generate prototype file entries for input to pkgmk command — pkgproto, 1144
produce an installable package — pkgmk, 1139
translate package format — pkgtrans, 1146

Solaris user registration — solregis, 1425

solregis — Solaris user registration, 1425

sort, topological, items mentioned in input — tsort, 1609

sort — sort and/or merge files, 1428

sortbib — sort bibliographic database, 1435

sotruss — trace shared library procedure calls, 1437

source — shell built-in functions to execute other commands, 363

Source Code Control System
See SCCS

source files, locate — whereis, 1693

sparc — get processor type truth value, 793

spell — check spelling, 1439

spline — interpolate smooth curve, 1442

split files based on context — csplit, 250

split — split a file into pieces, 1443

srchtxt — display contents of, or search for a text string in, message data bases, 1445

ssh-agent — authentication agent, 1460

ssh-http-proxy-connect — Secure Shell proxy for HTTP, 1462

ssh-keygen — authentication key generation, 1464

ssh-socks5-proxy-connect — Secure Shell proxy for SOCKS5, 1467

standard output, replicate — tee, 1526

start Netscape Communicator for Solaris — netscape, 980

start or stop the NCA kernel module — ncakmod, 979

statistics, collected by sendmail — mailstats, 805

stop — shell built-in functions to control process execution, 556

strchg — change stream configuration, 1469

strconf — query stream configuration, 1469

stream editor — sed, 1363, 1371

STREAMS, change or query stream configuration — strchg, strconf, 1469

string
prompt for defined string answer — ckstr, 159
provide an error message for defined string answer — errstr, 159
provide an help message for defined string answer — helpstr, 159
validate a defined string answer — valstr, 159

strings — find printable strings in object or binary file, 1472

strip — strip symbol table, debugging and line number information from an object file, 1474

stty — set the options for a terminal, 1476

stty command, 1484

sum — print checksum and block count for a file, 1491

sum — sum and count blocks in file, 1492

sun — get processor type truth value, 793

SunOS/BSD Source Compatibility Package, — stty, 1484

SunOS/BSD Source Compatibility Package commands
— arch, 61
— basename, 95
— biff, 105
— cc, 116
— chown, 140
— df, 278
— du, 303
— echo, 313
— expr, 373
— fastboot, 382
— file, 391
— from, 443

SunOS/BSD Source Compatibility Package

commands (Continued)

- groups, 525
- grpck, 526
- hostid, 540
- hostname, 541
- install, 546
- ld, 652
- lint, 708
- ln, 727
- logger, 740
- lpc, 761
- lpq, 765
- lpr, 767
- lprm, 771
- lptest, 777
- ls, 784
- mach, 792
- mkstr, 922
- pagesize, 1088
- plot, 1150
- printenv, 1203
- ps, 1239
- rusage, 1306
- shutdown, 1417
- sum, 1492
- test, 1545
- tr, 1590
- tset, 1604
- users, 1634
- vipw, 1675
- whereis, 1693
- whoami, 1699

provide SunOS compatibility for Solaris mailbox format — mailcompat, 800

suspend — shell built-in function to halt the current shell, 1493

suspend execution of command, — sleep, 1420

symorder — update symbol table ordering, 1494

synchronize files and directories — filesync, 393

system to system copy — uucp, 1635

system activity

- graphical representation — sag, 1310
- reporter — sar, 1312

time a command; report process data and system activity — timex, 1556

system administration, — install, 546

system call and signals, trace — truss, 1597

system log, add entries — logger, 738

system name, print — uname, 1621

system to system command execution — uux, 1650

system uptime, display — uptime, 1633

sysV-make — maintain, update, and regenerate groups of programs, 1495

T

TAB characters, expand to SPACE characters, and vice versa — expand, unexpand, 367

tables, format for nroff or troff — tbl, 1523

tabs — set tabs on a terminal, 1502

tail — display last part of file, 1506

talk — talk to another user, 1509

tape

- backspace files — mt, 948
- backspace records — mt, 948
- erase — mt, 948
- forward space files — mt, 948
- forward space records — mt, 948
- get unit status — mt, 948
- place unit off-line — mt, 948
- retension — mt, 948
- rewind — mt, 948
- skip backward files — mt, 948
- skip backward records — mt, 948
- skip forward files — mt, 948
- skip forward records — mt, 948
- write EOF mark on — mt, 948

tape, magnetic

- copy, blocking preserved — tcopy, 1525
- manipulate — mt, 948
- scan — tcopy, 1525

