| <b>SYNOPSIS</b>    | <pre> /usr/bin/ksh [± abCefhikmnoprstuvx] [± o option...] [arg...]  /usr/bin/ksh -c [± abCefhikmnoprstuvx] [± o option...] command_string [command_name [arg...]]  /usr/xpg4/bin/sh [± abCefhikmnoprstuvx] [± o option...] [arg...]  /usr/xpg4/bin/sh -c [± abCefhikmnoprstuvx] [± o option...] command_string [command_name [arg...]]  /usr/bin/rksh [± abCefhikmnoprstuvx] [± o option...] [arg...]  /usr/bin/rksh -c [± abCefhikmnoprstuvx] [± o option...] command_string [command_name [arg...]] </pre>                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The <code>/usr/xpg4/bin/sh</code> utility is a standards compliant shell. This utility provides all the functionality of <code>/usr/bin/ksh</code>, except in cases discussed below where differences in behavior exist. See Arithmetic Expansions section for details.</p> <p><code>/usr/bin/ksh</code> is a command and programming language that executes commands read from a terminal or a file. <code>rksh</code> is a restricted version of the command interpreter <code>ksh</code>; it is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. See <code>Invocation</code> below for the meaning of arguments to the shell.</p>                                                                                                                                                                            |
| <b>Definitions</b> | <p>A <i>metacharacter</i> is one of the following characters:</p> <pre> ; &amp; ( )   &lt; &gt; NEWLINE SPACE TAB </pre> <p>A <i>blank</i> is a TAB or a SPACE. An <i>identifier</i> is a sequence of letters, digits, or underscores starting with a letter or underscore. Identifiers are used as names for <i>functions</i> and <i>variables</i>. A <i>word</i> is a sequence of <i>characters</i> separated by one or more non-quoted <i>metacharacters</i>.</p> <p>A <i>command</i> is a sequence of characters in the syntax of the shell language. The shell reads each command and carries out the desired action either directly or by invoking separate utilities. A <i>special-command</i> is a command that is carried out by the shell without creating a separate process. Except for documented side effects, most special commands can be implemented as separate utilities.</p> |
| <b>Commands</b>    | <p>A <i>simple-command</i> is a sequence of blank-separated words which may be preceded by a variable assignment list. (See <code>Environment</code> below.) The first word specifies the name of the command to be executed. Except as specified below, the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see <code>exec(2)</code>). The <i>value</i> of a simple-command is its exit status if it terminates normally. If it terminates abnormally due to receipt of a signal, the <i>value</i> is the signal number plus 128. See <code>signal(3HEAD)</code> for a list of signal values. Obviously, normal exit status values 129 to 255 cannot be distinguished from abnormal exit caused by receiving signal numbers 1 to 127.</p>                                                                                             |

ksh(1)

A *pipeline* is a sequence of one or more *commands* separated by `|`. The standard output of each command but the last is connected by a `pipe(2)` to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate. The exit status of a pipeline is the exit status of the last command.

A *list* is a sequence of one or more *pipelines* separated by `;`, `&`, `&&`, or `| |`, and optionally terminated by `;`, `&`, or `| &`. Of these five symbols, `;`, `&`, and `| &` have equal precedence, which is lower than that of `&&` and `| |`. The symbols `&&` and `| |` also have equal precedence. A semicolon (`;`) causes sequential execution of the preceding pipeline; an ampersand (`&`) causes asynchronous execution of the preceding pipeline (that is, the shell does *not* wait for that pipeline to finish). The symbol `| &` causes asynchronous execution of the preceding command or pipeline with a two-way pipe established to the parent shell.

The standard input and output of the spawned command can be written to and read from by the parent shell using the `-p` option of the special commands `read` and `print` described in `Special Commands`. The symbol `&&` (`| |`) causes the *list* following it to be executed only if the preceding pipeline returns 0 (or a non-zero) value. An arbitrary number of new-lines may appear in a *list*, instead of a semicolon, to delimit a command.

A *command* is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command.

`for identifier [ in word ... ] ; do list ; done`

Each time a `for` command is executed, *identifier* is set to the next *word* taken from the `in word` list. If `in word ...` is omitted, then the `for` command executes the `do list` once for each positional parameter that is set (see `Parameter Substitution` below). Execution ends when there are no more words in the list.

`select identifier [ in word ... ] ; do list ; done`

A `select` command prints to standard error (file descriptor 2), the set of *words*, each preceded by a number. If `in word ...` is omitted, then the positional parameters are used instead (see `Parameter Substitution` below). The PS3 prompt is printed and a line is read from the standard input. If this line consists of the number of one of the listed *words*, then the value of the variable *identifier* is set to the *word* corresponding to this number. If this line is empty the selection list is printed again. Otherwise the value of the variable *identifier* is set to NULL. (See `Blank Interpretation` about NULL). The contents of the line read from standard input is saved in the shell variable `REPLY`. The *list* is executed for each selection until a `break` or EOF is encountered. If the `REPLY` variable is set to NULL by the execution of *list*, then the selection list is printed before displaying the PS3 prompt for the next selection.

`case word in [ pattern [ | pattern ] ) list ; ; ] ... esac`

A `case` command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation (see `File Name Generation` below).

```
if list ; then list ; [elif list ; then list ; ...] [else list ;] fi
```

The *list* following *if* is executed and, if it returns an exit status of 0, the *list* following the first *then* is executed. Otherwise, the *list* following *elif* is executed and, if its value is 0, the *list* following the next *then* is executed. Failing that, the *else list* is executed. If no *else list* or *then list* is executed, then the *if* command returns 0 exit status.

```
while list ; do list ; done
```

```
until list ; do list ; done
```

A *while* command repeatedly executes the *while list* and, if the exit status of the last command in the *list* is 0, executes the *do list*; otherwise the loop terminates. If no commands in the *do list* are executed, then the *while* command returns 0 exit status. *until* may be used in place of *while* to negate the loop termination test.

```
(list)
```

Execute *list* in a separate environment. Notice that if two adjacent open parentheses are needed for nesting, a space must be inserted to avoid arithmetic evaluation as described below.

```
{list}
```

*list* is simply executed. Notice that, unlike the metacharacters ( and ), { and } are *reserved words* and must occur at the beginning of a line or after a ; in order to be recognized.

```
[expression]
```

Evaluates *expression* and returns 0 exit status when *expression* is true. See Conditional Expressions below, for a description of *expression*.

```
function identifier { list ; }
```

```
identifier () { list ; }
```

Define a function which is referenced by *identifier*. The body of the function is the *list* of commands between { and }. (See Functions below).

```
time pipeline
```

The *pipeline* is executed and the elapsed time as well as the user and system time are printed to standard error.

The following reserved words are only recognized as the first word of a command and when not quoted:

```
! if then else elif fi case
esac for while until do done { }
function select time [[]]
```

**Comments** A word beginning with # causes that word and all the following characters up to a new-line to be ignored.

**Aliasing** The first word of each command is replaced by the text of an alias if an alias for this word has been defined. An alias name consists of any number of characters excluding metacharacters, quoting characters, file expansion characters, parameter and command substitution characters, and =. The replacement string can contain any valid shell script including the metacharacters listed above. The first word of each command

ksh(1)

in the replaced text, other than any that are in the process of being replaced, will be tested for aliases. If the last character of the alias value is a *blank* then the word following the alias will also be checked for alias substitution. Aliases can be used to redefine special builtin commands but cannot be used to redefine the reserved words listed above. Aliases can be created, listed, and exported with the `alias` command and can be removed with the `unalias` command. Exported aliases remain in effect for scripts invoked by name, but must be reinitialized for separate invocations of the shell (see *Invocation* below). To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word will be replaced by the value of the alias; otherwise, it will not be replaced.

Aliasing is performed when scripts are read, not while they are executed. Therefore, for an alias to take effect, the `alias` definition command has to be executed before the command which references the alias is read.

Aliases are frequently used as a short hand for full path names. An option to the aliasing facility allows the value of the alias to be automatically set to the full pathname of the corresponding command. These aliases are called *tracked* aliases. The value of a *tracked* alias is defined the first time the corresponding command is looked up and becomes undefined each time the `PATH` variable is reset. These aliases remain *tracked* so that the next subsequent reference will redefine the value. Several tracked aliases are compiled into the shell. The `-h` option of the `set` command makes each referenced command name into a tracked alias.

The following *exported aliases* are compiled into (and built-in to) the shell but can be unset or redefined:

```
autoload='typeset -fu'
false='let 0'
functions='typeset -f'
hash='alias -t'
history='fc -l'
integer='typeset -i'
nohup='nohup '
r='fc -e -'
true=':'
type='whence -v'
```

An example concerning trailing blank characters and reserved words follows. If the user types:

```
$ alias foo="/bin/ls "
$ alias while="/"
```

the effect of executing:

```
$ while true
> do
> echo "Hello, World"
> done
```

is a never-ending sequence of `Hello, World` strings to the screen. However, if the user types:

```
$ foo while
```

the result will be an `ls` listing of `/`. Since the alias substitution for `foo` ends in a space character, the next word is checked for alias substitution. The next word, `while`, has also been aliased, so it is substituted as well. Since it is not in the proper position as a command word, it is not recognized as a reserved word.

If the user types:

```
$ foo; while
```

`while` retains its normal reserved-word properties.

### Tilde Substitution

After alias substitution is performed, each word is checked to see if it begins with an unquoted `~`. If it does, then the word up to a `/` is checked to see if it matches a user name. If a match is found, the `~` and the matched login name are replaced by the login directory of the matched user. This is called a *tilde* substitution. If no match is found, the original text is left unchanged. A `~` by itself, or in front of a `/`, is replaced by `$HOME`. A `~` followed by a `+` or `-` is replaced by `$PWD` and `$OLDPWD`, respectively.

In addition, *tilde* substitution is attempted when the value of a *variable assignment* begins with a `~`.

### Tilde Expansion

A *tilde-prefix* consists of an unquoted tilde character at the beginning of a word, followed by all of the characters preceding the first unquoted slash in the word, or all the characters in the word if there is no slash. In an assignment, multiple tilde-prefixes can be used: at the beginning of the word (that is, following the equal sign of the assignment), following any unquoted colon or both. A tilde-prefix in an assignment is terminated by the first unquoted colon or slash. If none of the characters in the tilde-prefix are quoted, the characters in the tilde-prefix following the tilde are treated as a possible login name from the user database.

A portable login name cannot contain characters outside the set given in the description of the `LOGNAME` environment variable. If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix will be replaced by the value of the variable `HOME`. If `HOME` is unset, the results are unspecified. Otherwise, the tilde-prefix will be replaced by a pathname of the home directory associated with the login name obtained using the `getpwnam` function. If the system does not recognize the login name, the results are undefined.

Tilde expansion generally occurs only at the beginning of words, but an exception based on historical practice has been included:

```
PATH=/posix/bin:~dgk/bin
```

is eligible for tilde expansion because tilde follows a colon and none of the relevant characters is quoted. Consideration was given to prohibiting this behavior because any of the following are reasonable substitutes:

```
PATH=$(printf %s ~karels/bin : ~bostic/bin)
for Dir in ~maat/bin ~srb/bin .
do
```

ksh(1)

```
PATH=${PATH:+$PATH:}$Dir
done
```

With the first command, explicit colons are used for each directory. In all cases, the shell performs tilde expansion on each directory because all are separate words to the shell.

Notice that expressions in operands such as:

```
make -k mumble LIBDIR=~chet/lib
```

do not qualify as shell variable assignments and tilde expansion is not performed (unless the command does so itself, which `make` does not).

The special sequence `$~` has been designated for future implementations to evaluate as a means of forcing tilde expansion in any word.

Because of the requirement that the word not be quoted, the following are not equivalent; only the last will cause tilde expansion:

```
\~h1j/ ~h1j/ ~"h1j"/ ~h1j\ ~h1j/
```

The results of giving tilde with an unknown login name are undefined because the KornShell `~+` and `~-` constructs make use of this condition, but, in general it is an error to give an incorrect login name with tilde. The results of having `HOME` unset are unspecified because some historical shells treat this as an error.

### Command Substitution

The standard output from a *command* enclosed in parenthesis preceded by a dollar sign (that is, `$(command)`) or a pair of grave accents (``command``) may be used as part or all of a word. Trailing new-lines are removed. In the second (archaic) form, the string between the quotes is processed for special quoting characters before the command is executed. (See `Quoting` below.) The command substitution `$(cat file)` can be replaced by the equivalent but faster `$(<file)`. Command substitution of most special commands that do not perform input/output redirection are carried out without creating a separate process.

Command substitution allows the output of a command to be substituted in place of the command name itself. Command substitution occurs when the command is enclosed as follows:

```
$(command)
```

or (backquoted version):

```
`command`
```

The shell will expand the command substitution by executing *command* in a subshell environment and replacing the command substitution (the text of *command* plus the enclosing `$( )` or backquotes) with the standard output of the command, removing sequences of one or more newline characters at the end of the substitution. Embedded

newline characters before the end of the output will not be removed; however, they may be treated as field delimiters and eliminated during field splitting, depending on the value of IFS and quoting that is in effect.

Within the backquoted style of command substitution, backslash shall retain its literal meaning, except when followed by:

\$ ` \

(dollar-sign, backquote, backslash). The search for the matching backquote is satisfied by the first backquote found without a preceding backslash. During this search, if a non-escaped backquote is encountered within a shell comment, a here-document, an embedded command substitution of the  $\$(command)$  form, or a quoted string, undefined results occur. A single- or double-quoted string that begins, but does not end, within the `' . . .'` sequence produces undefined results.

With the  $\$(command)$  form, all characters following the open parenthesis to the matching closing parenthesis constitute the *command*. Any valid shell script can be used for *command*, except:

- A script consisting solely of redirections produces unspecified results.
- See the restriction on single subshells described below.

The results of command substitution will not be field splitting and pathname expansion processed for further tilde expansion, parameter expansion, command substitution or arithmetic expansion. If a command substitution occurs inside double-quotes, it will not be performed on the results of the substitution.

Command substitution can be nested. To specify nesting within the backquoted version, the application must precede the inner backquotes with backslashes; for example:

```
``command``
```

The  $\$( )$  form of command substitution solves a problem of inconsistent behavior when using backquotes. For example:

| Command                           | Output            |
|-----------------------------------|-------------------|
| <code>echo `\\$x`</code>          | <code>\\$x</code> |
| <code>echo 'echo `\\$x`'</code>   | <code>\$x</code>  |
| <code>echo \$(echo `\\$x`)</code> | <code>\\$x</code> |

Additionally, the backquoted syntax has historical restrictions on the contents of the embedded command. While the new  $\$( )$  form can process any kind of valid embedded script, the backquoted form cannot handle some valid scripts that include backquotes. For example, these otherwise valid embedded scripts do not work in the left column, but do work on the right:

ksh(1)

|                             |                             |
|-----------------------------|-----------------------------|
| echo `                      | echo \$(                    |
| cat <<eof                   | cat <<eof                   |
| a here-doc with `           | a here-doc with )           |
| eof                         | eof                         |
| `                           | )                           |
| echo `                      | echo \$(                    |
| echo abc # a comment with ` | echo abc # a comment with ) |
| `                           | )                           |
| echo `                      | echo \$(                    |
| echo '''                    | echo `)`                    |
| `                           | )                           |

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

If the command substitution consists of a single subshell, such as:

```
$(command)
```

a portable application must separate the `$(` and `(` into two tokens (that is, separate them with white space). This is required to avoid any ambiguities with arithmetic expansion.

### Arithmetic Expansion

An arithmetic expression enclosed in double parentheses preceded by a dollar sign (`$(arithmetic-expression)`) is replaced by the value of the arithmetic expression within the double parenthesis. Arithmetic expansion provides a mechanism for evaluating an arithmetic expression and substituting its value. The format for arithmetic expansion is as follows:

```
$(expression)
```

The expression is treated as if it were in double-quotes, except that a double-quote inside the expression is not treated specially. The shell will expand all tokens in the expression for parameter expansion, command substitution and quote removal.

Next, the shell will treat this as an arithmetic expression and substitute the value of the expression. The arithmetic expression will be processed according to the rules of the ISO C with the following exceptions:

- Only integer arithmetic is required.
- The `sizeof()` operator and the prefix and postfix `++` and `--` operators are not required.

- Selection, iteration, and jump statements are not supported.
- `/usr/bin/ksh` and `/usr/bin/rksh` treat prefix 0 through 9 as decimal constants. See the examples below.

| Command                           | Result in <code>/bin/ksh</code> | Result in <code>/usr/xpg4/bin/sh</code> |
|-----------------------------------|---------------------------------|-----------------------------------------|
| <code>echo \$((010+10 ))</code>   | 20                              | 18                                      |
| <code>echo \$((010+10 ))</code>   | 29                              | error                                   |
| <code>[ 10 -le \$((011)) ]</code> | true                            | false                                   |

As an extension, the shell may recognize arithmetic expressions beyond those listed. If the expression is invalid, the expansion will fail and the shell will write a message to standard error indicating the failure.

A simple example using arithmetic expansion:

```
repeat a command 100 times
x=100
while [$x -gt 0]
do
 command
 x=$((x-1))
done
```

### Process Substitution

This feature is available in SunOS and only on versions of the UNIX operating system that support the `/dev/fd` directory for naming open files. Each command argument of the form `<(list)` or `>(list)` will run process *list* asynchronously connected to some file in `/dev/fd`. The name of this file will become the argument to the command. If the form with `>` is selected, then writing on this file will provide input for *list*. If `<` is used, then the file passed as an argument will contain the output of the *list* process. For example:

```
paste <(cut -f1 file1) <(cut -f3 file2) | tee >(process1) >(process2)
```

`cut`s fields 1 and 3 from the files *file1* and *file2*, respectively, pastes the results together, and sends it to the processes *process1* and *process2*, as well as putting it onto the standard output. Notice that the file, which is passed as an argument to the command, is a UNIX pipe(2) so programs that expect to `lseek(2)` on the file will not work.

### Parameter Substitution

A *parameter* is an *identifier*, one or more digits, or any of the characters `*`, `@`, `#`, `?`, `-`, `$`, and `!`. A *variable* (a *parameter* denoted by an *identifier*) has a *value* and zero or more *attributes*. *variables* can be assigned *values* and *attributes* by using the `typeset` special command. The attributes supported by the shell are described later with the `typeset` special command. Exported variables pass values and attributes to the environment.

ksh(1)

The shell supports a one-dimensional array facility. An element of an array variable is referenced by a *subscript*. A *subscript* is denoted by a `[`, followed by an *arithmetic expression* (see Arithmetic Evaluation below) followed by a `]`. To assign values to an array, use `set -A name value . . .`. The *value* of all subscripts must be in the range of 0 through 4095. Arrays need not be declared. Any reference to a variable with a valid subscript is legal and an array will be created if necessary. Referencing an array without a subscript is equivalent to referencing the element 0. If an array *identifier* with subscript `*` or `@` is used, then the value for each of the elements is substituted (separated by a field separator character).

The *value* of a *variable* may be assigned by writing:

```
name=value [name=value] . . .
```

If the integer attribute, `-i`, is set for *name*, the *value* is subject to arithmetic evaluation as described below.

Positional parameters, parameters denoted by a number, may be assigned values with the `set` special command. Parameter `$0` is set from argument zero when the shell is invoked. If *parameter* is one or more digits then it is a positional parameter. A positional parameter of more than one digit must be enclosed in braces.

## Parameter Expansion

The format for parameter expansion is as follows:

```
${expression}
```

where *expression* consists of all characters until the matching `}`. Any `}` escaped by a backslash or within a quoted string, and characters in embedded arithmetic expansions, command substitutions and variable expansions, are not examined in determining the matching `}`.

The simplest form for parameter expansion is:

```
${parameter}
```

The value, if any, of *parameter* will be substituted.

The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when *parameter* is followed by a character that could be interpreted as part of the name. The matching closing brace will be determined by counting brace levels, skipping over enclosed quoted strings and command substitutions.

If the parameter name or symbol is not enclosed in braces, the expansion will use the longest valid name whether or not the symbol represented by that name exists. When the shell is scanning its input to determine the boundaries of a name, it is not bound by its knowledge of what names are already defined. For example, if `F` is a defined shell variable, the command:

```
echo $Fred
```

does not echo the value of `$F` followed by `red`; it selects the longest possible valid name, `Fred`, which in this case might be unset.

If a parameter expansion occurs inside double-quotes:

- Pathname expansion will not be performed on the results of the expansion.
- Field splitting will not be performed on the results of the expansion, with the exception of `@`.

In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of *word* is needed (based on the state of *parameter*, as described below), *word* will be subjected to tilde expansion, parameter expansion, command substitution and arithmetic expansion. If *word* is not needed, it will not be expanded. The `}` character that delimits the following parameter expansion modifications is determined as described previously in this section and in `dquote`. (For example, `${foo-bar}xyz` would result in the expansion of `foo` followed by the string `xyz` if `foo` is set, else the string `barxyz`).

|                                  |                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\${parameter:-word}</code> | Use Default Values . If <i>parameter</i> is unset or null, the expansion of <i>word</i> will be substituted; otherwise, the value of <i>parameter</i> will be substituted.                                                                                                                                                                                    |
| <code>\${parameter:=word}</code> | Assign Default Values . If <i>parameter</i> is unset or null, the expansion of <i>word</i> will be assigned to <i>parameter</i> . In all cases, the final value of <i>parameter</i> will be substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.                                                        |
| <code>\${parameter:?word}</code> | Indicate Error if Null or Unset . If <i>parameter</i> is unset or null, the expansion of <i>word</i> (or a message indicating it is unset if <i>word</i> is omitted) will be written to standard error and the shell will exit with a non-zero exit status. Otherwise, the value of <i>parameter</i> will be substituted. An interactive shell need not exit. |
| <code>\${parameter:+word}</code> | Use Alternative Value . If <i>parameter</i> is unset or null, null will be substituted. Otherwise, the expansion of <i>word</i> will be substituted.                                                                                                                                                                                                          |

In the parameter expansions shown previously, use of the colon in the format results in a test for a parameter that is unset or null. Omission of the colon results in a test for a parameter that is only unset. The following table summarizes the effect of the colon:

ksh(1)

|                       | parameter set and not null  | parameter set and null      | parameter unset        |
|-----------------------|-----------------------------|-----------------------------|------------------------|
| $\${parameter:-word}$ | substitute <i>parameter</i> | substitute <i>word</i>      | substitute <i>word</i> |
| $\${parameter-word}$  | substitute <i>parameter</i> | substitute null             | substitute <i>word</i> |
| $\${parameter:=word}$ | substitute <i>parameter</i> | assign <i>word</i>          | assign <i>word</i>     |
| $\${parameter=word}$  | substitute <i>parameter</i> | substitute <i>parameter</i> | assign null            |
| $\${parameter:?word}$ | substitute <i>parameter</i> | error, exit                 | error, exit            |
| $\${parameter?word}$  | substitute <i>parameter</i> | substitute null             | error, exit            |
| $\${parameter:+word}$ | substitute <i>word</i>      | substitute null             | substitute null        |
| $\${parameter+word}$  | substitute <i>word</i>      | substitute <i>word</i>      | substitute null        |

In all cases shown with “substitute”, the expression is replaced with the value shown. In all cases shown with “assign” *parameter* is assigned that value, which also replaces the expression.

$\{\#parameter\}$  String Length. The length in characters of the value of *parameter*. If *parameter* is \* or @, then all the positional parameters, starting with \$1, are substituted (separated by a field separator character).

The following four varieties of parameter expansion provide for substring processing. In each case, pattern matching notation (see `patmat`), rather than regular expression notation, will be used to evaluate the patterns. If *parameter* is \* or @, then all the positional parameters, starting with \$1, are substituted (separated by a field separator character). Enclosing the full parameter expansion string in double-quotes will not cause the following four varieties of pattern characters to be quoted, whereas quoting characters within the braces will have this effect.

$\${parameter%word}$  Remove Smallest Suffix Pattern. The *word* will be expanded to produce a pattern. The parameter expansion then will result in *parameter*, with the smallest portion of the suffix matched by the *pattern* deleted.

$\${parameter%%word}$  Remove Largest Suffix Pattern. The *word* will be expanded to produce a pattern. The parameter expansion then will result in *parameter*, with the largest portion of the suffix matched by the *pattern* deleted.