tape archives, create — tar, 1512

tar — create tape archives, and add or extract files, 1512

tbl — format tables for nroff or troff, 1523

tbl, remove nroff, troff, tbl and eqn constructs — deroff, 277

tcopy — copy a magnetic tape, 1525

tee — replicate the standard output, 1526

telnet — user interface to a remote system using the TELNET protocol, 1527

- TELNET protocol, user interface to a remote system using the TELNET protocol — telnet, 1527
- terminal
 - set options — stty, 1476
 - set tabs — tabs, 1502
- terminal screen, — clear, 170
- terminal session, make script— script, 1360
- terminals
 - get name — tty, 1611
 - initialize a terminal or query terminfo database — tput, 1580
 - reset bits — reset, 1604
 - set characteristics — tset, 1604
 - set characteristics — stty, 1484
- terminate a process by default — kill, 573
- terminfo database, initialize a terminal or query terminfo database — tput, 1580
- test — (FMLI utility) evaluates the expression expression, 1547
- test — evaluate condition(s), 1537
- test — condition evaluation, 1545
- text editing
 - screen-oriented (visual) display editor based on ex — vi, 1665
 - sed — stream editor, 1371
 - stream editor — sed, 1363
- text editor
 - ed, 315
 - edit, 327
 - ex, 353
- text files
 - browse or page through a text file — more, page, 924
 - change format — newform, 985
- text formatter, format documents for display or line-printer — nroff, 1073
- text processing utilities
 - check spelling — spell, 1439
 - concatenate and display files — cat, 113
 - display last part of file — tail, 1506
 - pattern scanning and processing language — awk, 87
 - search a file for a pattern — grep, 519
 - search a file for a pattern using full regular expressions — egrep, 331
 - search file for fixed-character string — fgrep, 387
- text processing utilities (Continued)
 - sort and/or merge files — sort, 1428
 - split a file into pieces — split, 1443
 - translate characters — tr, 1585, 1590
 - underline text — ul, 1616
- text retrieval tools
 - create message files for use by gettxt — mkmsgs, 920
 - retrieve text string from message database — gettxt, 509
- text to PDL (Page Description Language) pretty print filter — mp, 931
- tftp — trivial file transfer program, 1549
- the Network Cache and Accelerator (NCA) — NCA, 975
- the Network Cache and Accelerator (NCA) — nca, 975
- tilde escape commands for mail, — mailx, 818
- time — time a simple command, 1552
- time
 - prompts for time — cktime, 164
 - provides error message for time — errtime, 164
 - provides help message for time — helptime, 164
 - validates time — valtime, 164
- time a simple command — time, 1552
- timed event services
 - display the jobs queued to run at specified times — atq, 74
 - reminder service — calendar, 109
 - remove jobs spooled by at or batch — atrm, 75
 - user crontab file — crontab, 219
- timemanp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 801
- times — shell built-in function to report time usages of the current shell, 1555
- timesysp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 801
- timex — time a command; report process data and system activity, 1556
- tip — connect to remote system, 1558
- tnfdump — convert binary TNF file to ASCII, 1567

tnfextract — extract kernel probes output into a trace file, 1572

touch — change file access and modification times, 1574, 1612
 settime, 1575
 touch, 1574

touch — update last modified date of file, 1578

tplot — graphics filters for plotters, 1579

tput — initialize a terminal or query terminfo database, 1580

tr — translate characters, 1585, 1590

trace function calls, trace application function calls to Solaris shared libraries —
 apptrace, 50

trace shared library procedure calls —
 sotruss, 1437

translate characters — tr, 1585, 1590

translates exportfs options to share/unshare commands — exportfs, 369

trap — shell built-in functions to respond to (hardware) signals, 1591

Trivial File Transfer Protocol
See TFTP

troff — typeset or format documents, 1593

troff utilities
 check nroff and troff files — checknr, 127
 eliminate .so's from nroff input —
 soelim, 1424
 filters reverse line-feeds from two-column nroff text — col, 173
 format tables — tbl, 1523
 formats program code — vgrind, 1661
 postprocessor for PostScript printers —
 dpost, 297
 remove nroff, troff, tbl and eqn constructs —
 deroff, 277

true — provide truth values, 1596

truss — trace system calls and signals, 1597

tset — set terminal characteristics, 1604

tsort — topological sort of items mentioned in input, 1609

ttl — time to live value, nischtll, 1021

tty, set characteristics — stty, 1484

tty, set characteristics — tset, 1604

tty, set options — stty, 1476

tty — get the name of the terminal, 1611

typeset — shell built-in functions to set/get attributes and values for shell variables and functions, 1613

typeset documents — troff, 1593

U

u370 — get processor type truth value, 793

u3b — get processor type truth value, 793

u3b2 — get processor type truth value, 793

u3b5 — get processor type truth value, 793

u3b15 — get processor type truth value, 793

ucblinks — adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices, 1615

ul — underline text, 1616

ulimit — set or get limitations on the system resources available to the current shell and its descendents, 702

umask — shell built-in function to restrict read/write/execute permissions, 1617

unalias — shell built-in functions to create your own pseudonym or shorthand for a command or series of commands, 36