`${parameter#word}` Remove Smallest Prefix Pattern. The *word* will be expanded to produce a pattern. The parameter expansion then will result in *parameter*, with the smallest portion of the prefix matched by the *pattern* deleted.

`${parameter##word}` Remove Largest Prefix Pattern. The *word* will be expanded to produce a pattern. The parameter expansion then will result in *parameter*, with the largest portion of the prefix matched by the *pattern* deleted.

Examples:

`${parameter:-word}`

In this example, `ls` is executed only if `x` is null or unset. (The `$(ls)` command substitution notation is explained in Command Substitution above.)

```
 ${x:-$(ls) }
```

`${parameter:=word}`

```
 unset X
 echo ${X:=abc}
 abc
```

`${parameter:?word}`

```
 unset posix
 echo ${posix:?}
 sh: posix: parameter null or not set
```

`${parameter:+word}`

```
 set a b c
 echo ${3:+posix}
 posix
```

`${#parameter}`

```
 HOME=/usr/posix
 echo ${#HOME}
 10
```

`${parameter%word}`

```
 x=file.c
 echo ${x%.c}.o
 file.o
```

`${parameter%%word}`

```
 x=posix/src/std
 echo ${x%%/*}
 posix
```

ksh(1)

```

${parameter#word}

x=$HOME/src/cmd
echo ${x#$HOME}
/src/cmd

${parameter##word}

x=/one/two/three
echo ${x##*/}
three
```

### Parameters Set by Shell

The following parameters are automatically set by the shell:

|        |                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| #      | The number of positional parameters in decimal.                                                                                                                                                                                                                                                                                                                                              |
| -      | Flags supplied to the shell on invocation or by the <code>set</code> command.                                                                                                                                                                                                                                                                                                                |
| ?      | The decimal value returned by the last executed command.                                                                                                                                                                                                                                                                                                                                     |
| \$     | The process number of this shell.                                                                                                                                                                                                                                                                                                                                                            |
| _      | Initially, the value of <code>_</code> is an absolute pathname of the shell or script being executed as passed in the <i>environment</i> . Subsequently it is assigned the last argument of the previous command. This parameter is not set for commands which are asynchronous. This parameter is also used to hold the name of the matching <code>MAIL</code> file when checking for mail. |
| !      | The process number of the last background command invoked.                                                                                                                                                                                                                                                                                                                                   |
| ERRNO  | The value of <code>errno</code> as set by the most recently failed system call. This value is system dependent and is intended for debugging purposes.                                                                                                                                                                                                                                       |
| LINENO | The line number of the current line within the script or function being executed.                                                                                                                                                                                                                                                                                                            |
| OLDPWD | The previous working directory set by the <code>cd</code> command.                                                                                                                                                                                                                                                                                                                           |
| OPTARG | The value of the last option argument processed by the <code>getopts</code> special command.                                                                                                                                                                                                                                                                                                 |
| OPTIND | The index of the last option argument processed by the <code>getopts</code> special command.                                                                                                                                                                                                                                                                                                 |
| PPID   | The process number of the parent of the shell.                                                                                                                                                                                                                                                                                                                                               |
| PWD    | The present working directory set by the <code>cd</code> command.                                                                                                                                                                                                                                                                                                                            |
| RANDOM | Each time this variable is referenced, a random integer, uniformly distributed between 0 and 32767, is generated. The sequence of random numbers can be initialized by assigning a numeric value to <code>RANDOM</code> .                                                                                                                                                                    |
| REPLY  | This variable is set by the <code>select</code> statement and by the <code>read</code> special command when no arguments are supplied.                                                                                                                                                                                                                                                       |

## Variables Used by Shell

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SECONDS  | Each time this variable is referenced, the number of seconds since shell invocation is returned. If this variable is assigned a value, then the value returned upon reference will be the value that was assigned plus the number of seconds since the assignment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|          | The following variables are used by the shell:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| CDPATH   | The search path for the <code>cd</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| COLUMNS  | If this variable is set, the value is used to define the width of the edit window for the shell edit modes and for printing <code>select</code> lists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| EDITOR   | If the value of this variable ends in <code>emacs</code> , <code>gmacs</code> , or <code>vi</code> and the <code>VISUAL</code> variable is not set, then the corresponding option (see the <code>set</code> special command below) will be turned on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ENV      | <p>This variable, when the shell is invoked, is subjected to parameter expansion by the shell and the resulting value is used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of <code>ENV</code> is not an absolute pathname, the results are unspecified. <code>ENV</code> will be ignored if the user's real and effective user IDs or real and effective group IDs are different.</p> <p>This variable can be used to set aliases and other items local to the invocation of a shell. The file referred to by <code>ENV</code> differs from <code>\$HOME/.profile</code> in that <code>.profile</code> is typically executed at session startup, whereas the <code>ENV</code> file is executed at the beginning of each shell invocation. The <code>ENV</code> value is interpreted in a manner similar to a dot script, in that the commands are executed in the current environment and the file needs to be readable, but not executable. However, unlike dot scripts, no <code>PATH</code> searching is performed. This is used as a guard against Trojan Horse security breaches.</p> |
| FCEDIT   | The default editor name for the <code>fc</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| FPATH    | The search path for function definitions. By default, the <code>FPATH</code> directories are searched after the <code>PATH</code> variable. If an executable file is found, then it is read and executed in the current environment. <code>FPATH</code> is searched before <code>PATH</code> when a function with the <code>-u</code> attribute is referenced. The preset alias <code>autoload</code> causes a function with the <code>-u</code> attribute to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| HISTFILE | If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history. (See <code>Command re-entry</code> below.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## ksh(1)

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HISTSIZE    | If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is 128.                                                                                                                                                                                                                                                                                                                                           |
| HOME        | The default argument (home directory) for the <code>cd</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| IFS         | Internal field separators, normally <code>space</code> , <code>tab</code> , and <code>new-line</code> that are used to separate command words which result from command or parameter substitution and for separating words with the special command <code>read</code> . The first character of the <code>IFS</code> variable is used to separate arguments for the <code>\$*</code> substitution (See <code>Quoting</code> below).                                                                                                              |
| LANG        | Provide a default value for the internationalization variables that are unset or null. If any of the internationalization variables contains an invalid setting, the utility will behave as if none of the variables had been defined.                                                                                                                                                                                                                                                                                                          |
| LC_ALL      | This variable provides a default value for the <code>LC_*</code> variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| LC_COLLATE  | This variable determines the behavior of range expressions, equivalence classes and multi-byte character collating elements within pattern matching.                                                                                                                                                                                                                                                                                                                                                                                            |
| LC_CTYPE    | Determines how the shell handles characters. When <code>LC_CTYPE</code> is set to a valid value, the shell can display and handle text and filenames containing valid characters for that locale. If <code>LC_CTYPE</code> (see <code>environ(5)</code> ) is not set in the environment, the operational behavior of the shell is determined by the value of the <code>LANG</code> environment variable. If <code>LC_ALL</code> is set, its contents are used to override both the <code>LANG</code> and the other <code>LC_*</code> variables. |
| LC_MESSAGES | This variable determines the language in which messages should be written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| LINENO      | This variable is set by the shell to a decimal number representing the current sequential line number (numbered starting with 1) within a script or function before it executes each command. If the user unsets or resets <code>LINENO</code> , the variable may lose its special meaning for the life of the shell. If the shell is not currently executing a script or function, the value of <code>LINENO</code> is unspecified.                                                                                                            |
| LINES       | If this variable is set, the value is used to determine the column length for printing <code>select</code> lists. <code>Select</code> lists will print vertically until about two-thirds of <code>LINES</code> lines are filled.                                                                                                                                                                                                                                                                                                                |
| MAIL        | If this variable is set to the name of a mail file <i>and</i> the <code>MAILPATH</code> variable is not set, then the shell informs the user of arrival of mail in the specified file.                                                                                                                                                                                                                                                                                                                                                          |
| MAILCHECK   | This variable specifies how often (in seconds) the shell will check for changes in the modification time of any of the files specified by                                                                                                                                                                                                                                                                                                                                                                                                       |

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | the MAILPATH or MAIL variables. The default value is 600 seconds. When the time has elapsed the shell will check before issuing the next prompt.                                                                                                                                                                                                                                                                                                    |
| MAILPATH | A colon (:) separated list of file names. If this variable is set, then the shell informs the user of any modifications to the specified files that have occurred within the last MAILCHECK seconds. Each file name can be followed by a ? and a message that will be printed. The message will undergo parameter substitution with the variable \$_ defined as the name of the file that has changed. The default message is you have mail in \$_. |
| NLSPATH  | Determine the location of message catalogues for the processing of LC_MESSAGES.                                                                                                                                                                                                                                                                                                                                                                     |
| PATH     | The search path for commands (see Execution below). The user may not change PATH if executing under rksh (except in .profile).                                                                                                                                                                                                                                                                                                                      |
| PPID     | This variable is set by the shell to the decimal process ID of the process that invoked the shell. In a subshell, PPID will be set to the same value as that of the parent of the current shell. For example, echo \$PPID and (echo \$PPID) would produce the same value.                                                                                                                                                                           |
| PS1      | The value of this variable is expanded for parameter substitution to define the primary prompt string which by default is "\$ ". The character ! in the primary prompt string is replaced by the <i>command</i> number (see Command Re-entry below). Two successive occurrences of ! will produce a single ! when the prompt string is printed.                                                                                                     |
| PS2      | Secondary prompt string, by default "> ".                                                                                                                                                                                                                                                                                                                                                                                                           |
| PS3      | Selection prompt string used within a select loop, by default "#? ".                                                                                                                                                                                                                                                                                                                                                                                |
| PS4      | The value of this variable is expanded for parameter substitution and precedes each line of an execution trace. If omitted, the execution trace prompt is "+ ".                                                                                                                                                                                                                                                                                     |
| SHELL    | The pathname of the <i>shell</i> is kept in the environment. At invocation, if the basename of this variable is rsh, rksh, or krsh, then the shell becomes restricted.                                                                                                                                                                                                                                                                              |
| TMOUT    | If set to a value greater than zero, the shell will terminate if a command is not entered within the prescribed number of seconds after issuing the PS1 prompt. (Notice that the shell can be compiled with a maximum bound for this value which cannot be exceeded.)                                                                                                                                                                               |
| VISUAL   | If the value of this variable ends in emacs, gmacs, or vi, then the corresponding option (see Special Command set below) will be                                                                                                                                                                                                                                                                                                                    |

ksh(1)

turned on.

The shell gives default values to `PATH`, `PS1`, `PS2`, `PS3`, `PS4`, `MAILCHECK`, `FCEDIT`, `TMOUT`, and `IFS`, while `HOME`, `SHELL`, `ENV`, and `MAIL` are not set at all by the shell (although `HOME` is set by `login(1)`). On some systems `MAIL` and `SHELL` are also set by `login`.

**Blank Interpretation**

After parameter and command substitution, the results of substitutions are scanned for the field separator characters (those found in `IFS`) and split into distinct arguments where such characters are found. Explicit null arguments ( `" "` ) or ( `' '` ) are retained. Implicit null arguments (those resulting from *parameters* that have no values) are removed.

**File Name Generation**

Following substitution, each command *word* is scanned for the characters `*`, `?`, and `[` unless the `-f` option has been set. If one of these characters appears, the word is regarded as a *pattern*. The word is replaced with lexicographically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. When a *pattern* is used for file name generation, the character period ( `.` ) at the start of a file name or immediately following a `/`, as well as the character `/` itself, must be matched explicitly. A file name beginning with a period will not be matched with a pattern with the period inside parentheses. That is, `ls .@(r*)` would locate a file named `.restore`, but `ls @(.r*)` would not. In other instances of pattern matching, the `/` and `.` are not treated specially.

- `*` Matches any string, including the null string.
- `?` Matches any single character.
- `[. . .]` Matches any one of the enclosed characters. A pair of characters separated by `-` matches any character lexically between the pair, inclusive. If the first character following the opening `"[ "` is a `!"`, then any character not enclosed is matched. A `-` can be included in the character set by putting it as the first or last character.

A *pattern-list* is a list of one or more patterns separated from each other with a `|`. Composite patterns can be formed with one or more of the following:

- `?(pattern-list)` Optionally matches any one of the given patterns.
- `*(pattern-list)` Matches zero or more occurrences of the given patterns.
- `+(pattern-list)` Matches one or more occurrences of the given patterns.
- `@(pattern-list)` Matches exactly one of the given patterns.
- `!(pattern-list)` Matches anything, except one of the given patterns.

**Quoting**

Each of the *metacharacters* listed above (see `Definitions`) has a special meaning to the shell and causes termination of a word unless quoted. A character may be *quoted* (that is, made to stand for itself) by preceding it with a `\`. The pair `\ NEWLINE` is removed. All characters enclosed between a pair of single quote marks ( `' '` ) are

quoted. A single quote cannot appear within single quotes. Inside double quote marks (" "), parameter and command substitution occur and \ quotes the characters \ , ' , " , and \$. The meaning of \$\* and @\$ is identical when not quoted or when used as a parameter assignment value or as a file name. However, when used as a command argument, \$\* is equivalent to ``\$1\$d \$2d . . . ' ' , where *d* is the first character of the IFS variable, whereas @\$ is equivalent to \$1 \$2 . . . Inside grave quote marks (` `), \ quotes the characters \ , ' , and \$. If the grave quotes occur within double quotes, then \ also quotes the character " .

The special meaning of reserved words or aliases can be removed by quoting any character of the reserved word. The recognition of function names or special command names listed below cannot be altered by quoting them.

### Arithmetic Evaluation

An ability to perform integer arithmetic is provided with the special command `let`. Evaluations are performed using *long* arithmetic. Constants are of the form `[ base# ] n` where *base* is a decimal number between two and thirty-six representing the arithmetic base and *n* is a number in that base. If *base* is omitted then base 10 is used.

An arithmetic expression uses the same syntax, precedence, and associativity of expression as the C language. All the integral operators, other than `++`, `--`, `?:`, and `,` are supported. Variables can be referenced by name within an arithmetic expression without using the parameter substitution syntax. When a variable is referenced, its value is evaluated as an arithmetic expression.

An internal integer representation of a *variable* can be specified with the `-i` option of the `typeset` special command. Arithmetic evaluation is performed on the value of each assignment to a variable with the `-i` attribute. If you do not specify an arithmetic base, the first assignment to the variable determines the arithmetic base. This base is used when parameter substitution occurs.

Since many of the arithmetic operators require quoting, an alternative form of the `let` command is provided. For any command which begins with a `(`, all the characters until a matching `)` are treated as a quoted expression. More precisely, `((. . .))` is equivalent to `let ". . ."`.

### Prompting

When used interactively, the shell prompts with the parameter expanded value of `PS1` before reading a command. If at any time a new-line is typed and further input is needed to complete a command, then the secondary prompt (that is, the value of `PS2`) is issued.

### Conditional Expressions

A *conditional expression* is used with the `[[` compound command to test attributes of files and to compare strings. Word splitting and file name generation are not performed on the words between `[[` and `]]`. Each expression can be constructed from one or more of the following unary or binary expressions:

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <code>-a file</code> | True, if <i>file</i> exists.                                 |
| <code>-b file</code> | True, if <i>file</i> exists and is a block special file.     |
| <code>-c file</code> | True, if <i>file</i> exists and is a character special file. |

ksh(1)

|                                |                                                                                                                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-d file</code>           | True, if <i>file</i> exists and is a directory.                                                                                                                                 |
| <code>-e file</code>           | True, if <i>file</i> exists.                                                                                                                                                    |
| <code>-f file</code>           | True, if <i>file</i> exists and is an ordinary file.                                                                                                                            |
| <code>-g file</code>           | True, if <i>file</i> exists and is has its setgid bit set.                                                                                                                      |
| <code>-k file</code>           | True, if <i>file</i> exists and is has its sticky bit set.                                                                                                                      |
| <code>-n string</code>         | True, if length of <i>string</i> is non-zero.                                                                                                                                   |
| <code>-o option</code>         | True, if option named <i>option</i> is on.                                                                                                                                      |
| <code>-p file</code>           | True, if <i>file</i> exists and is a fifo special file or a pipe.                                                                                                               |
| <code>-r file</code>           | True, if <i>file</i> exists and is readable by current process.                                                                                                                 |
| <code>-s file</code>           | True, if <i>file</i> exists and has size greater than zero.                                                                                                                     |
| <code>-t fildes</code>         | True, if file descriptor number <i>fildes</i> is open and associated with a terminal device.                                                                                    |
| <code>-u file</code>           | True, if <i>file</i> exists and has its setuid bit set.                                                                                                                         |
| <code>-w file</code>           | True, if <i>file</i> exists and is writable by current process.                                                                                                                 |
| <code>-x file</code>           | True, if <i>file</i> exists and is executable by current process. If <i>file</i> exists and is a directory, then the current process has permission to search in the directory. |
| <code>-z string</code>         | True, if length of <i>string</i> is zero.                                                                                                                                       |
| <code>-L file</code>           | True, if <i>file</i> exists and is a symbolic link.                                                                                                                             |
| <code>-O file</code>           | True, if <i>file</i> exists and is owned by the effective user id of this process.                                                                                              |
| <code>-G file</code>           | True, if <i>file</i> exists and its group matches the effective group id of this process.                                                                                       |
| <code>-S file</code>           | True, if <i>file</i> exists and is a socket.                                                                                                                                    |
| <code>file1 -nt file2</code>   | True, if <i>file1</i> exists and is newer than <i>file2</i> .                                                                                                                   |
| <code>file1 -ot file2</code>   | True, if <i>file1</i> exists and is older than <i>file2</i> .                                                                                                                   |
| <code>file1 -ef file2</code>   | True, if <i>file1</i> and <i>file2</i> exist and refer to the same file.                                                                                                        |
| <code>string</code>            | True if the string <i>string</i> is not the null string.                                                                                                                        |
| <code>string = pattern</code>  | True, if <i>string</i> matches <i>pattern</i> .                                                                                                                                 |
| <code>string != pattern</code> | True, if <i>string</i> does not match <i>pattern</i> .                                                                                                                          |
| <code>string1=string2</code>   | True if the strings <i>string1</i> and <i>string2</i> are identical.                                                                                                            |
| <code>string1! =string2</code> | True if the strings <i>string1</i> and <i>string2</i> are not identical.                                                                                                        |

|                                 |                                                                                                                                                |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>string1</i> < <i>string2</i> | True, if <i>string1</i> comes before <i>string2</i> based on strings interpreted as appropriate to the locale setting for category LC_COLLATE. |
| <i>string1</i> > <i>string2</i> | True, if <i>string1</i> comes after <i>string2</i> based on strings interpreted as appropriate to the locale setting for category LC_COLLATE.  |
| <i>exp1</i> -eq <i>exp2</i>     | True, if <i>exp1</i> is equal to <i>exp2</i> .                                                                                                 |
| <i>exp1</i> -ne <i>exp2</i>     | True, if <i>exp1</i> is not equal to <i>exp2</i> .                                                                                             |
| <i>exp1</i> -lt <i>exp2</i>     | True, if <i>exp1</i> is less than <i>exp2</i> .                                                                                                |
| <i>exp1</i> -gt <i>exp2</i>     | True, if <i>exp1</i> is greater than <i>exp2</i> .                                                                                             |
| <i>exp1</i> -le <i>exp2</i>     | True, if <i>exp1</i> is less than or equal to <i>exp2</i> .                                                                                    |
| <i>exp1</i> -ge <i>exp2</i>     | True, if <i>exp1</i> is greater than or equal to <i>exp2</i> .                                                                                 |

In each of the above expressions, if *file* is of the form */dev/fd/n*, where *n* is an integer, then the test is applied to the open file whose descriptor number is *n*.

A compound expression can be constructed from these primitives by using any of the following, listed in decreasing order of precedence.

|                                          |                                                                   |
|------------------------------------------|-------------------------------------------------------------------|
| ( <i>expression</i> )                    | True, if <i>expression</i> is true. Used to group expressions.    |
| ! <i>expression</i>                      | True if <i>expression</i> is false.                               |
| <i>expression1</i> && <i>expression2</i> | True, if <i>expression1</i> and <i>expression2</i> are both true. |
| <i>expression1</i>    <i>expression2</i> | True, if either <i>expression1</i> or <i>expression2</i> is true. |

## Input/Output

Before a command is executed, its input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a simple-command or may precede or follow a *command* and are *not* passed on to the invoked command. Command and parameter substitution occur before *word* or *digit* is used except as noted below. File name generation occurs only if the pattern matches a single file, and blank interpretation is not performed.

|                |                                                                                                                                                                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| < <i>word</i>  | Use file <i>word</i> as standard input (file descriptor 0).                                                                                                                                                                                   |
| > <i>word</i>  | Use file <i>word</i> as standard output (file descriptor 1). If the file does not exist then it is created. If the file exists, and the <code>noclobber</code> option is on, this causes an error; otherwise, it is truncated to zero length. |
| >  <i>word</i> | Sames as >, except that it overrides the <code>noclobber</code> option.                                                                                                                                                                       |

## ksh(1)

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&gt;&gt;word</code>      | Use file <i>word</i> as standard output. If the file exists, output is appended to it (by first seeking to the EOF). Otherwise, the file is created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>&lt;&gt;word</code>      | Open file <i>word</i> for reading and writing as standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>&lt;&lt; [-] word</code> | The shell input is read up to a line that is the same as <i>word</i> , or to an EOF. No parameter substitution, command substitution, or file name generation is performed on <i>word</i> . The resulting document, called a <i>here-document</i> , becomes the standard input. If any character of <i>word</i> is quoted, no interpretation is placed upon the characters of the document. Otherwise, parameter and command substitution occur, <code>\NEWLINE</code> is ignored, and <code>\</code> must be used to quote the characters <code>\</code> , <code>\$</code> , <code>`</code> , and the first character of <i>word</i> . If <code>-</code> is appended to <code>&lt;&lt;</code> , then all leading tabs are stripped from <i>word</i> and from the document. |
| <code>&lt;&amp;digit</code>    | The standard input is duplicated from file descriptor <i>digit</i> (see <code>dup(2)</code> ). Similarly for the standard output using <code>&gt;&amp;digit</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>&lt;&amp;-</code>        | The standard input is closed. Similarly for the standard output using <code>&gt;&amp;-</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>&lt;&amp;p</code>        | The input from the co-process is moved to standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>&gt;&amp;p</code>        | The output to the co-process is moved to standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

If one of the above is preceded by a digit, then the file descriptor number referred to is that specified by the digit (instead of the default 0 or 1). For example:

```
... 2>&1
```

means file descriptor 2 is to be opened for writing as a duplicate of file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates each redirection in terms of the (*file descriptor, file*) association at the time of evaluation. For example:

```
... 1>fname 2>&1
```

first associates file descriptor 1 with file *fname*. It then associates file descriptor 2 with the file associated with file descriptor 1 (that is, *fname*). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and then file descriptor 1 would be associated with file *fname*.

If a command is followed by & and job control is not active, then the default standard input for the command is the empty file `/dev/null`. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

**Environment**

The *environment* (see `environ(5)`) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The names must be *identifiers* and the values are character strings. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a variable for each name found, giving it the corresponding value and marking it *export*. Executed commands inherit the environment. If the user modifies the values of these variables or creates new ones, using the `export` or `typeset -x` commands, they become part of the environment. The environment seen by any executed command is thus composed of any name-value pairs originally inherited by the shell, whose values may be modified by the current shell, plus any additions which must be noted in `export` or `typeset -x` commands.

The environment for any *simple-command* or *function* may be augmented by prefixing it with one or more variable assignments. A variable assignment argument is a word of the form *identifier=value*. Thus:

```
TERM=450 cmd args
```

and

```
(export TERM; TERM=450; cmd args)
```

are equivalent (as far as the above execution of *cmd* is concerned, except for special commands listed below that are preceded with an asterisk).

If the `-k` flag is set, *all* variable assignment arguments are placed in the environment, even if they occur after the command name. The following first prints `a=b c` and then `c`:

```
echo a=b c
set -k echo
a=b c
```

This feature is intended for use with scripts written for early versions of the shell and its use in new scripts is strongly discouraged. It is likely to disappear someday.

**Functions**

The `function` reserved word, described in the `Commands` section above, is used to define shell functions. Shell functions are read in and stored internally. Alias names are resolved when the function is read. Functions are executed like commands with the arguments passed as positional parameters. (See `Execution` below.)

ksh(1)

Functions execute in the same process as the caller and share all files and present working directory with the caller. Traps caught by the caller are reset to their default action inside the function. A trap condition that is not caught or ignored by the function causes the function to terminate and the condition to be passed on to the caller.

A trap on `EXIT` set inside a function is executed after the function completes in the environment of the caller. This is true only for non-POSIX-style functions, that is, functions declared as

```
function func
as opposed to POSIX-style functions, declared as
```

```
func ()
```

Ordinarily, variables are shared between the calling program and the function. However, the `typeset` special command used within a function defines local variables whose scope includes the current function and all functions it calls.

The special command `return` is used to return from function calls. Errors within functions return control to the caller.

The names of all functions can be listed with `typeset+f`. `typeset -f` lists all function names as well as the text of all functions. `typeset -f function-names` lists the text of the named functions only. Functions can be undefined with the `-f` option of the `unset` special command.

Ordinarily, functions are `unset` when the shell executes a shell script. The `-xf` option of the `typeset` command allows a function to be exported to scripts that are executed without a separate invocation of the shell. Functions that need to be defined across separate invocations of the shell should be specified in the `ENV` file with the `-xf` option of `typeset`.

### Function Definition Command

A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a *function definition command*.

The format of a function definition command is as follows:

```
fname () compound-command[io-redirect . . .]
```

The function is named `fname`; it must be a name. An implementation may allow other characters in a function name as an extension. The implementation will maintain separate name spaces for functions and variables.

The `()` in the function definition command consists of two operators. Therefore, intermixing blank characters with the `fname`, `(`, and `)` is allowed, but unnecessary.

The argument *compound-command* represents a compound command.

When the function is declared, none of the expansions in `wordexp` will be performed on the text in *compound-command* or *io-redirect*; all expansions will be performed as normal each time the function is called. Similarly, the optional *io-redirect* redirections and any variable assignments within *compound-command* will be performed during the execution of the function itself, not the function definition.

When a function is executed, it will have the `syntax-error` and `variable-assignment` properties described for the special built-in utilities.

The *compound-command* will be executed whenever the function name is specified as the name of a simple command. The operands to the command temporarily will become the positional parameters during the execution of the *compound-command*; the special parameter `#` will also be changed to reflect the number of operands. The special parameter `0` will be unchanged. When the function completes, the values of the positional parameters and the special parameter `#` will be restored to the values they had before the function was executed. If the special built-in `return` is executed in the *compound-command*, the function will complete and execution will resume with the next command after the function call.

An example of how a function definition can be used wherever a simple command is allowed:

```
If variable i is equal to "yes",
define function foo to be ls -l
#
["$i" = yes] && foo() {
 ls -l
}
```

The exit status of a function definition will be `0` if the function was declared successfully; otherwise, it will be greater than zero. The exit status of a function invocation will be the exit status of the last command executed by the function.

**Jobs** If the `monitor` option of the `set` command is turned on, an interactive shell associates a `job` with each pipeline. It keeps a table of current jobs, printed by the `jobs` command, and assigns them small integer numbers. When a job is started asynchronously with `&`, the shell prints a line which looks like:

```
[1] 1234
```

indicating that the `job`, which was started asynchronously, was job number `1` and had one (top-level) process, whose process id was `1234`.

If you are running a job and wish to do something else you may press the key `^Z` (Control-Z) which sends a `STOP` signal to the current job. The shell will then normally indicate that the job has been '`stopped`', and print another prompt. You can then manipulate the state of this job, putting it in the background with the `bg` command, or run some other commands and then eventually bring the job back into the foreground with the foreground command `fg`. A `^Z` takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.

ksh(1)

A job being run in the background will stop if it tries to read from the terminal. Background jobs are normally allowed to produce output, but this can be disabled by giving the command "stty tostop". If you set this tty option, then background jobs will stop when they try to produce output as they do when they try to read input.

There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

|                        |                                                        |
|------------------------|--------------------------------------------------------|
| <code>%number</code>   | The job with the given number.                         |
| <code>%string</code>   | Any job whose command line begins with <i>string</i> . |
| <code>;%?string</code> | Any job whose command line contains <i>string</i> .    |
| <code>%%</code>        | Current job.                                           |
| <code>%+</code>        | Equivalent to <code>%%</code> .                        |
| <code>%-</code>        | Previous job.                                          |

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work.

When the monitor mode is on, each background job that completes triggers any trap set for CHLD.

When you try to leave the shell while jobs are running or stopped, you will be warned with the message, 'You have stopped (running) jobs.' You may use the `jobs` command to see what they are. If you do this or immediately try to exit again, the shell will not warn you a second time, and the stopped jobs will be terminated. If you have `nohup`'ed jobs running when you attempt to logout, you will be warned with the message:

```
You have jobs running.
```

You will then need to logout a second time to actually logout. However, your background jobs will continue to run.

**Signals** The `INT` and `QUIT` signals for an invoked command are ignored if the command is followed by `&` and the `monitor` option is not active. Otherwise, signals have the values inherited by the shell from its parent (but see also the `trap` special command below).

**Execution** Each time a command is executed, the above substitutions are carried out. If the command name matches one of the `Special Commands` listed below, it is executed within the current shell process. Next, the command name is checked to see if it matches one of the user defined functions. If it does, the positional parameters are saved and then reset to the arguments of the `function` call. When the `function` completes or issues a `return`, the positional parameter list is restored and any trap set on `EXIT` within the function is executed. The value of a `function` is the value of the

last command executed. A function is also executed in the current shell process. If a command name is not a `special` command or a user defined `function`, a process is created and an attempt is made to execute the command via `exec(2)`.

The shell variable `PATH` defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is `/bin:/usr/bin:` (specifying `/bin`, `/usr/bin`, and the current directory in that order). The current directory can be specified by two or more adjacent colons, or by a colon at the beginning or end of the path list. If the command name contains a `/` then the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not a directory or an `a.out` file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. All non-exported aliases, functions, and variables are removed in this case. A parenthesized command is executed in a sub-shell without removing non-exported quantities.

### Command Re-entry

The text of the last `HISTSIZE` (default 128) commands entered from a terminal device is saved in a `history` file. The file `$HOME/.sh_history` is used if the `HISTFILE` variable is not set or if the file it names is not writable. A shell can access the commands of all *interactive* shells which use the same named `HISTFILE`. The special command `fc` is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to `fc` then the value of the variable `FCEDIT` is used. If `FCEDIT` is not defined, then `/bin/ed` is used. The edited command(s) is printed and re-executed upon leaving the editor. The editor name `-` is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form `old=new` can be used to modify the command before execution. For example, if `r` is aliased to `'fc -e -'` then typing `'r bad=good c'` will re-execute the most recent command which starts with the letter `c`, replacing the first occurrence of the string `bad` with the string `good`.

### In-line Editing Option

Normally, each command line entered from a terminal device is simply typed followed by a new-line (RETURN or LINEFEED). If either the `emacs`, `gmacs`, or `vi` option is active, the user can edit the command line. To be in either of these edit modes set the corresponding option. An editing option is automatically selected each time the `VISUAL` or `EDITOR` variable is assigned a value ending in either of these option names.

The editing features require that the user's terminal accept RETURN as carriage return without line feed and that a space must overwrite the current character on the screen.

The editing modes implement a concept where the user is looking through a window at the current line. The window width is the value of `COLUMNS` if it is defined, otherwise 80. If the window width is too small to display the prompt and leave at least 8 columns to enter input, the prompt is truncated from the left. If the line is longer than the window width minus two, a mark is displayed at the end of the window to

ksh(1)

notify the user. As the cursor moves and reaches the window boundaries the window will be centered about the cursor. The mark is a > if the line extends on the right side of the window, < if the line extends on the left, and \* if the line extends on both sides of the window.

The search commands in each edit mode provide access to the history file. Only strings are matched, not patterns, although a leading caret (^) in the string restricts the match to begin at the first character in the line.

### emacs Editing Mode

This mode is entered by enabling either the `emacs` or `gmacs` option. The only difference between these two modes is the way they handle ^T. To edit, move the cursor to the point needing correction and then insert or delete characters or words as needed. All the editing commands are control characters or escape sequences. The notation for control characters is caret (^) followed by the character. For example, ^F is the notation for control F. This is entered by depressing 'f' while holding down the CTRL (control) key. The SHIFT key is *not* depressed. (The notation ^? indicates the DEL (delete) key.)

The notation for escape sequences is M- followed by a character. For example, M-f (pronounced Meta f) is entered by depressing ESC (ascii 033) followed by 'f'. (M-F would be the notation for ESC followed by SHIFT (capital) 'F'.)

All edit commands operate from any place on the line (not just at the beginning). Neither the RETURN nor the LINEFEED key is entered after edit commands except when noted.

|                  |                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| ^F               | Move cursor forward (right) one character.                                                                                                      |
| M-f              | Move cursor forward one word. (The emacs editor's idea of a word is a string of characters consisting of only letters, digits and underscores.) |
| ^B               | Move cursor backward (left) one character.                                                                                                      |
| M-b              | Move cursor backward one word.                                                                                                                  |
| ^A               | Move cursor to start of line.                                                                                                                   |
| ^E               | Move cursor to end of line.                                                                                                                     |
| ^] <i>char</i>   | Move cursor forward to character <i>char</i> on current line.                                                                                   |
| M-^] <i>char</i> | Move cursor backward to character <i>char</i> on current line.                                                                                  |
| ^X^X             | Interchange the cursor and mark.                                                                                                                |
| <i>erase</i>     | (User defined erase character as defined by the <code>stty(1)</code> command, usually ^H or #.) Delete previous character.                      |
| ^D               | Delete current character.                                                                                                                       |
| M-d              | Delete current word.                                                                                                                            |
| M-^H             | (Meta-backspace) Delete previous word.                                                                                                          |

|             |                                                                                                                                                                                                                                                                                                                                                |

| M-h         | Delete previous word.                                                                                                                                                                                                                                                                                                                          |
| M-^?        | (Meta-DEL) Delete previous word (if your interrupt character is ^? (DEL, the default) then this command will not work).                                                                                                                                                                                                                        |
| ^T          | Transpose current character with next character in <code>emacs</code> mode.<br>Transpose two previous characters in <code>gmacs</code> mode.                                                                                                                                                                                                   |
| ^C          | Capitalize current character.                                                                                                                                                                                                                                                                                                                  |
| M-c         | Capitalize current word.                                                                                                                                                                                                                                                                                                                       |
| M-l         | Change the current word to lower case.                                                                                                                                                                                                                                                                                                         |
| ^K          | Delete from the cursor to the end of the line. If preceded by a numerical parameter whose value is less than the current cursor position, then delete from given position up to the cursor. If preceded by a numerical parameter whose value is greater than the current cursor position, then delete from cursor up to given cursor position. |
| ^W          | Kill from the cursor to the mark.                                                                                                                                                                                                                                                                                                              |
| M-p         | Push the region from the cursor to the mark on the stack.                                                                                                                                                                                                                                                                                      |
| <i>kill</i> | (User defined kill character as defined by the <code>stty(1)</code> command, usually ^G or @.) Kill the entire current line. If two <i>kill</i> characters are entered in succession, all kill characters from then on cause a line feed (useful when using paper terminals).                                                                  |
| ^Y          | Restore last item removed from line. (Yank item back to the line.)                                                                                                                                                                                                                                                                             |
| ^L          | Line feed and print current line.                                                                                                                                                                                                                                                                                                              |
| ^@          | (null character) Set mark.                                                                                                                                                                                                                                                                                                                     |
| M-space     | (Meta space) Set mark.                                                                                                                                                                                                                                                                                                                         |
| J           | (New line) Execute the current line.                                                                                                                                                                                                                                                                                                           |
| M           | (Return) Execute the current line.                                                                                                                                                                                                                                                                                                             |
| <i>eof</i>  | End-of-file character, normally ^D, is processed as an End-of-file only if the current line is null.                                                                                                                                                                                                                                           |
| ^P          | Fetch previous command. Each time ^P is entered the previous command back in time is accessed. Moves back one line when not on the first line of a multi-line command.                                                                                                                                                                         |
| M-<         | Fetch the least recent (oldest) history line.                                                                                                                                                                                                                                                                                                  |
| M->         | Fetch the most recent (youngest) history line.                                                                                                                                                                                                                                                                                                 |
| ^N          | Fetch next command line. Each time ^N is entered the next command line forward in time is accessed.                                                                                                                                                                                                                                            |

ksh(1)

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>^Rstring</code>         | Reverse search history for a previous command line containing <i>string</i> . If a parameter of zero is given, the search is forward. <i>string</i> is terminated by a RETURN or NEW LINE. If <i>string</i> is preceded by a <code>^</code> , the matched line must begin with <i>string</i> . If <i>string</i> is omitted, then the next command line containing the most recent <i>string</i> is accessed. In this case a parameter of zero reverses the direction of the search.                                                  |
| <code>^O</code>               | Operate. Execute the current line and fetch the next line relative to current line from the history file.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>M-digits</code>         | (Escape) Define numeric parameter, the digits are taken as a parameter to the next command. The commands that accept a parameter are <code>^F</code> , <code>^B</code> , <i>erase</i> , <code>^C</code> , <code>^D</code> , <code>^K</code> , <code>^R</code> , <code>^P</code> , <code>^N</code> , <code>^]</code> , <code>M-.</code> , <code>M-^]</code> , <code>M-_<code></code></code> , <code>M-b</code> , <code>M-c</code> , <code>M-d</code> , <code>M-f</code> , <code>M-h</code> , <code>M-l</code> and <code>M-^H</code> . |
| <code>M-letter</code>         | Soft-key. Your alias list is searched for an alias by the name <code>_letter</code> and if an alias of this name is defined, its value will be inserted on the input queue. The <i>letter</i> must not be one of the above meta-functions.                                                                                                                                                                                                                                                                                           |
| <code>M- [letter</code>       | Soft-key. Your alias list is searched for an alias by the name <code>__letter</code> and if an alias of this name is defined, its value will be inserted on the input queue. The can be used to program functions keys on many terminals.                                                                                                                                                                                                                                                                                            |
| <code>M-.</code>              | The last word of the previous command is inserted on the line. If preceded by a numeric parameter, the value of this parameter determines which word to insert rather than the last word.                                                                                                                                                                                                                                                                                                                                            |
| <code>M-_<code></code></code> | Same as <code>M-.</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>M-*</code>              | An asterisk is appended to the end of the word and a file name expansion is attempted.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>M-ESC</code>            | File name completion. Replaces the current word with the longest common prefix of all filenames matching the current word with an asterisk appended. If the match is unique, a <code>/</code> is appended if the file is a directory and a space is appended if the file is not a directory.                                                                                                                                                                                                                                         |
| <code>M-=</code>              | List files matching current word pattern if an asterisk were appended.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>^U</code>               | Multiply parameter of next command by 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>\</code>                | Escape next character. Editing characters, the user's <i>erase</i> , <i>kill</i> and <i>interrupt</i> (normally <code>^?</code> ) characters may be entered in a command line or in a search string if preceded by a <code>\</code> . The <code>\</code> removes the next character's editing features (if any).                                                                                                                                                                                                                     |
| <code>^V</code>               | Display version of the shell.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                             |                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                             | M-#               | Insert a # at the beginning of the line and execute it. This causes a comment to be inserted in the history file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>vi Editing Mode</b>      |                   | <p>There are two typing modes. Initially, when you enter a command you are in the <i>input</i> mode. To edit, enter <i>control</i> mode by typing ESC (033) and move the cursor to the point needing correction and then insert or delete characters or words as needed. Most control commands accept an optional repeat <i>count</i> prior to the command.</p> <p>When in <i>vi</i> mode on most systems, canonical processing is initially enabled and the command will be echoed again if the speed is 1200 baud or greater and it contains any control characters or less than one second has elapsed since the prompt was printed. The ESC character terminates canonical processing for the remainder of the command and the user can then modify the command line. This scheme has the advantages of canonical processing with the type-ahead echoing of raw mode.</p> <p>If the option <i>viraw</i> is also set, the terminal will always have canonical processing disabled. This mode is implicit for systems that do not support two alternate end of line delimiters, and may be helpful for certain terminals.</p> |
| <b>Input Edit Commands</b>  |                   | By default the editor is in input mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                             | <i>erase</i>      | (User defined erase character as defined by the <i>stty(1)</i> command, usually ^H or #.) Delete previous character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                             | ^W                | Delete the previous blank separated word.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                             | ^D                | Terminate the shell.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                             | ^V                | Escape next character. Editing characters and the user's erase or kill characters may be entered in a command line or in a search string if preceded by a ^v. The ^v removes the next character's editing features (if any).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                             | \                 | Escape the next <i>erase</i> or <i>kill</i> character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Motion Edit Commands</b> |                   | These commands will move the cursor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                            | U                                                                                                                                                                                                                                                                                                                                                              | Undo all the text modifying commands performed on the line.                                                                                                                                                                                                                    |
|                            | [ <i>count</i> ]v                                                                                                                                                                                                                                                                                                                                              | Returns the command <code>fc -e \${VISUAL:-\${EDITOR:-vi}}</code> <i>count</i> in the input buffer. If <i>count</i> is omitted, then the current line is used.                                                                                                                 |
|                            | ^L                                                                                                                                                                                                                                                                                                                                                             | Line feed and print current line. Has effect only in control mode.                                                                                                                                                                                                             |
|                            | J                                                                                                                                                                                                                                                                                                                                                              | (New line) Execute the current line, regardless of mode.                                                                                                                                                                                                                       |
|                            | M                                                                                                                                                                                                                                                                                                                                                              | (Return) Execute the current line, regardless of mode.                                                                                                                                                                                                                         |
| #                          | If the first character of the command is a #, then this command deletes this # and each # that follows a newline. Otherwise, sends the line after inserting a # in front of each line in the command. Useful for causing the current line to be inserted in the history as a comment and removing comments from previous comment commands in the history file. |                                                                                                                                                                                                                                                                                |
| =                          | List the file names that match the current word if an asterisk were appended it.                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                |
| @ <i>letter</i>            | Your alias list is searched for an alias by the name <i>letter</i> and if an alias of this name is defined, its value will be inserted on the input queue for processing.                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                |
| <b>Special Commands</b>    | The following <i>simple-commands</i> are executed in the shell process. Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is 0. Commands that are preceded by one or two * (asterisks) are treated specially in the following ways:            |                                                                                                                                                                                                                                                                                |

1. Variable assignment lists preceding the command remain in effect when the command completes.
  2. I/O redirections are processed after variable assignments.
  3. Errors cause a script that contains them to abort.
  4. Words, following a command preceded by **\*\*** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.
- \*** : [ *arg* . . . ]  
The command only expands parameters.
- \*** . *file* [ *arg* . . . ]  
Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by `PATH` is used to find the directory containing *file*. If any arguments *arg* are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed.
- \*\*** alias [ -*tx* ] [ *name*[ =*value* ] ] . . .  
alias with no arguments prints the list of aliases in the form *name=value* on standard output. An *alias* is defined for each name whose *value* is given. A trailing space in *value* causes the next word to be checked for alias substitution. The -*t* flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given *name*. The value becomes undefined when the value of `PATH` is reset but the aliases remained tracked. Without the -*t* flag, for each *name* in the argument list for which no *value* is given, the name and value of the alias is printed. The -*x* flag is used to set or print *exported aliases*. An *exported alias* is defined for scripts invoked by name. The exit status is non-zero if a *name* is given, but no value, and no alias has been defined for the *name*.
- bg** [ %*job*. . . ]  
This command is only on systems that support job control. Puts each specified *job* into the background. The current job is put in the background if *job* is not specified. See "Jobs" section above for a description of the format of *job*.
- \*** break [ *n* ]  
Exit from the enclosed *for*, *while*, *until*, or *select* loop, if any. If *n* is specified then break *n* levels.
- \*** continue [ *n* ]  
Resume the next iteration of the enclosed *for*, *while*, *until*, or *select* loop. If *n* is specified then resume at the *n*-th enclosed loop.
- cd** [ *arg* ]  
**cd** *old new*  
This command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is - the directory is changed to the previous directory. The shell variable `HOME` is the default *arg*. The variable `PWD` is set to the current directory. The shell variable `CDPATH` defines the search path for the directory

## ksh(1)

containing *arg*. Alternative directory names are separated by a colon (:). The default path is null (specifying the current directory). Notice that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a / then the search path is not used. Otherwise, each directory in the path is searched for *arg*.

The second form of `cd` substitutes the string *new* for the string *old* in the current directory name, `PWD` and tries to change to this new directory. The `cd` command may not be executed by `rksh`.

`command [-p] [command_name] [argument . . .]`

`command [-v -V] command_name`

The `command` utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup. The `-p` flag performs the command search using a default value for `PATH` that is guaranteed to find all of the standard utilities. The `-v` flag writes a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment, to invoke *command\_name*. The `-V` flag writes a string to standard output that indicates how the name given in the *command\_name* operand will be interpreted by the shell, in the current shell execution environment.

`echo [ arg . . . ]`

See `echo(1)` for usage and description.

\* `eval [ arg . . . ]`

The arguments are read as input to the shell and the resulting command(s) executed.

\* `exec [ arg . . . ]`

If *arg* is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.

\* `exit [ n ]`

Causes the calling shell or shell script to exit with the exit status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the exit status is that of the last command executed. When `exit` occurs when executing a trap, the last command refers to the command that executed before the trap was invoked. An EOF will also cause the shell to exit except for a shell which has the `ignoreeof` option (See `set` below) turned on.

\*\* `export [ name[=value] ] . . .`

The given *names* are marked for automatic export to the environment of subsequently-executed commands.

`fc [-e ename ] [-nlr] [first [last ]]`

`fc -e - [ old=new ] [ command ]`

In the first form, a range of commands from *first* to *last* is selected from the last HISTSIZE commands that were typed at the terminal. The arguments *first* and *last* may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the `-1` flag is selected, the commands are listed on standard output. Otherwise, the editor program *ename* is invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the variable FCEDIT (default `/bin/ed`) is used as the editor. When editing is complete, the edited command(s) is executed. If *last* is not specified then it will be set to *first*. If *first* is not specified the default is the previous command for editing and `-16` for listing. The flag `-r` reverses the order of the commands and the flag `-n` suppresses command numbers when listing. In the second form the command is re-executed after the substitution *old=new* is performed. If there is not a *command* argument, the most recent command typed at this terminal is executed.

fg [ %*job*. . . ]

This command is only on systems that support job control. Each *job* specified is brought to the foreground. Otherwise, the current job is brought into the foreground. See "Jobs" section above for a description of the format of *job*.

getopts *optstring name* [ *arg* . . . ]

Checks *arg* for legal options. If *arg* is omitted, the positional parameters are used. An option argument begins with a `+` or a `-`. An option not beginning with `+` or `-` or the argument `-` ends the options. *optstring* contains the letters that `getopts` recognizes. If a letter is followed by a `:`, that option is expected to have an argument. The options can be separated from the argument by blanks.

`getopts` places the next option letter it finds inside variable *name* each time it is invoked with a `+` prepended when *arg* begins with a `+`. The index of the next *arg* is stored in OPTIND. The option argument, if any, gets stored in OPTARG.

A leading `:` in *optstring* causes `getopts` to store the letter of an invalid option in OPTARG, and to set *name* to `?` for an unknown option and to `:` when a required option is missing. Otherwise, `getopts` prints an error message. The exit status is non-zero when there are no more options. See `getoptcvt(1)` for usage and description.

hash [ *name* . . . ]

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The `-r` option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (\*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

## ksh(1)

`jobs [ -lnp ] [ %job ... ]`

Lists information about each given job; or all active jobs if *job* is omitted. The `-l` flag lists process ids in addition to the normal information. The `-n` flag displays only jobs that have stopped or exited since last notified. The `-p` flag causes only the process group to be listed. See "Jobs" section above and `jobs(1)` for a description of the format of *job*.

`kill [ -sig ] %job ...`

`kill [ -sig ] pid ...`

`kill -l`

Sends either the `TERM` (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in `signal(3HEAD)` stripped of the prefix "SIG" with the exception that `SIGCHD` is named `CHLD`). If the signal being sent is `TERM` (terminate) or `HUP` (hangup), then the job or process will be sent a `CONT` (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See `Jobs` for a description of the format of *job*. In the second form, `kill -l`, the signal numbers and names are listed.