uname — print name of current system, 1621

unbind the reference from an FNS name —
 funbind, 440

uncompress — uncompress files, 180

underline text — ul, 1616

unexpand — unexpand SPACE characters to TAB characters, 367

unhash — shell built-in functions to evaluate the internal hash table of the contents of directories, 527

unifdef — resolve and remove ifdef'ed lines from C program source, 1624

uniq — report or filter out repeated lines in a file, 1626

units — converts quantities expressed in standard scales to other scales, 1629

UNIX, convert text file from DOS format to ISO format — dos2unix, 293

unix2dos — convert text file from ISO format to DOS format, 1631

UNIX-to-UNIX commands
 uucp — uucp, 1635
 uulog — uucp, 1635

UNIX-to-UNIX commands (Continued)

uuname — uucp, 1635
unlimit — set or get limitations on the system resources available to the current shell and its descendents, 702
unpack — expand compressed files, 1085
unset — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1377
unsetenv — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1377
update and examine attributes associated with FNS named object — fnattr, 425
update groups of programs — sysV-make, 1495
update last modified date of file — touch, 1578
update programs — make, 828
uptime — show how long the system has been up, 1633
user ID, change user IDs of files — chown, 140
user IDs
 display a list of all valid user names — dispuid, 292
 prompts for user ID — ckuid, 166
 provides error message for user ID — erruid, 166
 provides help message for user ID — helpuid, 166
 validates user ID — valuid, 166
users
 display effective name — whoami, 1699
 display group membership — groups, 524
 display information about local and remote users — finger, 407
 get the name of the user running the process — logname, 749
 list user login information — listusers, 712
 talk to another user — talk, 1509
 who is logged in, and what are they doing — w, 1683
 who is logged in on local machines — rwho, 1309
 who is logged in on remote machines — rusers, 1308
 who is on the system — who, 1696
 write to another user — write, 1702

users, network, Internet user name directory service — whois, 1701
users — display users on system, 1634
uucp — UNIX-to-UNIX copy, 1635
uucp
 log — uulog, 1635
 uucp status inquiry — uustat, 1643
uudecode — decode binary file, 1639
uuencode — encode binary file, 1639
uuglist — print list of service grades available, 1642
uulog — UUCP log, 1635
uuname — UUCP list of names, 1635
uustat — uucp status inquiry, 1643
uux — system to system command execution, 1650

V

vacation — automatic mail replies, 1654
vax — get processor type truth value, 793
version control, — vc, 1657
vgrind — formats program in nice style using troff, 1661
vi — screen-oriented (visual) display editor based on ex, 1665
vipw — edit password file, 1675
volcancel — cancel user's request for removable media that is not currently in drive, 1676
volcheck — check for media in a drive, 1677
volmissing — notify user that volume requested is not in the CD-ROM or floppy drive, 1679
volrmount — call rmmount to mount or unmount media, 1680
Volume Management
 cancel user's request for removable media that is not currently in drive — volcancel, 1676
 check for media in a drive — volcheck, 1677
 missing volume notification — volmissing, 1679
vsig — synchronize a co-process with the controlling FMLI application, 1682

W

w — display information about currently logged-in users, 1683

w — who is logged in, and what are they doing, 1683

wait — shell built-in function to wait for other jobs or processes, 1685

wc — display a count of lines, words and characters in a file, 1688

what — extract SCCS version information from a file, 1690

whatis — describe command, 1692

whence — shell built-in functions to set/get attributes and values for shell variables and functions, 1613

whereis — locate the binary, source and manual page files for a command, 1693

which — locate a command; display its pathname or alias, 1695

who is logged in — w, 1683

who — who is on the system, 1696

whoami — display effective user name, 1699

whocalls — report on the calls to a specific procedure, 1700

whois — Internet user name directory service, 1701

write — write to another user, 1702

write file checksums and sizes — cksum, 162

X

xargs — construct argument lists and invoke utility, 1705

xgettext — extract gettext call strings, 1710

xstr — extract strings from C code, 1712

Y

yacc — yet another compiler-compiler, 1714

yacc, create a tags file for use with ex and vi — ctags, 255

yes — generate repetitive affirmative output, 1718

yes/no answer
prompts for yes/no answer — ckyorn, 168

yes/no answer (Continued)

provides error message for yes/no answer — erryorn, 168

provides help message for yes/no answer — helpyorn, 168

validates yes/no answer — valyorn, 168

yet another compiler-compiler — yacc, 1714

ypcat — print values in a NIS database, 1719

ypmatch — print the value of one or more keys from a NIS map, 1720

yppasswd — change your network password in the NIS database, 1721

ypwhich — return name of NIS server or map master, 1722

Z

zcat — displays uncompressed files but leaves compressed files intact, 180