`let arg ...`

Each *arg* is a separate *arithmetic expression* to be evaluated. See the `Arithmetic Evaluation` section above, for a description of arithmetic expression evaluation.

The exit status is 0 if the value of the last expression is non-zero, and 1 otherwise.

`login argument ...`

Equivalent to `'exec login argument. ...'` See `login(1)` for usage and description.

`* newgrp [ arg ... ]`

Equivalent to `exec /bin/newgrp arg ...`

`print [ -Rnrpsu[n] ] [ arg ... ]`

The shell output mechanism. With no flags or with flag `-` or `-`, the arguments are printed on standard output as described by `echo(1)`. The exit status is 0, unless the output file is not open for writing.

`-n` Suppress `NEWLINE` from being added to the output.

`-R | -r` Raw mode. Ignore the escape conventions of `echo`. The `-R` option will print all subsequent arguments and options other than `-n`.

`-p` Write the arguments to the pipe of the process spawned with `| &` instead of standard output.

`-s` Write the arguments to the history file instead of standard output.

`-u [ n ]` Specify a one digit file descriptor unit number *n* on which the output will be placed. The default is 1.

`pwd`

Equivalent to `print -r - $PWD`.

```
read [-prsu[n]] [name?prompt] [name . . .]
```

The shell input mechanism. One line is read and is broken up into fields using the characters in IFS as separators. The escape character, (`\`), is used to remove any special meaning for the next character and for line continuation. In raw mode, `-r`, the `\` character is not treated specially. The first field is assigned to the first *name*, the second field to the second *name*, etc., with leftover fields assigned to the last *name*. The `-p` option causes the input line to be taken from the input pipe of a process spawned by the shell using `|&`. If the `-s` flag is present, the input will be saved as a command in the history file. The flag `-u` can be used to specify a one digit file descriptor unit *n* to read from. The file descriptor can be opened with the `exec` special command. The default value of *n* is 0. If *name* is omitted then `REPLY` is used as the default *name*. The exit status is 0 unless the input file is not open for reading or an EOF is encountered. An EOF with the `-p` option causes cleanup for this process so that another can be spawned. If the first argument contains a `?`, the remainder of this word is used as a *prompt* on standard error when the shell is interactive. The exit status is 0 unless an EOF is encountered.

```
** readonly [name[=value]] . . .
```

The given *names* are marked `readonly` and these names cannot be changed by subsequent assignment.

```
* return [n]
```

Causes a shell function or `'.'` script to return to the invoking script with the return status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the return status is that of the last command executed. If return is invoked while not in a function or a `'.'` script, then it is the same as an `exit`.

```
set [±abCefhkmnopstuvx] [±o option] . . . [±A name] [arg . . .]
```

The flags for this command have meaning as follows:

- A        Array assignment. Unset the variable *name* and assign values sequentially from the list *arg*. If `+A` is used, the variable *name* is not unset first.
- a        All subsequent variables that are defined are automatically exported.
- b        Causes the shell to notify the user asynchronously of background job completions. The following message will be written to standard error:

```
" [%d] %c %s%s\n" , <job-number>, <current>, <status>, <job-name>
```

where the fields are as follows:

`<current>`        The character `+` identifies the job that would be used as a default for the `fg` or `bg` utilities; this job can also be specified using the `job_id %+` or `%%`. The character `-` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the `job_id %-`. For other jobs, this

ksh(1)

field is a space character. At most one job can be identified with + and at most one job can be identified with -. If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job.

*<job-number>* A number that can be used to identify the process group to the `wait`, `fg`, `bg`, and `kill` utilities. Using these utilities, the job can be identified by prefixing the job number with %.

*<status>* Unspecified.

*<job-name>* Unspecified.

When the shell notifies the user a job has been completed, it may remove the job's process ID from the list of those known in the current shell execution environment. Asynchronous notification will not be enabled by default.

- C Prevent existing files from being overwritten by the shell's > redirection operator. The >| redirection operator will override this `noclobber` option for an individual file.
- e If a command has a non-zero exit status, execute the ERR trap, if set, and exit. This mode is disabled while reading profiles.
- f Disables file name generation.
- h Each command becomes a tracked alias when first encountered.
- k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- n Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.
- o The following argument can be one of the following option names:
  - `allexport` Same as -a.
  - `errexit` Same as -e.
  - `bgnice` All background jobs are run at a lower priority. This is the default mode.
  - `emacs` Puts you in an emacs style in-line editor for command entry.

|                         |                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gmacs</code>      | Puts you in a <code>gmacs</code> style in-line editor for command entry.                                                                                                    |
| <code>ignoreeof</code>  | The shell will not exit on EOF. The command <code>exit</code> must be used.                                                                                                 |
| <code>keyword</code>    | Same as <code>-k</code> .                                                                                                                                                   |
| <code>markdirs</code>   | All directory names resulting from file name generation have a trailing <code>/</code> appended.                                                                            |
| <code>monitor</code>    | Same as <code>-m</code> .                                                                                                                                                   |
| <code>noclobber</code>  | Prevents redirection <code>&gt;</code> from truncating existing files. Require <code>&gt; </code> to truncate a file when turned on. Equivalent to <code>-C</code> .        |
| <code>noexec</code>     | Same as <code>-n</code> .                                                                                                                                                   |
| <code>noglob</code>     | Same as <code>-f</code> .                                                                                                                                                   |
| <code>nolog</code>      | Do not save function definitions in history file.                                                                                                                           |
| <code>notify</code>     | Equivalent to <code>-b</code> .                                                                                                                                             |
| <code>nounset</code>    | Same as <code>-u</code> .                                                                                                                                                   |
| <code>privileged</code> | Same as <code>-p</code> .                                                                                                                                                   |
| <code>verbose</code>    | Same as <code>-v</code> .                                                                                                                                                   |
| <code>trackall</code>   | Same as <code>-h</code> .                                                                                                                                                   |
| <code>vi</code>         | Puts you in insert mode of a <code>vi</code> style in-line editor until you hit escape character <code>033</code> . This puts you in control mode. A return sends the line. |
| <code>viraw</code>      | Each character is processed as it is typed in <code>vi</code> mode.                                                                                                         |
| <code>xtrace</code>     | Same as <code>-x</code> .                                                                                                                                                   |

If no option name is supplied, the current option settings are printed.

- `-p` Disables processing of the `$HOME/.profile` file and uses the file `/etc/suid_profile` instead of the `ENV` file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.
- `-s` Sort the positional parameters lexicographically.
- `-t` Exit after reading and executing one command.
- `-u` Treat unset parameters as an error when substituting.
- `-v` Print shell input lines as they are read.

## ksh(1)

`-x` Print commands and their arguments as they are executed.

`-` Turns off `-x` and `-v` flags and stops examining arguments for flags.

`—` Do not change any of the flags; useful in setting `$1` to a value beginning with `-`. If no arguments follow this flag then the positional parameters are unset.

Using `+` rather than `-` causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in `$-`. Unless `-A` is specified, the remaining arguments are positional parameters and are assigned, in order, to `$1 $2 . . .`. If no arguments are given, the names and values of all variables are printed on the standard output.

`* shift [ n ]`  
The positional parameters from `$n+1 $n+1 . . .` are renamed `$1 . . .`, default `n` is 1. The parameter `n` can be any arithmetic expression that evaluates to a non-negative number less than or equal to `$#`.

`stop%jobid . . .`

`stop pid . . .`  
`stop` stops the execution of a background job(s) by using its *jobid*, or of any process by using its *pid*. (see `ps(1)`).

`suspend`  
Stops the execution of the current shell (but not if it is the login shell).

`test expression`  
Evaluate conditional expressions. See Conditional Expressions section above and `test(1)` for usage and description.

`* times`  
Print the accumulated user and system times for the shell and for processes run from the shell.

`* trap [ arg sig . . . ]`  
*arg* is a command to be read and executed when the shell receives signal(s) *sig*. *arg* is scanned once when the trap is set and once when the trap is taken. *sig* can be specified as a signal number or signal name. `trap` commands are executed in order of signal number. Any attempt to set a trap on a signal number that was ignored on entry to the current shell is ineffective.

If *arg* is `-`, the shell will reset each *sig* to the default value. If *arg* is null (`' '`), the shell will ignore each specified *sig* if it arises. Otherwise, *arg* will be read and executed by the shell when one of the corresponding *sigs* arises. The action of the trap will override a previous action (either default action or one explicitly set). The value of `$?` after the trap action completes will be the value it had before the trap was invoked.

*sig* can be EXIT, 0 (equivalent to EXIT) or a signal specified using a symbolic name, without the SIG prefix, for example, HUP, INT, QUIT, TERM. If *sig* is 0 or EXIT and the trap statement is executed inside the body of a function, then the command *arg* is executed after the function completes. If *sig* is 0 or EXIT for a trap set outside any function, the command *arg* is executed on exit from the shell. If *sig* is ERR, *arg* will be executed whenever a command has a non-zero exit status. If *sig* is DEBUG, *arg* will be executed after each command.

The environment in which the shell executes a trap on EXIT will be identical to the environment immediately after the last command executed before the trap on EXIT was taken.

Each time the trap is invoked, *arg* will be processed in a manner equivalent to eval "\$arg".

Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell may reset or catch signals ignored on entry. Traps will remain in place for a given shell until explicitly changed with another trap command.

When a subshell is entered, traps are set to the default args. This does not imply that the trap command cannot be used within the subshell to set new traps.

The trap command with no arguments will write to standard output a list of commands associated with each sig. The format is:

```
trap -- %s %s . . . <arg>, <sig> . . .
```

The shell will format the output, including the proper use of quoting, so that it is suitable for reininput to the shell as commands that achieve the same trapping results. For example:

```
save_traps=$(trap)
. . .
eval "$save_traps"
```

If the trap name or number is invalid, a non-zero exit status will be returned; otherwise, 0 will be returned. For both interactive and non-interactive shells, invalid signal names or numbers will not be considered a syntax error and will not cause the shell to abort.

Traps are not processed while a job is waiting for a foreground process. Thus, a trap on CHLD won't be executed until the foreground job terminates.

type *name* . . .

For each *name*, indicate how it would be interpreted if used as a command name.

\*\* typeset [ ±HLRZfilrtux[*n*] ] [ *name*[=*value*] ] . . .

Sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables *name* is created. The variables *value* and *type* are restored when the function completes. The following list of attributes may be specified:

## ksh(1)

- H This flag provides UNIX to host-name file mapping on non-UNIX machines.
- L Left justify and remove leading blanks from *value*. If *n* is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the -Z flag is also set. The -R flag is turned off.
- R Right justify and fill with leading blanks. If *n* is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The -L flag is turned off.
- Z Right justify and fill with leading zeros if the first non-blank character is a digit and the -L flag has not been set. If *n* is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment.
- f The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are -t, -u, and -x. The flag -t turns on execution tracing for this function. The flag -u causes this function to be marked undefined. The FPATH variable will be searched to find the function definition when the function is referenced. The flag -x allows the function definition to remain in effect across shell procedures invoked by name.
- i Parameter is an integer. This makes arithmetic faster. If *n* is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.
- l All upper-case characters are converted to lower-case. The upper-case flag, -u is turned off.
- r The given *names* are marked `readonly` and these names cannot be changed by subsequent assignment.
- t Tags the variables. Tags are user definable and have no special meaning to the shell.
- u All lower-case characters are converted to upper-case characters. The lower-case flag, -l is turned off.
- x The given *names* are marked for automatic export to the environment of subsequently-executed commands.

The -i attribute can not be specified along with -R, -L, -Z, or -f.

Using + rather than – causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using + rather than – keeps the values from being printed.) If no *names* and flags are given, the *names* and *attributes* of all *variables* are printed.

`ulimit [ -HSacdfnstv ] [ limit ]`

Set or display a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value `unlimited`. The `H` and `S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the `H` or `S` options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case the soft limit is printed unless `H` is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- `-a` Lists all of the current resource limits.
- `-c` The number of 512-byte blocks on the size of core dumps.
- `-d` The number of K-bytes on the size of the data area.
- `-f` The number of 512-byte blocks on files written by child processes (files of any size may be read).
- `-n` The number of file descriptors plus 1.
- `-s` The number of K-bytes on the size of the stack area.
- `-t` The number of seconds to be used by each process.
- `-v` The number of K-bytes for virtual memory.

If no option is given, `-f` is assumed.

`umask [-S] [ mask ]`

The user file-creation mask is set to *mask* (see `umask(2)`). *mask* can either be an octal number or a symbolic value as described in `chmod(1)`. If a symbolic value is given, the new `umask` value is the complement of the result of applying *mask* to the complement of the previous `umask` value. If *mask* is omitted, the current value of the mask is printed. The `-S` flag produces symbolic output.

`unalias name . . .`

The *aliases* given by the list of *names* are removed from the *alias* list.

`unset [ -f ] name . . .`

The variables given by the list of *names* are unassigned, that is, their values and attributes are erased. `readonly` variables cannot be unset. If the `-f`, flag is set, then the names refer to *function* names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOUT`, and `_` removes their special meaning even if they are subsequently assigned to.

## ksh(1)

\* `wait [ job ]`

Wait for the specified *job* and report its termination status. If *job* is not given then all currently active child processes are waited for. The exit status from this command is that of the process waited for. See `Jobs` for a description of the format of *job*.

`whence [ -pv ] name . . .`

For each *name*, indicate how it would be interpreted if used as a command name.

The `-v` flag produces a more verbose report.

The `-p` flag does a path search for *name* even if *name* is an alias, a function, or a reserved word.

### Invocation

If the shell is invoked by `exec(2)`, and the first character of argument zero (`$0`) is `-`, then the shell is assumed to be a login shell and commands are read from `/etc/profile` and then from either `.profile` in the current directory or `$HOME/.profile`, if either file exists. Next, commands are read from the file named by performing parameter substitution on the value of the environment variable `ENV` if the file exists. If the `-s` flag is not present and *arg* is, then a path search is performed on the first *arg* to determine the name of the script to execute. The script *arg* must have read permission and any `setuid` and `setgid` settings will be ignored. If the script is not found on the path, *arg* is processed as if it named a builtin command or function. Commands are then read as described below; the following flags are interpreted by the shell when it is invoked:

- `-c` Read commands from the *command\_string* operand. Set the value of special parameter `0` from the value of the *command\_name* operand and the positional parameters (`$1`, `$2`, and so on) in sequence from the remaining *arg* operands. No commands will be read from the standard input.
- `-s` If the `-s` flag is present or if no arguments remain, commands are read from the standard input. Shell output, except for the output of the Special Commands listed above, is written to file descriptor 2.
- `-i` If the `-i` flag is present or if the shell input and output are attached to a terminal (as told by `ioctl(2)`), then this shell is *interactive*. In this case, `TERM` is ignored (so that `kill 0` does not kill an interactive shell) and `INTR` is caught and ignored (so that `wait` is interruptible). In all cases, `QUIT` is ignored by the shell.
- `-r` If the `-r` flag is present the shell is a restricted shell.

The remaining flags and arguments are described under the `set` command above.

### rksh Only

`rksh` is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. The actions of `rksh` are identical to those of `ksh`, except that the following are disallowed:

- changing directory (see `cd(1)`)
- setting the value of `SHELL`, `ENV`, or `PATH`
- specifying path or command names containing `/`

- redirecting output (>, >|, <>, and >>)
- changing group (see `newgrp(1)`).

The restrictions above are enforced after `.profile` and the `ENV` files are interpreted.

When a command to be executed is found to be a shell procedure, `rksh` invokes `ksh` to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the `.profile` has complete control over user actions, by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (that is, `/usr/rbin`) that can be safely invoked by `rksh`.

## ERRORS

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. Otherwise, the shell returns the exit status of the last command executed (see also the `exit` command above). If the shell is being used non-interactively then execution of the shell file is abandoned. Run time errors detected by the shell are reported by printing the command or function name and the error condition. If the line number that the error occurred on is greater than one, then the line number is also printed in square brackets (`[]`) after the command or function name.

For a non-interactive shell, an error condition encountered by a special built-in or other type of utility will cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

| Error                                          | Special Built-in | Other Utilities |
|------------------------------------------------|------------------|-----------------|
| Shell language syntax error                    | will exit        | will exit       |
| Utility syntax error (option or operand error) | will exit        | will not exit   |
| Redirection error                              | will exit        | will not exit   |
| Variable assignment error                      | will exit        | will not exit   |
| Expansion error                                | will exit        | will exit       |
| Command not found                              | n/a              | may exit        |
| Dot script not found                           | will exit        | n/a             |

An expansion error is one that occurs when the shell expansions are carried out (for example, `${x!y}`, because `!` is not a valid operator); an implementation may treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.

ksh(1)

If any of the errors shown as “will (may) exit” occur in a subshell, the subshell will (may) exit with a non-zero status, but the script containing the subshell will not exit because of the error.

In all of the cases shown in the table, an interactive shell will write a diagnostic message to standard error without exiting.

**USAGE** See `largefile(5)` for the description of the behavior of `ksh` and `rksh` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXIT STATUS** Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.

If a command is not found, the exit status will be 127. If the command name is found, but it is not an executable utility, the exit status will be 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.

If a command fails during word expansion or redirection, its exit status will be greater than zero.

When reporting the exit status with the special parameter `?`, the shell will report the full eight bits of exit status available. The exit status of a command that terminated because it received a signal will be reported as greater than 128.

Morris I. Bolsky and David G. Korn, *The KornShell Command and Programming Language*, Prentice Hall, 1989.

**WARNINGS** The use of `setuid` shell scripts is *strongly* discouraged.

**NOTES** If a command which is a *tracked alias* is executed, and then a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to `exec` the original command. Use the `-t` option of the `alias` command to correct this situation.

Some very old shell scripts contain a `^` as a synonym for the pipe character `|`.

Using the `fc` built-in command within a compound command will cause the whole command to disappear from the history file.

The built-in command `.file` reads the whole file before any commands are executed. Therefore, `alias` and `unalias` commands in the file will not apply to any functions defined in the file.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

| <b>DESCRIPTION</b>                              | The <code>ktutil</code> command is an interactive command-line interface utility for managing the keylist in keytab files. You must read in a keytab's keylist before you can manage it. Also, the user running the <code>ktutil</code> command must have read/write permissions on the keytab. For example, if a keytab is owned by root, which it typically is, <code>ktutil</code> must be run as root to have the appropriate permissions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <b>COMMANDS</b>                                 | <table><tr><td><code>clear_list, clear</code></td><td>Clears the current keylist.</td></tr><tr><td><code>read_kt file, rkt file</code></td><td>Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read.</td></tr><tr><td><code>write_kt file, wkt file</code></td><td>Writes the current keylist to a keytab <i>file</i>. You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file.</td></tr><tr><td><code>delete_entry number, delent number</code></td><td>Deletes an entry from the current keylist. Specify the entry by the keylist slot number.</td></tr><tr><td><code>list, l</code></td><td>Lists the current keylist.</td></tr><tr><td><code>list_request, lr</code></td><td>Lists available requests (commands).</td></tr><tr><td><code>quit, exit, q</code></td><td>Exits utility.</td></tr></table> | <code>clear_list, clear</code> | Clears the current keylist. | <code>read_kt file, rkt file</code> | Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read. | <code>write_kt file, wkt file</code> | Writes the current keylist to a keytab <i>file</i> . You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file. | <code>delete_entry number, delent number</code> | Deletes an entry from the current keylist. Specify the entry by the keylist slot number. | <code>list, l</code> | Lists the current keylist. | <code>list_request, lr</code> | Lists available requests (commands). | <code>quit, exit, q</code> | Exits utility. |
| <code>clear_list, clear</code>                  | Clears the current keylist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <code>read_kt file, rkt file</code>             | Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <code>write_kt file, wkt file</code>            | Writes the current keylist to a keytab <i>file</i> . You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <code>delete_entry number, delent number</code> | Deletes an entry from the current keylist. Specify the entry by the keylist slot number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <code>list, l</code>                            | Lists the current keylist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <code>list_request, lr</code>                   | Lists available requests (commands).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |

| <b>EXAMPLES</b>                                 | <p><b>EXAMPLE 1</b> Deleting a principal from a file</p> <p>The following example deletes the <code>host/denver@ACME.com</code> principal from the <code>/etc/krb5/krb5.keytab</code> file. Notice that if you want to delete an entry from an existing keytab, you must first write the keylist to a temporary keytab and then overwrite the existing keytab with the the temporary keytab. This is because the <code>wkt</code> command actually appends the current keylist to an existing keytab, so you can't use it to overwrite a keytab.</p> <pre>example# /usr/krb5/bin/ktutil ktutil: rkt /etc/krb5/krb5.keytab ktutil: list slot KVNO Principal ----- 1      8 host/vail@ACME.COM 2      5 host/denver@ACME.COM ktutil:delent 2 ktutil:l slot KVNO Principal ----- 1      8 host/vail@ACME.COM ktutil:wkt /tmp/krb5.keytab ktutil:q example# mv /tmp/krb5.keytab /etc/krb5/krb5.keytab</pre>                       |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |

**EXAMPLE 1** Deleting a principal from a file *(Continued)*

last(1)

**NAME** last – display login and logout information about users and terminals

**SYNOPSIS** **last** [-a] [-n *number* | -number] [-f *filename*] [*name* | *tty*...]

**DESCRIPTION** The **last** command looks in the `/var/adm/wtmpx` file, which records all logins and logouts, for information about a user, a terminal, or any group of users and terminals. Arguments specify names of users or terminals of interest. If multiple arguments are given, the information applicable to any of the arguments is printed. For example, `last root console` lists all of root's sessions, as well as all sessions on the console terminal. **last** displays the sessions of the specified users and terminals, most recent first, indicating the times at which the session began, the duration of the session, and the terminal on which the session took place. **last** also indicates whether the session is continuing or was cut short by a reboot.

The pseudo-user `reboot` logs in when the system reboots. Thus,

```
last reboot
```

will give an indication of mean time between reboots.

**last** with no arguments displays a record of all logins and logouts, in reverse order.

If **last** is interrupted, it indicates how far the search has progressed in `/var/adm/wtmpx`. If interrupted with a quit signal (generated by a CTRL-`\`), **last** indicates how far the search has progressed, and then continues the search.

**OPTIONS** The following options are supported:

- a Displays the hostname in the last column.
- f *filename* Uses *filename* as the name of the accounting file instead of `/var/adm/wtmpx`.
- n *number* | -*number* Limits the number of entries displayed to that specified by *number*. These options are identical; the -*number* option is provided as a transition tool only and will be removed in future releases.

**ENVIRONMENT VARIABLES** Date and time format is based on locale specified by the `LC_ALL`, `LC_TIME`, or `LANG` environments, in that order of priority.

**FILES** `/var/adm/wtmpx` accounting file

| <b>NAME</b>        | lastcomm – display the last commands executed, in reverse order                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>lastcomm</b> [-f <i>file</i> ] [-x] [ <i>command-name</i> ] ... [ <i>user-name</i> ] ... [ <i>terminal-name</i> ] ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>The <code>lastcomm</code> command gives information on previously executed commands. <code>lastcomm</code> with no arguments displays information about all the commands recorded during the current accounting file's lifetime. If called with arguments, <code>lastcomm</code> only displays accounting entries with a matching <i>command-name</i>, <i>user-name</i>, or <i>terminal-name</i>. If extended process accounting is active (see <code>acctadm(1M)</code>) and is recording the appropriate data items, <code>lastcomm</code> attempts to take data from the current extended process accounting file. If standard process accounting is active, <code>lastcomm</code> takes data from the current standard accounting file (see <code>acct(2)</code>).</p> <p>If <i>terminal-name</i> is '- -', there was no controlling TTY for the process. The process was probably executed during boot time. If <i>terminal-name</i> is '??', the controlling TTY could not be decoded into a printable name.</p> <p>For each process entry, <code>lastcomm</code> displays the following items of information:</p> <ul style="list-style-type: none"><li>■ The command name under which the process was called.</li><li>■ One or more flags indicating special information about the process. The flags have the following meanings:<ul style="list-style-type: none"><li>F           The process performed a fork but not an exec.</li><li>S           The process ran as a set-user-id program.</li></ul></li><li>■ The name of the user who ran the process.</li><li>■ The terminal which the user was logged in on at the time (if applicable).</li><li>■ The amount of CPU time used by the process (in seconds).</li><li>■ The date and time the process exited.</li></ul> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-f <i>file</i>           Uses <i>file</i> as the source of accounting data. <i>file</i> may be either an extended process accounting file or a standard process accounting file.</li><li>-x                   Uses the currently active extended process accounting file. If extended processing accounting is inactive, no output will be produced.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**EXAMPLE 2** Listing all user commands

The command

```
example% lastcomm root
```

produces a listing of all the commands executed by user root.

**FILES** /var/adm/pacct standard accounting file  
/var/adm/exacct/proc extended accounting file

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>NAME</b>        | ld – link-editor for object files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>DESCRIPTION</b> | <p>The <code>ld</code> command combines relocatable object files, performs relocation, and resolves external symbols. <code>ld</code> operates in two modes, static or dynamic, as governed by the <code>-d</code> option. In all cases, the output of <code>ld</code> is left in a <code>.out</code> by default. See NOTES.</p> <p>In static mode, <code>-dn</code>, relocatable object files given as arguments are combined to produce an executable object file. If the <code>-r</code> option is specified, relocatable object files are combined to produce one relocatable object file.</p> <p>In dynamic mode, <code>-dy</code>, the default, relocatable object files given as arguments are combined to produce an executable object file that will be linked at execution with any shared object files given as arguments. If the <code>-G</code> option is specified, relocatable object files are combined to produce a shared object.</p> <p>If any argument is a library, <code>ld</code> by default searches it exactly once at the point it encounters the library in the argument list. The library may be either a relocatable archive (see <code>ar(3HEAD)</code>) or a shared object.</p> <p>For an archive library, <code>ld</code> loads only those routines that define an unresolved external reference. <code>ld</code> searches the archive library symbol table sequentially with as many passes as are necessary to resolve external references that can be satisfied by library members. Thus, the order of members in the library is functionally unimportant, unless multiple library members exist that define the same external symbol. Archive libraries that have interdependencies may require multiple command-line definitions, or use of the <code>-z rescan</code> option.</p> <p>A shared object consists of an indivisible, whole unit that has been generated by a previous link-edit of one or more input files. When the link-editor processes a shared object, the entire contents of the shared object become a logical part of the resulting</p> |

output file image. The shared object is not physically copied during the link-edit as its actual inclusion is deferred until process execution. This logical inclusion means that all symbol entries defined in the shared object are made available to the link-editing process.

No command-line option is required to distinguish 32-bit or 64-bit objects. The link-editor uses the ELF class of the first input relocatable object file it sees on the command line to govern the mode in which it will operate. Intermixing 32-bit and 64-bit objects is not permitted. See also the `-64` option and the `LD_NOEXEC_64` environment variable.

**OPTIONS** The following options are supported:

`-64`

Creates a 64-bit object. By default, the class of the object being generated is determined from the first ELF object processed from the command line. This option is useful when creating an object directly with `ld` whose input is solely from a `mapfile` (see the `-M` option) or an archive library.

`-a`

In static mode only, produces an executable object file; gives errors for undefined references. This is the default behavior for static mode. `-a` may not be used with the `-r` option.

`-b`

In dynamic mode only, does no special processing for relocations that reference symbols in shared objects. Without the `-b` option, the link-editor creates special position-independent relocations for references to functions defined in shared objects and arranges for data objects defined in shared objects to be copied into the memory image of an executable by the runtime linker.

The `-b` option is intended for specialized dynamic objects and is not recommended for general use. Its use suppresses all specialized processing required to insure an object's shareability, and may even prevent the relocation of 64-bit executables.

`-B direct`

Establishes direct binding information by recording the relationship between each symbol reference and the dependency that provides the definition. The runtime linker uses this information to search directly for the symbol in the associated object rather than to carry out its default symbol search. Direct binding information can only be established to dependencies specified with the link-edit. Thus, you should use the `-z defs` option. Objects that wish to interpose on symbols in a direct binding environment should identify themselves as interposers with the `-z interpose` option. The use of `-B direct` enables `-z lazyload` for all dependencies.

`-B dynamic | static`

Options governing library inclusion. `-B dynamic` is valid in dynamic mode only. These options may be specified any number of times on the command line as toggles: if the `-B static` option is given, no shared objects will be accepted until `-B dynamic` is seen. See also the `-l` option.

ld(1)

**-B eliminate**

Causes any global symbols not assigned to a version definition to be eliminated from the symbol table. This option achieves the same symbol elimination as the *auto-elimination* directive available as part of a *mapfile* version definition.

**-B group**

Establishes a shared object and its dependencies as a group. Objects within the group will be bound to other members of the group at runtime. The runtime processing of an object containing this flag mimics that which occurs if the object is added to a process using `dlopen(3DL)` with the `RTLD_GROUP` mode. An object that has an explicit dependency on a object identified as a group, will itself become a member of the group.

As the group must be self contained, use of the `-B group` option also asserts the `-z defs` option.

**-B local**

Causes any global symbols, not assigned to a version definition, to be reduced to local. Version definitions can be supplied via a *mapfile* and indicate the global symbols that should remain visible in the generated object. This option achieves the same symbol reduction as the *auto-reduction* directive available as part of a *mapfile* version definition and may be useful when combining versioned and non-versioned relocatable objects.

**-B reduce**

When generating a relocatable object, causes the reduction of symbolic information defined by any version definitions. Version definitions can be supplied via a *mapfile* to indicate the global symbols that should remain visible in the generated object. When a relocatable object is generated, by default version definitions are only recorded in the output image. The actual reduction of symbolic information will be carried out when the object itself is used in the construction of a dynamic executable or shared object. This option is applied automatically when dynamic executable or shared object is created.

**-B symbolic**

In dynamic mode only. When building a shared object, binds references to global symbols to their definitions, if available, within the object. Normally, references to global symbols within shared objects are not bound until runtime, even if definitions are available, so that definitions of the same symbol in an executable or other shared object can override the object's own definition. `ld` will issue warnings for undefined symbols unless `-z defs` overrides.

The `-B symbolic` option is intended for specialized dynamic objects and is not recommended for general use. To reduce the runtime relocation overhead of an object, the creation of a version definition is recommended.

**-c name**

Records the configuration file *name* for use at runtime. Configuration files may be employed to alter default search paths, provide a directory cache and provide alternative object dependencies. See `crle(1)`.

- C  
Demangles C++ symbol names displayed in diagnostic messages.
- d y | n  
When -d y, the default, is specified, ld uses dynamic linking; when -d n is specified, ld uses static linking. See also -B dynamic | static.
- D token,...  
Prints debugging information, as specified by each *token*, to the standard error. The special token `help` indicates the full list of tokens available.
- e *epsym*  
Sets the entry point address for the output file to be that of the symbol *epsym*.
- f *name*  
Useful only when building a shared object. Specifies that the symbol table of the shared object is used as an auxiliary filter on the symbol table of the shared object specified by *name*. Multiple instances of this option are allowed. This option may not be combined with the -F option.
- F *name*  
Useful only when building a shared object. Specifies that the symbol table of the shared object is used as a filter on the symbol table of the shared object specified by *name*. Multiple instances of this option are allowed. This option may not be combined with the -f option.
- G  
In dynamic mode only, produces a shared object. Undefined symbols are allowed.
- h *name*  
In dynamic mode only, when building a shared object, records *name* in the object's dynamic section. *name* will be recorded in dynamic objects that are linked with this object rather than the object's file system name. Accordingly, *name* will be used by the runtime linker as the name of the shared object to search for at runtime.
- i  
Ignores LD\_LIBRARY\_PATH. This option is useful when an LD\_LIBRARY\_PATH setting is in effect to influence the runtime library search, which would interfere with the link-editing being performed.
- I *name*  
When building an executable, uses *name* as the path name of the interpreter to be written into the program header. The default in static mode is no interpreter; in dynamic mode, the default is the name of the runtime linker, `ld.so.1(1)`. Either case may be overridden by -I *name*. `exec(2)` will load this interpreter when it loads `a.out` and will pass control to the interpreter rather than to `a.out` directly.
- l x  
Searches a library `libx.so` or `libx.a`, the conventional names for shared object and archive libraries, respectively. In dynamic mode, unless the -B static option is in effect, ld searches each directory specified in the library search path for a `libx.so` or `libx.a` file. The directory search stops at the first directory containing either. ld chooses the file ending in `.so` if -lx expands to two files with names of

ld(1)

the form `libx.so` and `libx.a`. If no `libx.so` is found, then `ld` accepts `libx.a`. In static mode, or when the `-B static` option is in effect, `ld` selects only the file ending in `.a`. `ld` searches a library when it encounters its name, so the placement of `-l` is significant.

`-L path`

Adds *path* to the library search directories. `ld` searches for libraries first in any directories specified by the `-L` options and then in the standard directories. This option is useful only if it precedes the `-l` options to which it applies on the command line. The environment variable `LD_LIBRARY_PATH` may be used to supplement the library search path. See `LD_LIBRARY_PATH` below.

`-m`

Produces a memory map or listing of the input/output sections, together with any non-fatal multiply-defined symbols, on the standard output.

`-M mapfile`

Reads *mapfile* as a text file of directives to `ld`. This option may be specified multiple times. If *mapfile* is a directory, then all regular files, as defined by `stat(2)`, within the directory will be processed. See *Linker and Libraries Guide* for a description of mapfiles. There are mapfiles in `/usr/lib/ld` that show the default layout of programs, mapfiles for linking 64-bit programs above or below 4 gigabytes, and a mapfile for establishing a non-executable stack within an application. See the `FILES` section below.

`-N string`

This option causes a `DT_NEEDED` entry to be added to the `.dynamic` section of the object being built. The value of the `DT_NEEDED` string will be the *string* specified on the command line. This option is position dependent, and the `DT_NEEDED` `.dynamic` entry will be relative to the other dynamic dependencies discovered on the link-edit line. This option is useful for specifying dependencies within device driver relocatable objects when combined with the `-dy` and `-r` options.

`-o outfile`

Produces an output object file named *outfile*. The name of the default object file is `a.out`.

`-p auditlib`

Identifies an audit library, *auditlib*, that is used to audit this object at runtime. Any shared object identified as requiring auditing of itself has this requirement inherited by any object specifying this shared object as a dependency. See also the `-P` option.

`-P auditlib`

Identifies an audit library, *auditlib*, that is used to audit this object's dependencies at runtime. Dependency auditing can also be inherited from dependencies identified as requiring auditing. See also the `-p` option.

`-Q y | n`

Under `-Q y`, an `ident` string is added to the `.comment` section of the output file to identify the version of the link-editor used to create the file. This results in multiple

ld identifies when there have been multiple linking steps, such as when using ld -r. This is identical with the default action of the cc command. -Q n suppresses version identification.

- r  
Combines relocatable object files to produce one relocatable object file. ld will not complain about unresolved references. This option cannot be used with the -a option.
- R *path*  
A colon-separated list of directories used to specify library search directories to the runtime linker. If present and not NULL, it is recorded in the output object file and passed to the runtime linker. Multiple instances of this option are concatenated together with each *path* separated by a colon.
- s  
Strips symbolic information from the output file. Any debugging information, that is, .line, .debug\*, and .stab\* sections, and their associated relocation entries are removed. Except for relocatable files, a symbol table SHT\_SYMTAB and its associated string table section are not created in the output object file. See also -z redlocsym.
- S *supportlib*  
The shared object *supportlib* is loaded with the link-editor and given information regarding the linking process. Support shared objects may also be supplied using the SGS\_SUPPORT environment variable. See *Linker and Libraries Guide* for more details.
- t  
Turns off the warning for multiply-defined symbols that have different sizes or alignments.
- u *symname*  
Enters *symname* as an undefined symbol in the symbol table. This is useful for loading entirely from an archive library, since initially the symbol table is empty, and an unresolved reference is needed to force the loading of the first routine. The placement of this option on the command line is significant; it must be placed before the library that will define the symbol.
- V  
Outputs a message giving information about the version of ld being used.
- Y *P*, *dirlist*  
Changes the default directories used for finding libraries. *dirlist* is a colon-separated path list.
- z *absexec*  
Useful only when building a dynamic executable. Specifies that references to external absolute symbols should be resolved immediately instead of being left for resolution at runtime. In very specialized circumstances, this option removes text relocations that can result in excessive swap space demands by an executable.

ld(1)

`-z alleextract | defaultextract | weakextract`

Alters the extraction criteria of objects from any archives that follow. By default, archive members are extracted to satisfy undefined references and to promote tentative definitions with data definitions. Weak symbol references do not trigger extraction. Under `-z alleextract`, all archive members are extracted from the archive. Under `-z weakextract`, weak references trigger archive extraction. `-z defaultextract` provides a means of returning to the default following use of the former extract options.

`-z combrelloc`

Combines multiple relocation sections. Historically, relocation sections are maintained in a one-to-one relationship with the sections to which the relocations will be applied. When building an executable or shared object, ld sorts the entries of data relocation sections by their symbol reference so as to reduce runtime symbol lookup. Combining multiple data relocation sections allows optimal sorting and hence the least relocation overhead when objects are loaded into memory.

`-z defs | nodefs`

The `-z defs` option forces a fatal error if any undefined symbols remain at the end of the link. This is the default when an executable is built, but for historic reasons is *not* the default when building a shared object. Use of the `-z defs` option is recommended, as it assures the object being built is self-contained, that is, that all its symbolic references are resolved internally or to the object's immediate dependencies.

The `-z nodefs` option allows undefined symbols. For historic reasons, this is the default when a shared object is built. When used with executables, the behavior of references to such undefined symbols is unspecified. Use of the `-z nodefs` option is not recommended

`-z endfiltee`

Marks a filtee so that when processed by a filter it terminates any further filtee searches by the filter.

`-z finiarray=function`

Appends an entry to the `.finiarray` section of the object being built. If no `.finiarray` section is present, one is created. The new entry is initialized to point to *function*. See *Linker and Libraries Guide* for more details.

`-z groupperm | nogroupperm`

Assigns, or deassigns each dependency that follows to a unique group. Assigning a dependency to a group has the same effect as if the dependency had been built using the `-B group` option.

`-z ignore | record`

Ignores, or records, dynamic dependencies that are not referenced as part of the link-edit. Ignores, or records, unreferenced ELF sections from the relocatable objects input as part of the link-edit. By default, `-z record` is in effect.

An ELF section will be ignored, and hence eliminated, from the output file being generated if it contributes to an allocatable segment, if it provides no global symbols, and if no other section from any object that contributes to the link-edit makes reference to it.

**-z initarray=function**

Appends an entry to the `.initarray` section of the object being built. If no `.initarray` section is present, one is created. The new entry is initialized to point to *function*. See *Linker and Libraries Guide* for more details.

**-z initfirst**

Marks the object so that its runtime initialization occurs before the runtime initialization of any other objects brought into the process at the same time. In addition, the object runtime finalization will occur after the runtime finalization of any other objects removed from the process at the same time. This option is only meaningful when building a shared object.

**-z interpose**

Marks the object as an interposer. When direct bindings are in effect (see `-B direct`), the runtime linker will search for symbols in any interposers before the object associated to the direct binding.

**-z lazyload | nolazyload**

Enables or disables the marking of dynamic dependencies to be lazily loaded. Dynamic dependencies which are marked `lazyload` will not be loaded at initial process start-up, but instead will be delayed until the first binding to the object is made. *Note:* Lazy loading can require the correct declaration of dependencies and associated `runpaths` for each dynamic object used within a process. See *Linker and Libraries Guide* for more details.

**-z ld32=arg1,arg2,...**

**-z ld64=arg1,arg2,...**

The class of the link-editor is affected by the class of the output file being created and by the capabilities of the underlying operating system. This option provides a means of defining any link-editor argument, such that it will only be interpreted, respectively, by the 32- or 64-bit class of the link-editor.

For example, support libraries are class specific, so the correct class of support library can be insured using:

```
ld ... -z ld32=-Saudit32.so.1 -z ld64=-Saudit64.so.1 ...
```

*Note:* The class of link-editor invoked is in part determined from the ELF class of the first input relocatable file seen on the command line. This determination is carried out *prior* to any `-z ld[32|64]` processing.

**-z loadfltr**

Marks the object to require that when building a filter, its filtees be processed immediately at runtime. Normally, filter processing is delayed until a symbol reference is bound to the filter. The runtime processing of an object that contains this flag mimics that which occurs if the `LD_LOADFLTR` environment variable is in effect. See `ld.so.1(1)`.

ld(1)

- z muldefs  
Allows multiple symbol definitions. By default, multiple symbol definitions that occur between relocatable objects will result in a fatal error condition. This option suppresses the error condition and allows the first symbol definition to be taken.
- z nocompstrtab  
Disables the compression of ELF string tables.
- z nodefaultlib  
Marks the object so that the runtime default library search path (used after any LD\_LIBRARY\_PATH or runpaths) is ignored. This option implies that all dependencies of the object can be satisfied from its runpath.
- z nodelete  
Marks the object as non-deletable at runtime. The runtime processing of an object that contains this flag mimics that which occurs if the object is added to a process using dlopen(3DL) with the RTLD\_NODELETE mode.
- z nodlopen  
Marks the object as not available to dlopen(3DL), either as the object specified by the dlopen(), or as any form of dependency required by the object specified by the dlopen(). This option is only meaningful when building a shared object.
- z nodump  
Marks the object as not available to dldump(3DL).
- z nopartial  
If there are any partially initialized symbols in the input relocatable object files, the partially initialized symbols are expanded when the output file is generated.
- z noversion  
Does not record any versioning sections. Any version sections or associated .dynamic section entries will not be generated in the output image.
- z now  
Marks the object to override the runtime linker's default mode and require non-lazy runtime binding. This is similar to adding the object to the process by using dlopen(3DL) with the RTLD\_NOW mode, or setting the LD\_BIND\_NOW environment variable in effect. See ld.so.1(1).
- z origin  
Marks the object as requiring immediate \$ORIGIN processing at runtime. This option is only maintained for historic compatibility, as the runtime analysis of objects to provide for \$ORIGIN processing is now default.
- z preinitarray=*function*  
Appends an entry to the .preinitarray section of the object being built. If no .preinitarray section is present, one is created. The new entry is initialized to point to *function*. See *Linker and Libraries Guide* for more details.

**-z redlocsym**

Eliminates all local symbols except for the SECT symbols from the symbol table SHT\_SYMTAB. All relocations that refer to local symbols will be updated to refer to the corresponding SECT symbol.

**-z rescan**

Rescans the archive files provided to the link-edit. By default, archives are processed once as they appear on the command line. Archives are traditionally specified at the end of the command line so that their symbol definitions resolve any preceding references. However, it is often necessary to specify the archives multiple times to satisfy their own interdependencies.

The `-z rescan` option causes the entire archive list to be reprocessed in an attempt to locate additional archive members that resolve symbol references. This archive rescanning continues until a pass over the archive list occurs in which no new members are extracted.

**-z text**

In dynamic mode only, forces a fatal error if any relocations against non-writable, allocatable sections remain. For historic reasons, this is not the default when building an executable or shared object. However, its use is recommended to insure that the text segment of the dynamic object being built is shareable between multiple running processes, and that the object incurs the least relocation overhead when loaded into memory.

**-z textoff**

In dynamic mode only, allows relocations against all allocatable sections, including non-writable ones. This is the default when building a shared object.

**-z textwarn**

In dynamic mode only, lists a warning if any relocations against non-writable, allocatable sections remain. This is the default when building an executable.

**-z verbose**

This option provides additional warning diagnostics during a link-edit. Presently, its implementation conveys suspicious use of displacement relocations, but in future it may be enhanced to provide additional diagnostics deemed too noisy to be generated by default.

**ENVIRONMENT  
VARIABLES****LD\_LIBRARY\_PATH**

A list of directories in which to search for libraries specified with the `-l` option. Multiple directories are separated by a colon. In the most general case, it will contain two directory lists separated by a semicolon:

*dirlist1*; *dirlist2*

If `ld` is called with any number of occurrences of `-L`, as in:

`ld ... -Lpath1 ... -Lpathn ...`

then the search path ordering is:

*dirlist1* *path1* ... *pathn* *dirlist2* **LIBPATH**

ld(1)

When the list of directories does not contain a semicolon, it is interpreted as *dirlist2*.

The `LD_LIBRARY_PATH` environment variable also affects the runtime linkers searching for dynamic dependencies.

This environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to 32-bit or 64-bit processes and overrides any non-suffixed version of the environment variable that may be in effect.

#### `LD_NOEXEC_64`

Suppresses the automatic execution of the 64-bit link-editor. By default, the link-editor will execute its 64-bit version when the ELF class of the first input relocatable file it reads identifies it as a 64-bit object. Although there are some limitations to the 64-bit image that a 32-bit link-editor can create, some link-edits may find using the 32-bit link-editor faster.

#### `LD_OPTIONS`

A default set of options to `ld`. `LD_OPTIONS` is interpreted by `ld` just as though its value had been placed on the command line, immediately following the name used to invoke `ld`, as in:

```
ld $LD_OPTIONS ... other-arguments ...
```

#### `LD_RUN_PATH`

An alternative mechanism for specifying a `runpath` to the link-editor. See the `-R` option. If both `LD_RUN_PATH` and the `-R` option are specified, `-R` supersedes.

#### `SGS_SUPPORT`

Provides a colon-separated list of shared objects that are loaded with the link-editor and given information regarding the linking process. This environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to the 32-bit or 64-bit class of `ld` and overrides any non-suffixed version of the environment variable that may be in effect. See also the `-S` option.

Notice that environment variable-names beginning with the characters `'LD_'` are reserved for possible future enhancements to `ld` and `ld.so.1(1)`.

### FILES

`libx.so`  
shared object libraries.

`libx.a`  
archive libraries.

`a.out`  
default output file.

#### `LIBPATH`

`/usr/lib` for 32-bit libraries, or `/usr/lib/64` for 64-bit libraries.

`/usr/lib/ld/map.bssalign`  
mapfile providing a template for aligning bss.

/usr/lib/ld/map.default  
mapfile showing default layout of 32-bit programs.

/usr/lib/ld/map.noexstk  
mapfile showing a non-executable stack definition.

/usr/lib/ld/sparcv9/map.default  
mapfile showing default layout of 64-bit SPARCV9 programs.

/usr/lib/ld/sparcv9/map.above4G  
mapfile showing suggested layout above 4 gigabytes of 64-bit SPARCV9 programs.

/usr/lib/ld/sparcv9/map.below4G  
mapfile showing suggested layout below 4 gigabytes of 64-bit SPARCV9 programs.

*Linker and Libraries Guide*

**NOTES** Default options applied by `ld` are maintained for historic reasons. In today's programming environment, where dynamic objects dominate, alternative defaults would often make more sense. However, historic defaults must be maintained to insure compatibility with existing program development environments. Historic defaults are called out wherever possible in this manual. For a description of current recommended options, see the "Link-Editor Quick Reference" in the *Linker and Libraries Guide*.

If the file being created by `ld` already exists, it will be truncated after all input files have been processed and overridden with the new file contents. `ld` does not create a temporary file as part of the link-edit, since multiple instances of large output files frequently exhaust system resources. The drawback of overriding an existing file occurs if the file is in use by a running process. In this case, the process may be prematurely terminated as the output files image is created. This situation can be avoided by removing the output file before performing the link-edit. This removal is not detrimental to the running process, as it frees up the file system namespace, not the actual disk space, for the new output file creation. The disk space of a removed file is freed when the last process referencing the file terminates.

ld(1B)

**NAME** ld – link editor, dynamic link editor

**SYNOPSIS** /usr/ucb/ld [*options*]

**DESCRIPTION** /usr/ucb/ld is the link editor for the BSD Compatibility Package. /usr/ucb/ld is identical to /usr/ccs/bin/ld (see ld(1)) except that BSD libraries and routines are included *before* the base libraries and routines.

**OPTIONS** /usr/ucb/ld accepts the same options as /usr/ccs/bin/ld, with the following exceptions:

-L*dir* Add *dir* to the list of directories searched for libraries by /usr/ccs/bin/ld. Directories specified with this option are searched before /usr/ucb/lib and /usr/lib.

-Y LU,*dir* Change the default directory used for finding libraries. Warning: This option may have unexpected results, and should not be used.

**FILES** /usr/lib  
/usr/lib/libx.a  
/usr/ucb/lib  
/usr/ucb/lib/libx.a

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>NAME</b>        | ldap – LDAP as a naming repository                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>LDAP refers to Lightweight Directory Access Protocol, which is an industry standard for accessing directory servers. By initializing the client using <code>ldapclient(1M)</code> and using the keyword <code>ldap</code> in the name service switch file, <code>/etc/nsswitch.conf</code>, Solaris clients can obtain naming information from an LDAP server. Information such as usernames, hostnames, and passwords are stored on the LDAP server in a Directory Information Tree or DIT. The DIT consists of entries which in turn are composed of attributes. Each attribute has a type and one or more values.</p> <p>Solaris LDAP clients use the LDAP v3 protocol to access naming information from LDAP servers. The LDAP server must support the object classes and attributes defined in <i>RFC2307bis (draft)</i>, which maps the naming service model on to LDAP. As an alternate to using the schema defined in <i>RFC2307bis (draft)</i>, the system can be configured to use other schema sets and the schema mapping feature is configured to map between the two. Refer to the <i>System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)</i> for more details.</p> <p>The <code>ldapclient(1M)</code> utility can make a Solaris machine an LDAP client by setting up the appropriate directories, files, and configuration information. The LDAP client caches this configuration information in local cache files. This configuration information is accessed through the <code>ldap_cachemgr(1M)</code> daemon. This daemon also refreshes the information in the configuration files from the LDAP server, providing better performance and security. The <code>ldap_cachemgr</code> must run at all times for the proper operation of the naming services.</p> <p>There are two types of configuration information, the information available through a profile, and the information configured per client. The profile contains all the information as to how the client accesses the directory. The credential information for proxy user is configured on a per client basis and is not downloaded through the profile.</p> <p>The profile contains server-specific parameters that are required by all clients to locate the servers for the desired LDAP domain. This information could be the server's IP address and the search base Distinguished Name (DN), for instance. It is configured on the client from the default profile during client initialization and is periodically updated by the <code>ldap_cachemgr</code> daemon when the expiration time has elapsed.</p> <p>Client profiles can be stored on the LDAP server and may be used by the <code>ldapclient</code> utility to initialize an LDAP client. Using the client profile is the easiest way to configure a client machine. See <code>ldapclient(1M)</code>.</p> <p>Credential information includes client-specific parameters that are used by a client. This information could be the Bind DN (LDAP "login" name) of the client and the password. If these parameters are required, they are manually defined during the initialization through <code>ldapclient(1M)</code>.</p> <p>The naming information is stored in containers on the LDAP server. A container is a non-leaf entry in the DIT that contains naming service information. Containers are similar to maps in NIS and tables in NIS+. A default mapping between the NIS</p> |

## ldap(1)

databases and the containers in LDAP is presented below. The location of these containers as well as their names can be overridden through the use of `serviceSearchDescriptors`. For more information see `ldapclient(1M)`.

| Database         | Object Class                  | Container                 |

The security model for clients is defined by a combination of the credential level to be used, the authentication method, and the PAM module to be used, that is, `pam_unix` versus `pam_ldap`. The credential level defines what credentials the client should use to authenticate to the directory server, and the authentication method defines the method of choice. Both these can be set with multiple values. The Solaris LDAP supports the following values for credential level :

```
anonymous
proxy
```

The Solaris LDAP supports the following values for authentication method:

```
none
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

More protection can be provided by means of access control, allowing the server to grant access for certain containers or entries. Access control is specified by Access Control Lists (ACL's) that are defined and stored in the LDAP server. The Access Control Lists on the LDAP server are called Access Control Instructions (ACI's) by the the iPlanet Directory Server. Each ACL or ACI specifies one or more directory objects, for example, the cn attribute in a specific container, one or more clients to whom you grant or deny access, and one or more access rights that determine what the clients can do to or with the objects. Clients can be users or applications. Access rights can be specified as read and write, for example. Refer to the *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)* regarding the restrictions on ACL's and ACI's when using LDAP as a naming repository.

A sample `nsswitch.conf(4)` file called `nsswitch.ldap` is provided in the `/etc` directory. This is copied to `/etc/nsswitch.conf` by the `ldapclient(1M)` utility. This file uses LDAP as a repository for the different databases in the `nsswitch.conf` file.

The following is a list of the user commands related to LDAP:

```
idsconfig(1M) Prepares an iPlanet Directory Server to be ready to support
 Solaris LDAP clients.'

ldapaddent(1M) Create LDAP entries from corresponding /etc files.

ldapclient(1M) Initialize LDAP clients, or generate a configuration profile to be
 stored in the directory.

ldaplist(1) List the contents of the LDAP naming space.
```

## FILES

```
/var/ldap/ldap_client_cred
/var/ldap/ldap_client_file Files that contain the LDAP configuration of
 the client. Do not manually modify these
 files. Their content is not guaranteed to be
 human readable. Use ldapclient(1M) to
 update them.

/etc/nsswitch.conf Configuration file for the name-service
 switch
```

## ldap(1)

| <b>NAME</b>        | ldapdelete – ldap delete entry tool                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>ldapdelete</b> [-n] [-v] [-c] [-d <i>debuglevel</i> ] [-f <i>file</i> ] [-D <i>binddn</i> ]<br>[-w <i>passwd</i> ] [-h <i>ldaphost</i> ] [-M <i>authentication</i> ] [-p <i>ldapport</i> ] [ <i>dn...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | The <code>ldapdelete</code> utility opens a connection to an LDAP server, then binds and deletes one or more entries. If one or more <i>dn</i> arguments are provided, entries with those distinguished names are deleted. If no <i>dn</i> arguments are provided, a list of DN's is read from <i>file</i> , if the <code>-f</code> option is specified, or from standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li><code>-c</code> Continuous operation mode. Errors are reported, but <code>ldapdelete</code> will continue with deletions. The default is to exit after reporting an error.</li> <li><code>-d <i>debuglevel</i></code> Sets the LDAP debugging level. Useful levels of debugging for <code>ldapdelete</code> are: <ul style="list-style-type: none"> <li>1 Trace</li> <li>2 Packets</li> <li>4 Arguments</li> <li>32 Filters</li> <li>128 Access control</li> </ul> <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <i>debuglevel</i> of 33.</p> </li> <li><code>-D <i>binddn</i></code> Uses the distinguished name <i>binddn</i> to bind to the directory.</li> <li><code>-f <i>file</i></code> Reads the entry deletion information from <i>file</i> instead of from standard input.</li> <li><code>-h <i>ldaphost</i></code> Specifies an alternate host on which the slapd server is running.</li> <li><code>-M <i>authentication</i></code> Specifies the authentication mechanism used to bind to the directory. <p>The default authentication method for <code>ldapdelete</code> is <code>simple bind</code>. <code>simple bind</code> sends the password to the server in the clear. The password is subject to snooping if the server is not local. You must use special care when you use this command with the default authentication method. If your server supports the</p> </li> </ul> |

## ldapdelete(1)

challenge response method CRAM-MD5 authentication method, you can override the default authentication method by using the `-M` option with CRAM-MD5 as the value for *authentication*.

The bind DN and bind password are mandatory with this option.

- `-n` Shows what would be done, but does not actually delete entries. Useful in conjunction with options `-v` and `-d` for debugging.
- `-p ldapport` Specifies an alternate TCP port where the slapd server is listening.
- `-v` Uses verbose mode, with diagnostics written to standard output.
- `-w passwd` Use *passwd* as the password for authentication to the directory. When you use `-w passwd` to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files or in shell history. If you use the `ldapdelete` command without this option, the command will prompt for the password and read it from standard in. When used without the `-w` option, the password will not be visible to other users.

**OPERANDS** The following operand is supported:

`dn` Specifies one or several distinguished names of entries to delete.

**EXAMPLES** **EXAMPLE 1** Deleting an entry

To delete the entry named with commonName `Delete Me` directly below the XYZ Corporation organizational entry, use the following command:

```
example% ldapdelete -D "cn=Administrator, o=XYZ, c=US" \
"cn=Delete Me, o=XYZ, c=US"
```

**ATTRIBUTES** See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Evolving        |

**EXIT STATUS** The following exit values are returned:

ldapdelete(1)

|          |                                                                       |
|----------|-----------------------------------------------------------------------|
| 0        | Successful completion.                                                |
| Non-zero | An error occurred. A diagnostic message is written to standard error. |

| <b>NAME</b>        | <code>ldaplist</code> – search and list naming information from a LDAP directory using the configured profile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <code>/usr/bin/ldaplist [-dlv] [database [key] ...]</code><br><code>/usr/bin/ldaplist -h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The <code>ldaplist</code> utility searches for and lists the naming information from the LDAP directory service defined in the LDAP configuration files generated by <code>ldapclient(1M)</code> during the client initialization phase. The Solaris LDAP client must be set up in order to use this utility.</p> <p>The database is either a container name or a database name as defined in <code>nsswitch.conf(4)</code>. A container is a non-leaf entry in the Directory Information Tree (DIT) that contains naming service information. The container name is the LDAP Relative Distinguished Name (RDN) of the container relative to the <code>defaultSearchBase</code> as defined in the configuration files. For example, for a container named <code>ou=people</code>, the database name is the database specified in <code>nsswitch.conf</code>. This database is mapped to a container, for example, <code>passwd</code> maps to <code>ou=people</code>. If an invalid database is specified, it will be mapped to a generic container, for example, <code>nisMapName=name</code>.</p> <p>The key is the attribute value to be searched in the database. You can specify more than one key to be searched in the same database. The key can be specified in either of two forms: <code>attribute=value</code> or <code>value</code>. In the first case, <code>ldaplist</code> passes the search key to the server. In the latter case, an attribute is assigned depending on how the database is specified. If the database is a container name, then the "cn" attribute type is used. If it is a valid database name as defined in the <code>nsswitch.conf</code>, then a predefined attribute type is used (see table below). If it is an invalid database name, then <code>cn</code> is used as the attribute type.</p> <p>The <code>ldaplist</code> utility relies on the Schema defined in the <i>RFC 2307bis</i>, currently an IETF draft. The data stored on the LDAP server must be stored based on this Schema, unless the profile contains schema mapping definitions. For more information on schema mapping see <code>ldapclient(1M)</code>. The following table lists the default mapping from the database names to the container, the LDAP object class, and the attribute type used if not defined in the key.</p> |

| Database   | Object Class   | Attribute Type | Container         |
|------------|----------------|----------------|-------------------|
| aliases    | mailGroup      | cn             | ou=Aliases        |
| automount  | nisObject      | cn             | nisMapName=auto_* |
| bootparams | bootableDevice | cn             | ou=Ethers         |

- auto\_\* represents auto\_home, auto\_direct, ...
- If the key starts with a digit, it will be interpreted as an uid number.
- If the key starts with a non-digit, it will be interpreted as a host name.

The `ldaplist` utility supports substring search by using the wildcard "\*" in the key. For example, "my\*" will match any strings that starts with "my". In some shell environments, keys containing the wildcard may need to be quoted.

If the key is not specified, all the containers in the current search `baseDN` will be listed.

## OPTIONS

The following options are supported:

- d Lists the attributes for the specified database, rather than the entries. By default, the entries are listed.
- h Lists the database mapping.
- l Lists all the attributes for each entry matching the search criteria. By default, `ldaplist` lists only the Distinguished Name of the entries found.

## ldaplist(1)

**-v** Sets verbose mode. The `ldaplist` utility will also print the filter used to search for the entry. The filter will be prefixed with "+++".

### EXAMPLES

**EXAMPLE 1** Listing All Entries in the `hosts` Database

```
example% ldaplist hosts
```

**EXAMPLE 2** Listing All Entries in a Non-Standard Database `ou=new`

```
example% ldaplist ou=new
```

**EXAMPLE 3** Finding "user1" in the `passwd` Database

```
example% ldaplist passwd user1
```

**EXAMPLE 4** Finding the Entry With Service Port of 4045 in the `services` Database

```
example% ldaplist services ipServicePort=4045
```

**EXAMPLE 5** Finding All Users With Username Starting with `new` in the `passwd` Database

```
example% ldaplist passwd 'new*'
```

**EXAMPLE 6** Listing the Attributes for the `hosts` Database

```
example% ldaplist -d hosts
```

### EXIT STATUS

The following exit values are returned:

- 0 Successfully matched some entries.
- 1 Successfully searched the table and no matches were found.
- 2 An error occurred. An error message is output.

### FILES

`/var/ldap/ldap_client_file`  
`/var/ldap/ldap_client_cred`

Files that contain the LDAP configuration of the client. Do not manually modify these files. Their content is not guaranteed to be human readable. To update these files, use `ldapclient(1M)`

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWnisu        |
| Interface Stability | Evolving        |

ldaplist(1)

| <b>DESCRIPTION</b> | <p>The <code>ldapmodify</code> utility opens a connection to an LDAP server, binds and modifies or adds entries. The entry information is read from standard input or from <i>file</i>, specified using the <code>-f</code> option. The <code>ldapadd</code> utility is implemented as a hard link to the <code>ldapmodify</code> tool. When invoked as <code>ldapadd</code>, the <code>-a</code> (add new entry) option is turned on automatically.</p> <p>Both <code>ldapadd</code> and <code>ldapmodify</code> reject duplicate attribute-name/value pairs for the same entry.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-a Adds new entries. The default for <code>ldapmodify</code> is to modify existing entries. If invoked as <code>ldapadd</code>, this option is always set.</li><li>-c Specifies continuous operation mode. Errors are reported, but <code>ldapmodify</code> and <code>ldapadd</code> continue with modifications. The default is to exit after reporting an error.</li><li>-D <i>binddn</i> Uses the distinguished name <i>binddn</i> to bind to the directory.</li><li>-d <i>debuglevel</i> Sets the LDAP debugging level. Useful levels of debugging for <code>ldapmodify</code> and <code>ldapadd</code> are:<ul style="list-style-type: none"><li>1 Trace</li><li>2 Packets</li><li>4 Arguments</li><li>32 Filters</li><li>128 Access control</li></ul>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <i>debuglevel</i> of 33.</li><li>-F Forces application of all changes regardless of the content of input lines that begin with <code>replica:</code>. By default, <code>replica:</code> lines are compared against the LDAP server host and port in use to decide whether a relog record should be applied.</li></ul> |

## ldapmodify(1)

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-f file</code>                | Reads the entry modification information from <i>file</i> instead of from standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-h ldaphost</code>            | Specifies an alternate host on which the slapd server is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-l nb-ldap-connections</code> | Specifies the number of LDAP connections that <code>ldapadd</code> or <code>ldapmodify</code> will open to process the modifications in the directory. The default is one connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-M authentication</code>      | <p>Specifies the authentication mechanism used to bind to the directory.</p> <p>The default authentication method for <code>ldapmodify</code> and <code>ldapadd</code> is <code>simple bind</code>. <code>simple bind</code> sends the password to the server in the clear. The password is subject to snooping if the server is not local. You must use special care when you use this command with the default authentication method. If your server supports the challenge response method <code>CRAM-MD5</code> authentication method, you can override the default authentication method by using the <code>-M</code> option with <code>CRAM-MD5</code> as the value for <i>authentication</i>.</p> <p>The bind DN and bind password are mandatory with this option.</p> |
| <code>-n</code>                     | Previews modifications, but makes no changes to entries. Useful in conjunction with <code>-v</code> and <code>-d</code> for debugging.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-p ldapport</code>            | Specifies an alternate TCP port where the slapd server is listening.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-r</code>                     | Replaces existing value with the specified value. This is the default for <code>ldapmodify</code> . When <code>ldapadd</code> is called, or if the <code>-a</code> option is specified, the <code>-r</code> option is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-v</code>                     | Uses verbose mode, with diagnostics written to standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-w passwd</code>              | Use <i>passwd</i> as the password for authentication to the directory. When you use <code>-w passwd</code> to specify the password to be used for authentication, the password is visible to other users of the system by means of the <code>ps</code> command, in script files or in shell history. If you use either the <code>ldapmodify</code> command or the <code>ldapadd</code> command without this option, the command will prompt for the password and read it from standard in.                                                                                                                                                                                                                                                                                    |

## ldapmodify(1)

When used without the `-w` option, the password will not be visible to other users.

### EXIT STATUS

The following exit values are returned:

- |          |                                                                       |
|----------|-----------------------------------------------------------------------|
| 0        | Successful completion.                                                |
| Non-zero | An error occurred. A diagnostic message is written to standard error. |

### EXAMPLES

The format of the content of *file* (or standard input if no `-f` option is specified) is illustrated in the following examples.

#### EXAMPLE 1 Modifying an entry

The file `/tmp/entrymods` contains the following modification instructions:

```
dn: cn=Modify Me, o=XYZ, c=US
changetype: modify
replace: mail
mail: modme@atlanta.xyz.com
-
add: title
title: System Manager
-
add: jpegPhoto
jpegPhoto:< file:///tmp/modme.jpeg
-
delete: description
-
```

The command:

```
example% ldapmodify -r -f /tmp/entrymods
```

modifies the `Modify Me` entry as follows:

1. The current value of the `mail` attribute is replaced with the value, `modme@atlanta.xyz.com`.
2. A `title` attribute with the value, `System Manager`, is added.
3. A `jpegPhoto` attribute is added, using the contents of the file, `/tmp/modme.jpeg`, as the attribute value.
4. The `description` attribute is removed.

#### EXAMPLE 2 Creating a new entry

The file, `/tmp/newentry`, contains the following information for creating a new entry:

```
dn: cn=Ann Jones, o=XYZ, c=US
objectClass: person
cn: Ann Jones
cn: Annie Jones
```

**EXAMPLE 2** Creating a new entry (Continued)

```
sn: Jones
title: Director of Research and Development
mail: ajones@londonrd.xyz.us.com
uid: ajones
```

The command

```
example% ldapadd -f /tmp/newentry
```

adds a new entry for Ann Jones, using the information in the file.

**EXAMPLE 3** Deleting an entry

The file, /tmp/badentry, contains the following information about an entry to be deleted:

```
dn: cn=Ann Jones, o=XYZ, c=US
changetype: delete
```

The command:

```
example% ldapmodify -f /tmp/badentry
```

removes Ann Jones' entry.

**ATTRIBUTES**

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Evolving        |

| <b>NAME</b>        | ldapmodrdn – ldap modify entry RDN tool                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |       |   |         |   |           |    |         |     |                |
| <b>SYNOPSIS</b>    | <b>ldapmodrdn</b> [-r] [-n] [-v] [-c] [-d <i>debuglevel</i> ] [-D <i>binddn</i> ] [-w <i>passwd</i> ]<br>[-h <i>ldaphost</i> ] [-M <i>authentication</i> ] [-p <i>ldapport</i> ] [-f <i>file</i> ] [ <i>dn rdn</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |   |       |   |         |   |           |    |         |     |                |
| <b>DESCRIPTION</b> | ldapmodrdn opens a connection to an LDAP server, binds, and modifies the RDN of entries. The entry information is read from standard input, from <i>file</i> through the use of the -f option, or from the command-line pair <i>dn</i> and <i>rdn</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |       |   |         |   |           |    |         |     |                |
| <b>OPTIONS</b>     | <p>-c Continuous operation mode. Errors are reported, but ldapmodify continues with modifications. The default is to exit after reporting an error.</p> <p>-D <i>binddn</i> Use the distinguished name <i>binddn</i> to bind to the directory.</p> <p>-d <i>debuglevel</i> Set the LDAP debugging level. Useful values of <i>debuglevel</i> for ldapmodrdn are:</p> <table><tr><td>1</td><td>Trace</td></tr><tr><td>2</td><td>Packets</td></tr><tr><td>4</td><td>Arguments</td></tr><tr><td>32</td><td>Filters</td></tr><tr><td>128</td><td>Access control</td></tr></table> <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <i>debuglevel</i> of 33.</p> <p>-f <i>file</i> Read the entry modification information from <i>file</i> instead of from standard input or the command-line.</p> <p>-h <i>ldaphost</i> Specify an alternate host on which the slapd server is running.</p> <p>-M <i>authentication</i> Specifies the authentication mechanism used to bind to the directory.</p> <p>The default authentication method for ldapmodrdn is simple bind. simple bind sends the password to the server in the clear. The password is subject to snooping if the server is not local. You must use special care when you use this command with the default authentication method. If your server supports the challenge response method CRAM-MD5 authentication method, you can override the default authentication method by using the -M option with CRAM-MD5 as the value for <i>authentication</i>.</p> | 1 | Trace | 2 | Packets | 4 | Arguments | 32 | Filters | 128 | Access control |
| 1                  | Trace                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |       |   |         |   |           |    |         |     |                |

| 32                 | Filters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |       |   |         |   |           |    |         |     |                |
| 128                | Access control                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |       |   |         |   |           |    |         |     |                |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | The bind DN and bind password are mandatory with this option.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -n                  | Show what would be done, but don't actually change entries. Useful in conjunction with -v for debugging.                                                                                                                                                                                                                                                                                                                                                                                          |
| -p <i>ldappport</i> | Specify an alternate TCP port where the slapd server is listening.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -r                  | Remove old RDN values from the entry. By default, old values are kept.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -v                  | Use verbose mode, with diagnostics written to standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -w <i>passwd</i>    | Use <i>passwd</i> as the password for authentication to the directory. When you use -w <i>passwd</i> to specify the password to be used for authentication, the password is visible to other users of the system by means of the ps command, in script files or in shell history. If you use the ldapmodrdn command without this option, the command will prompt for the password and read it from standard in. When used without the -w option, the password will not be visible to other users. |

**Input Format** If the command-line arguments *dn* and *rdn* are given, *rdn* replaces the RDN of the entry specified by the DN, *dn*.

Otherwise, the contents of *file* (or standard input if the -f option is not specified) must consist of one or more pair of lines:

```
Distinguished Name (DN)
Relative Distinguished Name (RDN)
```

Use one or more blank lines to separate each DN/RDN pair.

**EXAMPLES** The file /tmp/entrymods contains:

```
cn=Modify Me, o=XYZ, c=US
cn=The New Me
```

The command:

```
example% ldapmodify -r -f /tmp/entrymods
```

changes the RDN of the "Modify Me" entry from "Modify Me" to "The New Me" and the old cn, "Modify Me" is removed.

**ATTRIBUTES** See attributes(5) for a description of the following attributes:

ldapmodrdn(1)

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Evolving        |

**SEE ALSO** ldapadd(1), ldapdelete(1), ldapmodify(1), ldapsearch(1), attributes(5)

**DIAGNOSTICS** Exit status is 0 if no errors occur. Errors result in a non-zero exit status and a diagnostic message being written to standard error.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>DESCRIPTION</b>   | <p>ldapsearch opens a connection to an LDAP server, binds, and performs a search using the filter <i>filter</i>.</p> <p>If ldapsearch finds one or more entries, the attributes specified by <i>attrs</i> are retrieved and the entries and values are printed to standard output. If no <i>attrs</i> are listed, all attributes are returned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Output Format</b> | <p>If one or more entries are found, each entry is written to standard output in the form:</p> <pre> Distinguished Name (DN)   User Friendly Name (if the -u option is used)   attributename=value   attributename=value   attributename=value   . . . </pre> <p>Multiple entries are separated with a single blank line. If the -F option is used to specify a different separator character, this character will be used instead of the '=' character. If the -t option is used, the name of a temporary file is returned in place of the actual value. If the -A option is given, only the "attributename" is returned and not the attribute value.</p>                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>       | <p>-A Retrieve attributes only (no values). This is useful when you just want to see whether an attribute is present in an entry and are not interested in the specific value.</p> <p>-a <i>deref</i> Specify how aliases dereferencing is done. The possible values for <i>deref</i> are <i>never</i>, <i>always</i>, <i>search</i>, or <i>find</i> to specify respectively that aliases are never dereferenced, always dereferenced, dereferenced when searching, or dereferenced only when finding the base object for the search. The default is to never dereference aliases.</p> <p>-B Do not suppress display of non-ASCII values. This is useful when dealing with values that appear in alternate character sets such as ISO-8859.1. This option is automatically set by the -L option.</p> <p>-b <i>searchbase</i> Use <i>searchbase</i> as the starting point for the search instead of the default.</p> <p>-D <i>binddn</i> Use the distinguished name <i>binddn</i> to bind to the directory.</p> |

| <code>-M <i>authentication</i></code> | <p>Specifies the authentication mechanism used to bind to the directory.</p> <p>The default authentication method for <code>ldapsearch</code> is <code>simple bind</code>. <code>simple bind</code> sends the password to the server in the clear. The password is subject to snooping if the server is not local. You must use special care when you use this command with the default authentication method. If your server supports the challenge response method <code>CRAM-MD5</code> authentication method, you can override the default authentication method by using the <code>-M</code> option with <code>CRAM-MD5</code> as the value for <i>authentication</i>.</p> <p>The bind DN and bind password are mandatory with this option.</p> |   |       |   |         |   |           |    |         |     |                |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -n                  | Show what would be done, but do not actually perform the search. Useful in conjunction with -v and -d for debugging.                                                                                                                                                                                                                                                                                                                                                                                            |
| -p <i>ldapport</i>  | Specify an alternate TCP port where the slapd server is listening.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| -R                  | Do not automatically follow referrals returned while searching.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -s <i>scope</i>     | Specify the scope of the search. The possible values of <i>scope</i> are <i>base</i> , <i>one</i> , or <i>sub</i> to specify respectively a base object, one-level, or subtree search. The default is <i>sub</i> .                                                                                                                                                                                                                                                                                              |
| -t                  | Write retrieved values to a set of temporary files. This is useful for dealing with non-ASCII values such as <i>jpegPhoto</i> or <i>audio</i> .                                                                                                                                                                                                                                                                                                                                                                 |
| -u                  | Include the user-friendly form of the Distinguished Name (DN) in the output.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -v                  | Run in verbose mode, with diagnostics written to standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -w <i>passwd</i>    | Use <i>passwd</i> as the password for authentication to the directory. When you use -w <i>passwd</i> to specify the password to be used for authentication, the password is visible to other users of the system by means of the <i>ps</i> command, in script files or in shell history. If you use the <i>ldapsearch</i> command without this option, the command will prompt for the password and read it from standard in. When used without the -w option, the password will not be visible to other users. |
| -z <i>sizelimit</i> | Retrieve at most <i>sizelimit</i> entries for a search to complete.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**EXAMPLES**    **EXAMPLE 1** Performing a Subtree Search

The following command performs a subtree search (using the default search base) for entries with a *commonName* of "mark smith". The *commonName* and *telephoneNumber* values will be retrieved and printed to standard output.

```
example% ldapsearch "cn=mark smith" cn telephoneNumber
```

The output looks something like this:

```
cn=Mark D Smith, ou=Sales, ou=Atlanta, ou=People, o=XYZ, c=US
cn=Mark Smith
cn=Mark David Smith
cn=Mark D Smith 1
cn=Mark D Smith
```

## ldapsearch(1)

### **EXAMPLE 1** Performing a Subtree Search (Continued)

```
telephoneNumber=+1 123 456-7890
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
cn=Mark Smith
cn=Mark C Smith 1
cn=Mark C Smith
telephoneNumber=+1 123 456-9999
```

### **EXAMPLE 2** Performing a Subtree Search Using the Default Search Base

The following command performs a subtree search using the default search base for entries with user id of "mcs". The user-friendly form of the entry's DN will be output after the line that contains the DN itself, and the jpegPhoto and audio values will be retrieved and written to temporary files.

```
example%ldapsearch -u -t "uid=mcs" jpegPhoto audio
```

The output might look like this if one entry with one value for each of the requested attributes is found:

```
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
Mark C Smith, Distribution, Atlanta, People, XYZ, US
audio=/tmp/ldapsearch-audio-a19924
jpegPhoto=/tmp/ldapsearch-jpegPhoto-a19924
```

### **EXAMPLE 3** Performing a One Level Search

The following command performs a one-level search at the c=US level for all organizations whose organizationName begins with XY.

```
example% ldapsearch -L -s one -b "c=US" "o=XY*" o description
```

Search results are displayed in the LDIF format. The organizationName and description attribute values will be retrieved and printed to standard output, resulting in output similar to this:

```
dn: o=XYZ, c=US
o: XYZ
description: XYZ Corporation
dn: o="XY Trading Company", c=US
o: XY Trading Company
description: Import and export specialists

dn: o=XYInternational, c=US
o: XYInternational
o: XYI
o: XY International
```

**EXIT STATUS** The following exit values are returned:

```
0 Successful completion.
```

ldapsearch(1)

>0 An error occurred. A diagnostic message is written to standard error.

**ATTRIBUTES** See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Evolving        |

**SEE ALSO** `ldapadd(1)`, `ldapdelete(1)`, `ldapmodify(1)`, `ldapmodrdn(1)`, `attributes(5)`

| <b>NAME</b>        | ldd – list dynamic dependencies of executable files or shared objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <b>ldd</b> [-d   -r] [-c] [-e <i>envvar</i> ] [-f] [-i] [-L] [-l] [-s] [-U   -u] [-v] <i>filename...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>ldd</code> utility lists the dynamic dependencies of executable files or shared objects. <code>ldd</code> uses the runtime linker, <code>ld.so.1</code>, to generate the diagnostics, since it takes the object being inspected and prepares it as it would in a running process. By default, <code>ldd</code> triggers the loading of any lazy dependencies.</p> <p><code>ldd</code> lists the path names of all shared objects that will be loaded when <i>filename</i> is loaded. <code>ldd</code> expects shared objects to have execute permission. If this is not the case, <code>ldd</code> will issue a warning before attempting to process the file.</p> <p><code>ldd</code> processes its input one file at a time. For each input file, <code>ldd</code> performs one of the following:</p> <ul style="list-style-type: none"><li>■ Lists the object dependencies if they exist.</li><li>■ Succeeds quietly if dependencies do not exist.</li><li>■ Prints an error message if processing fails.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p><code>ldd</code> can also check the compatibility of <i>filename</i> with the shared objects it uses. With each of the following options, <code>ldd</code> prints warnings for any unresolved symbol references that would occur when <i>filename</i> is loaded.</p> <p>-d           Check <i>immediate</i> references.</p> <p>-r           Check both <i>immediate</i> and <i>lazy</i> references.</p> <p>Only one of the above options can be specified during any single invocation of <code>ldd</code>. <i>immediate</i> references are typically to data items used by the executable or shared object code, pointers to functions, and even calls to functions made from a position <i>dependent</i> shared object. <i>lazy</i> references are typically calls to global functions made from a position <i>independent</i> shared object, or calls to external functions made from an executable. For more information on these types of reference, see “When Relocations Are Performed” in the <i>Linker and Libraries Guide</i>. Object loading can also be affected by relocation processing. See <i>Lazy Loading</i> under <i>USAGE</i> for more details.</p> <p><code>ldd</code> can also check dependency use. With each of the following options, <code>ldd</code> prints warnings for any unreferenced or unused dependencies that are loaded when <i>filename</i> is loaded. Only when a symbol reference is bound to a dependency, is that dependency deemed used. These options are therefore only useful when symbol references are being checked. If the <code>-r</code> option is not in effect, the <code>-d</code> option is enabled.</p> <p>A dependency that is defined by an object but is not bound to from that object is an unreferenced dependency. A dependency that is not bound to by any other object when <i>filename</i> is loaded is an unused object.</p> <p>-U           Displays any unreferenced or unused dependencies. If an unreferenced dependency is not bound to by other objects loaded with <i>filename</i>, it is also</p> |

flagged as unused. Cyclic dependencies that are not bound to from objects outside of the cycle are also deemed unreferenced.

**-u** Displays any unused objects.

Only one of the above options can be specified during any single invocation of `ldd`, although `-U` is a superset of `-u`. Objects that are found to be unreferenced or unused when using the `-r` option should be removed as dependencies. They provide no references but result in unnecessary overhead when *filename* is loaded. Objects that are found to be unreferenced or unused when using the `-d` option are not immediately required when *filename* is loaded, and are therefore candidates for lazy loading. See *Lazy Loading* under *USAGE* for more details.

The removal of unused dependencies reduces runtime linking overhead. The removal of unreferenced dependencies reduces runtime linking overhead to a lesser degree, but also guards against a dependency becoming unused when combined with different objects, or as the other object dependencies evolve.

The following additional options are supported:

- c** Disables any configuration file use. Configuration files may be employed to alter default search paths, provide a directory cache, and provide alternative object dependencies. See *crle(1)*.
- e *envvar*** Sets the environment variable *envvar*. This option is useful for experimenting with runtime linker environment variables that can adversely affect `ldd` itself.
- f** Forces `ldd` to check for an executable file that is not secure. When `ldd` is invoked by a superuser, by default it will not process any executable that it finds not secure. An executable is not considered secure if the interpreter it specifies does not reside under `/usr/lib` or `/etc/lib`, or if the interpreter cannot be determined. See *Security* under *USAGE*.
- i** Displays the order of execution of initialization sections. The order discovered may be affected by use of the `-d` or `-r` options. See *Initialization Order* under *USAGE*.
- L** Enables lazy loading. This is the default mode of operation when the object under inspection is loaded as part of a process. In this case, any lazy dependencies, or filters, are only loaded into the process when reference is made to a symbol that is defined within the lazy object. The `-d` or `-r` options, together with the `-L` option, may be used to inspect the dependencies and their order of loading since it will occur in a running process.
- l** Forces the immediate processing of any filters so that all filtees, and their dependencies, are listed. The immediate processing of filters is now the default mode of operation for `ldd`. However,

## ldd(1)

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>-s</code>     | Displays the search path used to locate shared object dependencies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-v</code>     | Displays all dependency relationships incurred when processing <i>filename</i> . This option also displays any dependency version requirements. See <code>pvs(1)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Security</b>     | <p>A superuser should use the <code>-f</code> option only if the executable to be examined is known to be trustworthy, because use of <code>-f</code> on an untrustworthy executable while superuser may compromise system security. If it is unknown whether or not the executable to be examined is trustworthy, a superuser should temporarily become a regular user and invoke <code>ldd</code> as that regular user.</p> <p>Untrustworthy objects can be safely examined with <code>dump(1)</code> and with <code>adb(1)</code>, as long as the <code>:r</code> subcommand is not used. In addition, a non-superuser can use either the <code>:r</code> subcommand of <code>adb</code> or <code>truss(1)</code> to examine an untrustworthy executable without too much risk of compromise. To minimize risk when using <code>ldd</code>, <code>adb :r</code>, or <code>truss</code> on an untrustworthy executable, use the user id "nobody".</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Lazy Loading</b> | <p>Objects that employ lazy loading techniques, either through directly specified lazy dependencies (see the <code>-z lazyload</code> option of <code>ld(1)</code>), or through filters (see the <code>-f</code> and <code>-F</code> options of <code>ld(1)</code>), may experience variations in <code>ldd</code> output due to the options they use. If an object expresses all its dependencies as lazy, the default operation of <code>ldd</code> will list all dependencies in the order in which they are recorded in that object:</p> <pre>example% ldd main libelf.so.1 =&gt; /usr/lib/libelf.so.1 libnsl.so.1 =&gt; /usr/lib/libnsl.so.1 libc.so.1 =&gt; /usr/lib/libc.so.1</pre> <p>The lazy loading behavior that occurs when this object is used at runtime may be enabled using the <code>-L</code> option. In this mode, lazy dependencies are loaded when reference is made to a symbol that is defined within the lazy object. Therefore, combining the <code>-L</code> option with use of the <code>-d</code> and <code>-r</code> options will reveal the dependencies needed to satisfy the immediate and lazy references respectively:</p> <pre>example% ldd -L main example% ldd -d main libc.so.1 =&gt; /usr/lib/libc.so.1 example% ldd -r main libc.so.1 =&gt; /usr/lib/libc.so.1 libelf.so.1 =&gt; /usr/lib/libelf.so.1</pre> <p>Notice that in this example, the order of the dependencies listed is not the same as displayed from <code>ldd</code> with no options, and even with the <code>-r</code> option, the lazy reference to dependencies may not occur in the same order as it will in a running program.</p> |

**Initialization  
Order**

Observing lazy loading may also reveal objects that are not required to satisfy any references. These objects (in this example, `libns1.so.1`) are candidates for removal from the link-line used to build the object being inspected.

Objects that do not explicitly define their required dependencies may observe variations in the initialization section order displayed by `ldd` due to the options they use. For example, a simple application may reveal:

```
example% ldd -i main
libA.so.1 => ./libA.so.1
libc.so.1 => /usr/lib/libc.so.1
libB.so.1 => ./libB.so.1

init object=./libB.so.1
init object=./libA.so.1
init object=/usr/lib/libc.so.1
```

whereas, when relocations are applied, the initialization section order is:

```
example% ldd -ir main
.....

init object=/usr/lib/libc.so.1
init object=./libB.so.1
init object=./libA.so.1
```

In this case, `libB.so.1` makes reference to a function in `/usr/lib/libc.so.1`. However, it has no explicit dependency on this library. Only after a relocation is discovered is a dependency established, which in turn affects the initialization section sort order.

Typically, the initialization section sort order established when an application is executed is equivalent to `ldd` with the `-d` option. The optimum order can be obtained if all objects fully define their dependencies. Use of the `ld(1)` options `-z defs` and `-z ignore` when building dynamic objects is recommended.

Cyclic dependencies may result when one or more dynamic objects reference each other. Cyclic dependencies should be avoided, as a unique initialization sort order for these dependencies can not be established.

Users that prefer a more static analysis of object files may inspect dependencies using tools such as `dump(1)` and `elfdump(1)`.

*Linker and Libraries Guide*

**DIAGNOSTICS** `ldd` prints the record of shared object path names to `stdout`. The optional list of symbol resolution problems is printed to `stderr`. If *filename* is not an executable file or a shared object, or if it cannot be opened for reading, a non-zero exit status is returned.

**NOTES** `ldd` does not list shared objects explicitly attached using `dlopen(3DL)`.

Using the `-d` or `-r` option with shared objects can give misleading results. `ldd` does a "worst case" analysis of the shared objects. However, in practice some or all of the symbols reported as unresolved can be resolved by the executable file referencing the shared object. The runtime linker preloading mechanism (see `LD_PRELOAD`) may be employed to add dependencies to the object being inspected.

`ldd` uses the same algorithm as the runtime linker to locate shared objects.

| <b>NAME</b>        | ld.so.1 – runtime linker for dynamic objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre><b>/usr/lib/ld.so.1</b> <b>/etc/lib/ld.so.1</b></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>Dynamic applications consist of one or more dynamic objects. They are typically a dynamic executable and its shared object dependencies. As part of the initialization and execution of a dynamic application, an <i>interpreter</i> is called. This interpreter completes the binding of the application to its shared object dependencies. In Solaris, this interpreter is referred to as the runtime linker.</p> <p>During the link-editing of a dynamic executable, a special <code>.interp</code> section, together with an associated program header, is created. This section contains a pathname specifying the program's interpreter. An interpreter pathname can be specified when the executable is constructed using the <code>-I</code> option to <code>ld(1)</code>, the link-editor. The default name supplied by the link-editor is that of the runtime linker <code>ld.so.1</code>.</p> <p>During the process of executing a dynamic executable, the kernel maps the file, and locates the required interpreter. See <code>exec(2)</code> and <code>mmap(2)</code>. The kernel maps this interpreter and transfers control to it. Sufficient information is passed to the interpreter to allow it to continue binding the application and then run it.</p> <p>In addition to initializing an application, the runtime linker provides services that allow the application to extend its address space. Additional shared objects can be mapped, and symbols within these shared objects can be bound to.</p> <p>The runtime linker performs the following functions:</p> <ul style="list-style-type: none"> <li>■ It opens and processes any applicable configuration file. Configuration files may be employed to alter default search paths, provide a directory cache, and provide alternative object dependencies. See <code>crle(1)</code>. By default, the configuration file <code>/var/ld/ld.config</code> is used for 32-bit objects, and the configuration file <code>/var/ld/64/ld.config</code> for 64-bit objects. Alternative configuration files can be specified with the <code>LD_CONFIG</code> environment variable, or encoded within a dynamic executable using the <code>-c</code> option of <code>ld(1)</code>.</li> <li>■ It analyzes the application's dynamic information section (<code>.dynamic</code>) and determines which shared object dependencies are required.</li> <li>■ It locates and maps in these dependencies. It then analyzes the dynamic information section of each dependency to determine if any additional shared object dependencies are required.</li> <li>■ Once all shared object dependencies are located and mapped, the runtime linker performs any necessary relocations. These relocations bind the shared objects in preparation for process execution.</li> <li>■ It calls any initialization functions provided by the shared object dependencies and, possibly, by the dynamic executable. By default, these are called in the reverse order of the topologically sorted dependencies. If cyclic dependencies exist, the initialization functions are called using the sorted order with the cycle removed. <code>ldd(1)</code> can be used to display the initialization order of shared object</li> </ul> |

ld.so.1(1)

dependencies.

- It passes control to the application.
- During the application's execution, the runtime linker can be called upon to perform any delayed function binding.
- It calls any finalization functions on deletion of shared objects from the process. By default, these are called in the order of the topologically sorted dependencies.
- The application can also call upon the runtime linker's services to acquire additional shared objects by `dlopen(3DL)` and bind to symbols within these objects with `dlsym(3DL)`.

Further details on each of the above topics may be found in the *Linker and Libraries Guide*.

The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. The default search paths are the `runpath` recorded in the object, followed by `/usr/lib` for 32-bit objects or `/usr/lib/64` for 64-bit objects. This latter component can be modified using a configuration file created with `crle(1)`. The `runpath` is specified when the dynamic object is constructed using the `-R` option to `ld(1)`. The environment variable `LD_LIBRARY_PATH` can be used to indicate directories to be searched before the default directories.

## ENVIRONMENT VARIABLES

### LD\_AUDIT

A colon-separated list of objects that are loaded by the runtime linker. As each object is loaded, it is examined for *Link-Auditing* interface routines. The routines that are present are called as specified in the *Link-Auditing* interface described in the *Linker and Libraries Guide*. Also, see the `-p` and `-P` options of `ld(1)`.

### LD\_BIND\_NOW

The runtime linker's default mode of performing lazy binding can be overridden by setting the environment variable `LD_BIND_NOW` to any non-null value. This setting causes the runtime linker to perform both *immediate* reference and *lazy* reference relocations during process initialization, before transferring control to the application. Also, see the `-z now` option of `ld(1)`.

### LD\_CONFIG

Provides an alternative configuration file. Configuration files may be employed to alter default search paths, provide a directory cache, and provide alternate object dependencies. See `crle(1)`.

### LD\_DEBUG

Provides a comma, or colon-separated list of tokens to cause the runtime linker to print debugging information to standard error. The special token `help` indicates the full list of tokens available. The environment variable `LD_DEBUG_OUTPUT` may also be supplied to specify a file to which the debugging information is sent. The filename is suffixed with the process ID of the application generating the debugging information.

**LD\_DEMANGLE**

Any symbol name used as part of a diagnostic message is shown as it is defined within an ELF file. When **LD\_DEMANGLE** is set to any non-null value, the runtime linker attempts to decode (demangle) any C++ symbol name.

**LD\_FLAGS**

Provides an alternative means of supplying environment variable information. Any of the **LD\_XXX** environment variables can be specified as a *xxx* token. Multiple tokens can be supplied separated by commas. See **EXAMPLES**.

**LD\_LIBRARY\_PATH**

The **LD\_LIBRARY\_PATH** environment variable, if set, is used to enhance the search path that the runtime linker uses to find dynamic dependencies. **LD\_LIBRARY\_PATH** specifies a colon-separated list of directories that are searched before the default directories. Also notice that **LD\_LIBRARY\_PATH** adds additional semantics to **ld(1)**.

**LD\_LOADFLTR**

Filters are a form of shared object. They allow an alternative shared object to be selected at runtime that provide the implementation for any symbols defined within the filter. See the **-f** and **-F** options of **ld(1)**. By default, the alternative shared object processing is deferred until symbol resolution occurs against the filter. When **LD\_LOADFLTR** is set to any non-null value, any filters are processed immediately when they are loaded. Also, see the **-z loadfltr** option of **ld(1)**.

**LD\_NOAUDIT**

Local auditing libraries can be defined within applications and shared objects. See the **-p** and **-P** options of **ld(1)**. When **LD\_NOAUDIT** is set to any non-null value, the runtime linker ignores any local auditing libraries.

**LD\_NOAUXFLTR**

Auxiliary filters are a form of shared object. They allow an alternative shared object to be selected at runtime which provides the implementation for any symbols defined within the filter. See the **-f** option of **ld(1)**. When **LD\_NOAUXFLTR** is set to any non-null value, the runtime linker disables this alternative shared object lookup.

**LD\_NOCONFIG**

By default the runtime linker attempts to open and process a configuration file. When **LD\_NOCONFIG** is set to any non-null value, the runtime linker disables this configuration file processing.

**LD\_NODIRCONFIG**

Provides a subset of **LD\_NOCONFIG** in that any directory cache information provided in a configuration file is ignored.

**LD\_NODIRECT**

Direct binding information instructs the runtime linker to search directly for a symbol in an associated object. See the **-B direct** option of **ld(1)**. Without direct binding, the symbol search performed by the runtime linker follows the default model. When **LD\_NODIRECT** is set to any non-null value, the runtime linker ignores any direct binding information.

**LD\_NOENVCONFIG**

Provides a subset of **LD\_NOCONFIG** in that any environment variables provided in a configuration file are ignored.

**LD\_NOLAZYLOAD**

Dependencies labeled for lazy loading are not loaded into memory until explicit reference has been made to them. See the `-z lazyload` option of `ld(1)`. When **LD\_NOLAZYLOAD** is set to any non-null value, the runtime linker ignores a dependencies lazy loading label and loads it immediately.

**LD\_NOOBJALTER**

Provides a subset of **LD\_NOCONFIG** in that any alternative object dependencies provided in a configuration file are ignored.

**LD\_NOVERSION**

By default, the runtime linker verifies version dependencies for the primary executable and all of its dependencies. When **LD\_NOVERSION** is set to any non-null value, the runtime linker disables this version checking.

**LD\_ORIGIN**

The immediate processing of `$ORIGIN` can be triggered by setting the environment variable **LD\_ORIGIN** to any non-null value. Before Solaris 9, this option was useful for applications that invoked `chdir(2)` prior to locating dependencies that employed the `$ORIGIN` string token. The establishment of the current working directory by the runtime linker is now default thus making this option redundant.

**LD\_PRELOAD**

Provides a list of shared objects, separated by spaces. These objects are loaded after the program being executed but before any other shared objects that the program references. Symbol definitions provided by the preloaded objects interpose on references made by the shared objects that the program references. Symbol definitions provided by the preloaded objects do not interpose on the program itself.

**LD\_PROFILE**

Defines a shared object to be profiled by the runtime linker. When profiling is enabled, a profiling buffer file is created and mapped. The name of the buffer file is the name of the shared object being profiled with a `.profile` extension. By default, this buffer is placed under `/var/tmp`. The environment variable **LD\_PROFILE\_OUTPUT** may also be supplied to indicate an alternative directory in which to place the profiling buffer.

This buffer contains `profil(2)` and call count information similar to the `gmon.out` information generated by programs that have been linked with the `-xpg` option of `cc`. Any applications that use the named shared object and run while this environment variable is set, accumulate data in the profile buffer. See also **NOTES**. The profile buffer information may be examined using `gprof(1)`.

Notice that this profiling technique is an alternative to those that may be provided by the compilation system. The shared object being profiled does not have to be instrumented in any way, and `LD_PROFILE` should not be combined with a profile-instrumented application. See the *Linker and Libraries Guide* for more information on profiling shared objects.

#### LD\_SIGNAL

Provides a *numeric* signal number that the runtime linker uses to kill the process in the event of a fatal runtime error. See `thr_kill(3THR)`. By default, `SIGKILL` is used. For example, providing the alternative signal number 6 (`SIGABRT`), can provide for the creation of a core file to aid debugging. See also the `RTLD_DI_SETSIGNAL` request to `dlinfo(3DL)`.

Each environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to 32-bit or 64-bit processes. This environment variable overrides any non-suffixed version of the environment variable that may be in effect.

Notice that environment variable names beginning with the characters `'LD_'` are reserved for possible future enhancements to `ld(1)` and `ld.so.1`.

## SECURITY

Secure processes have some restrictions applied to the evaluation of their dependencies and `runpaths` to prevent malicious dependency substitution or symbol interposition.

The runtime linker categorizes a process as secure if the user is not a super-user, and the real user and effective user identifiers are not equal. Similarly, if the user is not a super-user and the real group and effective group identifiers are not equal, the process is deemed secure. See `getuid(2)`, `geteuid(2)`, `getgid(2)`, and `getegid(2)`.

The default trusted directory known to the runtime linker is `/usr/lib/secure` for 32-bit objects or `/usr/lib/secure/64` for 64-bit objects. The utility `crle(1)` may be used to specify additional trusted directories applicable for secure applications. Administrators who use this technique should ensure that the target directories are suitably protected from malicious intrusion.

If an `LD_LIBRARY_PATH` family environment variable is in effect for a secure process, only the *trusted* directories specified by this variable are used to augment the runtime linker's search rules.

In a secure process, any `runpath` specifications provided by the application or any of its dependencies is used, provided it is a full pathname, that is, the pathname starts with a `'/'`.

In a secure process, the expansion of the `$ORIGIN` string is allowed only if it expands to a *trusted* directory.

In a secure process, `LD_CONFIG` is ignored. A secure process uses the default configuration file, if it exists. See `crle(1)`.

ld.so.1(1)

In a secure process, LD\_SIGNAL is ignored.

Additional objects may be loaded with a secure process using the LD\_PRELOAD, or LD\_AUDIT environment variables. These objects must be specified as *full* pathnames or *simple* file names. Full pathnames are restricted to known *trusted* directories. Simple file names, in which no '/' appears in the name, are located subject to the search path restrictions previously described. Simple file names resolve only to known *trusted* directories.

In a secure process, any dependencies that consist of simple filenames are processed using the pathname restrictions previously described. Dependencies expressed as full or relative pathnames are used as is. Therefore, the developer of a secure process should ensure that the target directory referenced as a full or relative pathname dependency is suitably protected from malicious intrusion.

When creating a secure process, it is recommended that relative pathnames *not* be used to express dependencies or to construct dlopen(3DL) pathnames. This restriction should be applied to the application and to *all* dependencies.

#### EXAMPLES

**EXAMPLE 1** Using LD\_FLAGS to group environment variable information

The following use of LD\_FLAGS is equivalent to setting the individual environment variables LD\_BIND\_NOW and LD\_LIBRARY\_PATH for 32-bit applications:

```
example% LD_FLAGS_32=bind_now,library_path=/lib/one:/lib/two
```

The following use of LD\_FLAGS is equivalent to setting the individual environment variables LD\_LIBRARY\_PATH and LD\_PRELOAD for 64-bit applications:

```
example% LD_FLAGS_64=library_path=/lib/one/64,preload=foo.so
```

#### FILES

/usr/lib/ld.so.1  
Default runtime linker.

/etc/lib/ld.so.1  
Alternate runtime linker.

/usr/lib/libc.so.1  
Alternate interpreter for SVID ABI compatibility.

/usr/lib/ld.so  
AOUT (BCP) runtime linker.

/usr/lib/0@0.so.1  
Null character pointer compatibility library. See NOTES.

/usr/lib/secure  
LD\_PRELOAD location for secure applications.

/usr/lib/secure/64  
LD\_PRELOAD location for secure 64-bit applications.

`/usr/lib/64/ld.so.1`

Default runtime linker for 64-bit applications.

`/usr/lib/64/0@0.so.1`

Null character pointer compatibility library for the 64-bit applications.

`/var/ld/ld.config`

Default configuration file for 32-bit applications.

`/var/ld/64/ld.config`

Default configuration file for 64-bit applications.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

*Linker and Libraries Guide*

**NOTES** Care should be exercised when using `LD_PROFILE` in combination with other process monitoring techniques, such as users of `proc(4)`. Multiple process monitoring techniques can result in deadlock conditions that leave the profile buffer locked. A locked buffer blocks any processes that try to record profiling information. To reduce this likelihood, the runtime linker's profile implementation determines if the process is being monitored at startup. If so, profiling of the process is silently disabled. However, this mechanism can not catch monitoring processes that attach to the process during its execution.

The user compatibility library `/usr/lib/0@0.so.1` provides a mechanism that establishes a value of 0 at location 0. Some applications exist that erroneously assume a null character pointer should be treated the same as a pointer to a null string. A segmentation violation occurs in these applications when a null character pointer is accessed. If this library is added to such an application at runtime using `LD_PRELOAD`, it provides an environment that is sympathetic to this errant behavior. However, the user compatibility library is intended neither to enable the generation of such applications, nor to endorse this particular programming practice.

let(1)

**NAME** | let – shell built-in function to evaluate one or more arithmetic expressions

**ksh** | **let** *arg...*

**ksh** | Each *arg* is a separate "arithmetic expression" to be evaluated.

**EXIT STATUS** | The following exit values are returned:

0 | The value of the last expression is non-zero.

1 | The value of the last expression is zero.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `ksh(1)`, `set(1)`, `typeset(1)`, `attributes(5)`

| <b>NAME</b>        | lex – generate programs for lexical tasks                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <b>lex</b> [-cntv] [-e   -w] [-V -Q [y   n]] [ <i>file</i> ...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | The <code>lex</code> utility generates C programs to be used in lexical processing of character input, and that can be used as an interface to <code>yacc</code> . The C programs are generated from <code>lex</code> source code and conform to the ISO C standard. Usually, the <code>lex</code> utility writes the program it generates to the file <code>lex.yy.c</code> . The state of this file is unspecified if <code>lex</code> exits with a non-zero exit status. See <b>EXTENDED DESCRIPTION</b> for a complete description of the <code>lex</code> input language.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li>-c                Indicates C-language action (default option).</li> <li>-e                Generates a program that can handle EUC characters (cannot be used with the <code>-w</code> option). <code>yytext [ ]</code> is of type <code>unsigned char [ ]</code>.</li> <li>-n                Suppresses the summary of statistics usually written with the <code>-v</code> option. If no table sizes are specified in the <code>lex</code> source code and the <code>-v</code> option is not specified, then <code>-n</code> is implied.</li> <li>-t                Writes the resulting program to standard output instead of <code>lex.yy.c</code>.</li> <li>-v                Writes a summary of <code>lex</code> statistics to the standard error. (See the discussion of <code>lex</code> table sizes under the heading <i>Definitions</i> in <code>lex</code>.) If table sizes are specified in the <code>lex</code> source code, and if the <code>-n</code> option is not specified, the <code>-v</code> option may be enabled.</li> <li>-w                Generates a program that can handle EUC characters (cannot be used with the <code>-e</code> option). Unlike the <code>-e</code> option, <code>yytext [ ]</code> is of type <code>wchar_t [ ]</code>.</li> <li>-V                Prints out version information on standard error.</li> <li>-Q[y n]          Prints out version information to output file <code>lex.yy.c</code> by using <code>-Qy</code>. The <code>-Qn</code> option does not print out version information and is the default.</li> </ul> |
| <b>OPERANDS</b>    | The following operand is supported: <ul style="list-style-type: none"> <li><i>file</i>            A pathname of an input file. If more than one such <i>file</i> is specified, all files will be concatenated to produce a single <code>lex</code> program. If no <i>file</i> operands are specified, or if a <i>file</i> operand is <code>-</code>, the standard input will be used.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OUTPUT</b>      | The <code>lex</code> output files are described below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Stdout</b>      | If the <code>-t</code> option is specified, the text file of C source code output of <code>lex</code> will be written to standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

lex(1)

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

These statistics may also be generated if table sizes are specified with a <code>%</code> operator in the <code>Definitions in lex</code> section (see <code>EXTENDED DESCRIPTION</code>), as long as the <code>-n</code> option is not specified.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <p><b>Output Files</b></p>         | <p>A text file containing C source code will be written to <code>lex.yy.c</code>, or to the standard output if the <code>-t</code> option is present.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <p><b>EXTENDED DESCRIPTION</b></p> | <p>Each input file contains <code>lex</code> source code, which is a table of regular expressions with corresponding actions in the form of C program fragments.</p> <p>When <code>lex.yy.c</code> is compiled and linked with the <code>lex</code> library (using the <code>-l lex</code> operand with <code>c89</code> or <code>cc</code>), the resulting program reads character input from the standard input and partitions it into strings that match the given expressions.</p> <p>When an expression is matched, these actions will occur:</p> <ul style="list-style-type: none"><li>■ The input string that was matched is left in <code>ytext</code> as a null-terminated string; <code>ytext</code> is either an external character array or a pointer to a character string. As explained in <code>Definitions in lex</code>, the type can be explicitly selected using the <code>%array</code> or <code>%pointer</code> declarations, but the default is <code>%array</code>.</li><li>■ The external <code>int yyleng</code> is set to the length of the matching string.</li><li>■ The expression's corresponding program fragment, or action, is executed.</li></ul> <p>During pattern matching, <code>lex</code> searches the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first will be chosen.</p> <p>The general format of <code>lex</code> source is:</p> <pre>Definitions %% Rules %% User Subroutines</pre> <p>The first <code>%%</code> is required to mark the beginning of the rules (regular expressions and actions); the second <code>%%</code> is required only if user subroutines follow.</p> |

Any line in the `Definitions in lex` section beginning with a blank character will be assumed to be a C program fragment and will be copied to the external definition area of the `lex.yy.c` file. Similarly, anything in the `Definitions in lex` section included between delimiter lines containing only `%{` and `%}` will also be copied unchanged to the external definition area of the `lex.yy.c` file.

Any such input (beginning with a blank character or within `%{` and `%}` delimiter lines) appearing at the beginning of the `Rules` section before any rules are specified will be written to `lex.yy.c` after the declarations of variables for the `yylex` function and before the first line of code in `yylex`. Thus, user variables local to `yylex` can be declared here, as well as application code to execute upon entry to `yylex`.

The action taken by `lex` when encountering any input beginning with a blank character or within `%{` and `%}` delimiter lines appearing in the `Rules` section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the `yylex` function.

## Definitions in lex

`Definitions in lex` appear before the first `%%` delimiter. Any line in this section not contained between `%{` and `%}` lines and not beginning with a blank character is assumed to define a `lex` substitution string. The format of these lines is:

```
name substitute
```

If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string *substitute* will replace the string `{ name }` when it is used in a rule. The *name* string is recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the `Definitions in lex` section, any line beginning with a `%` (percent sign) character and followed by an alphanumeric word beginning with either `s` or `S` defines a set of start conditions. Any line beginning with a `%` followed by a word beginning with either `x` or `X` defines a set of exclusive start conditions. When the generated scanner is in a `%s` state, patterns with no state specified will be also active; in a `%x` state, such patterns will not be active. The rest of the line, after the first word, is considered to be one or more blank-character-separated names of start conditions. Start condition names are constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular expressions to one or more states as described in `Regular expressions in lex`.

Implementations accept either of the following two mutually exclusive declarations in the `Definitions in lex` section:

```
%array Declare the type of ytext to be a null-terminated character array.
%pointer Declare the type of ytext to be a pointer to a null-terminated
 character string.
```

*Note:* When using the `%pointer` option, you may not also use the `yyles` function to alter *ytext*.

lex(1)

%array is the default. If %array is specified (or neither %array nor %pointer is specified), then the correct way to make an external reference to *yytext* is with a declaration of the form:

```
extern char yytext []
```

If %pointer is specified, then the correct external reference is of the form:

```
extern char *yytext;
```

lex will accept declarations in the Definitions in lex section for setting certain internal table sizes. The declarations are shown in the following table.

Table Size Declaration in lex

| Declaration | Description                        | Default |
|-------------|------------------------------------|---------|
| %pn         | Number of positions                | 2500    |
| %nn         | Number of states                   | 500     |
| %an         | Number of transitions              | 2000    |
| %en         | Number of parse tree nodes         | 1000    |
| %kn         | Number of packed character classes | 10000   |
| %on         | Size of the output array           | 3000    |

Programs generated by lex need either the -e or -w option to handle input that contains EUC characters from supplementary codesets. If neither of these options is specified, *yytext* is of the type `char [ ]`, and the generated program can handle only ASCII characters.

When the -e option is used, *yytext* is of the type `unsigned char [ ]` and *yylen* gives the total number of *bytes* in the matched string. With this option, the macros `input ( )`, `unput (c)`, and `output (c)` should do a byte-based I/O in the same way as with the regular ASCII lex. Two more variables are available with the -e option, *yywtext* and *yywlen*, which behave the same as *yytext* and *yylen* would under the -w option.

When the -w option is used, *yytext* is of the type `wchar_t [ ]` and *yylen* gives the total number of *characters* in the matched string. If you supply your own `input ( )`, `unput (c)`, or `output (c)` macros with this option, they must return or accept EUC characters in the form of wide character (`wchar_t`). This allows a different interface between your program and the lex internals, to expedite some programs.

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Rules in lex</b>               | <p>The Rules in lex source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.</p> <pre>ERE action ERE action ...</pre> <p>The extended regular expression (ERE) portion of a row will be separated from <i>action</i> by one or more blank characters. A regular expression containing blank characters is recognized under one of the following conditions:</p> <ul style="list-style-type: none"> <li>■ The entire expression appears within double-quotes.</li> <li>■ The blank characters appear within double-quotes or square brackets.</li> <li>■ Each blank character is preceded by a backslash character.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>User Subroutines in lex</b>    | <p>Anything in the user subroutines section will be copied to <code>lex.yy.c</code> following <code>yylex</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Regular Expressions in lex</b> | <p>The lex utility supports the set of Extended Regular Expressions (EREs) described on <code>regex(5)</code> with the following additions and exceptions to the syntax:</p> <pre>. . .</pre> <p>Any string enclosed in double-quotes will represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) are recognized. Any backslash-escape sequence is terminated by the closing quote. For example, "<code>\ 01</code>" represents a single string: the octal value 1 followed by the character 1.</p> <pre>&lt;state&gt;r &lt;state1, state2, ...&gt;r</pre> <p>The regular expression <i>r</i> will be matched only when the program is in one of the start conditions indicated by <i>state</i>, <i>state1</i>, and so forth. For more information, see <i>Actions in lex</i>. As an exception to the typographical conventions of the rest of this document, in this case <code>&lt;state&gt;</code> does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol. The start condition is recognized as such only at the beginning of a regular expression.</p> <pre>r/x</pre> <p>The regular expression <i>r</i> will be matched only if it is followed by an occurrence of regular expression <i>x</i>. The token returned in <i>yytext</i> will only match <i>r</i>. If the trailing portion of <i>r</i> matches the beginning of <i>x</i>, the result is unspecified. The <i>r</i> expression cannot include further trailing context or the <code>\$</code> (match-end-of-line) operator; <i>x</i> cannot include the <code>^</code> (match-beginning-of-line) operator, nor trailing context, nor the <code>\$</code> operator. That is, only one occurrence of trailing context is allowed in a lex regular expression, and the <code>^</code> operator only can be used at the beginning of such an expression. A further restriction is that the trailing-context operator <code>/</code> (slash) cannot be grouped within parentheses.</p> |

lex(1)

{*name*}

When *name* is one of the substitution symbols from the *Definitions* section, the string, including the enclosing braces, will be replaced by the *substitute* value. The *substitute* value will be treated in the extended regular expression as if it were enclosed in parentheses. No substitution will occur if {*name*} occurs within a bracket expression or within double-quotes.

Within an ERE, a backslash character ( \, \ a, \ b, \ f, \ n, \ r, \ t, \ v) is considered to begin an escape sequence. In addition, the escape sequences in the following table will be recognized.

A literal newline character cannot occur within an ERE; the escape sequence \ n can be used to represent a newline character. A newline character cannot be matched by a period operator.

Escape Sequences in lex

| Escape Sequences in lex |                                                                                                                                                                                                                       |                                                                                                                                                                                                                        |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Escape Sequence         | Description                                                                                                                                                                                                           | Meaning                                                                                                                                                                                                                |
| <i>\digits</i>          | A backslash character followed by the longest sequence of one, two or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined. | The character whose encoding is represented by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading \ for each byte. |
| <i>\xdigits</i>         | A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined. | The character whose encoding is represented by the hexadecimal integer.                                                                                                                                                |
| <i>\c</i>               | A backslash character followed by any character not described in this table. (\, \a, \b, \f, \n, \r, \t, \v).                                                                                                         | The character <i>c</i> , unchanged.                                                                                                                                                                                    |

The order of precedence given to extended regular expressions for lex is as shown in the following table, from high to low.

*Note:* The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true

operators. The start condition, trailing context and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

| ERE Precedence in lex                    |                         |
|------------------------------------------|-------------------------|
| <i>collation-related bracket symbols</i> | [ = = ] [ : : ] [ . . ] |
| <i>escaped characters</i>                | \<special character>    |
| <i>bracket expression</i>                | [ ]                     |
| <i>quoting</i>                           | ". . ."                 |
| <i>grouping</i>                          | ()                      |
| <i>definition</i>                        | { name }                |
| <i>single-character RE duplication</i>   | * + ?                   |
| <i>concatenation</i>                     |                         |
| <i>interval expression</i>               | { m,n }                 |
| <i>alternation</i>                       |                         |

The ERE anchoring operators ( `^` and `$` ) do not appear in the table. With `lex` regular expressions, these operators are restricted in their use: the `^` operator can only be used at the beginning of an entire regular expression, and the `$` operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern `(^abc) | (def$)` is undefined; it can instead be written as two separate rules, one with the regular expression `^abc` and one with `def$`, which share a common action via the special `|` action (see below). If the pattern were written `^abc|def$`, it would match either of `abc` or `def` on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical `lex` implementations. An example of embedded anchoring would be for patterns such as `(^)foo($)` to match `foo` when it exists as a complete word. This functionality can be obtained using existing `lex` features:

```
^foo/[\ n] |
"foo"/[\ n] /* found foo as a separate word */
```

Notice also that `$` is a form of trailing context (it is equivalent to `/[ \ n]` and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

lex(1)

The additional regular expressions trailing-context operator / (slash) can be used as an ordinary character if presented within double-quotes, " / "; preceded by a backslash, \ /; or within a bracket expression, [ / ]. The start-condition < and > operators are special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they are treated as ordinary characters.

The following examples clarify the differences between lex regular expressions and regular expressions appearing elsewhere in this document. For regular expressions of the form *r/x*, the string matching *r* is always returned; confusion may arise when the beginning of *x* matches the trailing portion of *r*. For example, given the regular expression *a\*b/cc* and the input *aaabcc*, *yytext* would contain the string *aaab* on this match. But given the regular expression *x\*/xy* and the input *xxxxy*, the token *xxx*, not *xx*, is returned by some implementations because *xxx* matches *x\**.

In the rule *ab\*/bc*, the *b\** at the end of *r* will extend *r*'s match into the beginning of the trailing context, so the result is unspecified. If this rule were *ab/bc*, however, the rule matches the text *ab* when it is followed by the text *bc*. In this latter case, the matching of *r* cannot extend into the beginning of *x*, so the result is specified.

#### Actions in lex

The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement `;` is a valid action; any string in the `lex.yy.c` input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action is not valid, and the action lex takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
program statement }
```

The default action when a string in the input to a `lex.yy.c` program is not matched by any expression is to copy the string to the output. Because the default behavior of a program generated by lex is to read the input and copy it to the output, a minimal lex source program that has just `%%` generates a C program that simply copies the input to the output unchanged.

Four special actions are available:

| ECHO; REJECT; BEGIN

| The action | means that the action for the next rule is the action for this rule. Unlike the other three actions, | cannot be enclosed in braces or be semicolon-terminated. It must be specified alone, with no other actions.

ECHO; Writes the contents of the string *yytext* on the output.

REJECT; Usually only a single expression is matched by a given string in the input. REJECT means "continue to the next expression that

matches the current input," and causes whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions `xyz` and `xy` and the input `xyz`, usually only the regular expression `xyz` would match. The next attempted match would start after `z`. If the last action in the `xyz` rule is `REJECT`, both this rule and the `xy` rule would be executed. The `REJECT` action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a `goto` to another part of `yylex`. The use of `REJECT` may result in somewhat larger and slower scanners.

`BEGIN`

The action:

```
BEGIN newstate ;
```

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the `Definitions` in `lex` section, the results are unspecified. The initial state is indicated by the digit `0` or the token `INITIAL`.

The functions or macros described below are accessible to user code included in the `lex` input. It is unspecified whether they appear in the C code output of `lex`, or are accessible only through the `-l l` operand to `c89` or `cc` (the `lex` library).

|                                |                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>int yylex(void)</code>   | Performs lexical analysis on the input; this is the primary function generated by the <code>lex</code> utility. The function returns zero when the end of input is reached; otherwise it returns non-zero values (tokens) determined by the actions that are selected.                                                                                                         |
| <code>int yymore(void)</code>  | When called, indicates that when the next input string is recognized, it is to be appended to the current value of <i>ytext</i> rather than replacing it; the value in <i>yylen</i> is adjusted accordingly.                                                                                                                                                                   |
| <code>int yyless(int n)</code> | Retains <i>n</i> initial characters in <i>ytext</i> , NUL-terminated, and treats the remaining characters as if they had not been read; the value in <i>yylen</i> is adjusted accordingly.                                                                                                                                                                                     |
| <code>int input(void)</code>   | Returns the next character from the input, or zero on end-of-file. It obtains input from the stream pointer <i>yyin</i> , although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of <i>yyin</i> is undefined. The character read is removed from the input stream of the scanner without any processing by the scanner. |

lex(1)

`int unput (int c)` Returns the character *c* to the input; *yytext* and *yylen* are undefined until the next expression is matched. The result of using *unput* for more characters than have been input is unspecified.

The following functions appear only in the `lex` library accessible through the `-l lex` operand; they can therefore be redefined by a portable application:

`int yywrap (void)`

Called by `yylex` at end-of-file; the default `yywrap` always will return 1. If the application requires `yylex` to continue processing with another source of input, then the application can include a function `yywrap`, which associates another file with the external variable `FILE *yyin` and will return a value of zero.

`int main (int argc, char *argv [ ])`

Calls `yylex` to perform lexical analysis, then exits. The user code can contain `main` to perform application-specific operations, calling `yylex` as applicable.

The reason for breaking these functions into two lists is that only those functions in `libl.a` can be reliably redefined by a portable application.

Except for `input`, `unput` and `main`, all external and static names generated by `lex` begin with the prefix `yy` or `YY`.

**USAGE** Portable applications are warned that in the `Rules in lex` section, an ERE without an action is not acceptable, but need not be detected as erroneous by `lex`. This may result in compilation or run-time errors.

The purpose of `input` is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The `lex` utility is not fully internationalized in its treatment of regular expressions in the `lex` source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the `lex` source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current `lex` technology. Furthermore, the very nature of the lexical analyzers produced by `lex` must be closely tied to the lexical requirements of the input language being described, which will frequently be locale-specific anyway. (For example, writing an analyzer that is used for French text will not automatically be useful for processing other languages.)

**EXAMPLES** **EXAMPLE 1** Using `lex`

The following is an example of a `lex` program that implements a rudimentary scanner for a Pascal-like syntax:

```
%{
/* need this for the call to atof() below */
#include <math.h>
/* need this for printf(), fopen() and stdin below */
#include <stdio.h>
```

**EXAMPLE 1** Using lex *(Continued)*

```

%}

DIGIT [0-9]
ID [a-z][a-z0-9]*
%%

{DIGIT}+ {
 printf("An integer: %s (%d)\n", yytext,
 atoi(yytext));
 }

{DIGIT}+"."{DIGIT}* {
 printf("A float: %s (%g)\n", yytext,
 atof(yytext));
 }

if|then|begin|end|procedure|function {
 printf("A keyword: %s\n", yytext);
 }

{ID} printf("An identifier: %s\n", yytext);

"+"|"-"|"*"|"\/" printf("An operator: %s\n", yytext);

"{" [^}\n]*}" /* eat up one-line comments */

[\t\n]+ /* eat up white space */

. printf("Unrecognized character: %s\n", yytext);

%%

int main(int argc, char *argv[])
{
 ++argv, --argc; /* skip over program name */
 if (argc > 0)
 yyin = fopen(argv[0], "r");
 else
 yyin = stdin;

 yylex();
}

```

**ENVIRONMENT  
VARIABLES**

See environ(5) for descriptions of the following environment variables that affect the execution of lex: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following exit values are returned:

```

0 Successful completion.
>0 An error occurred.

```

lex(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWbtool       |
| Interface Stability | Standard        |

**SEE ALSO** `yacc(1)`, `attributes(5)`, `environ(5)`, `regex(5)`, `standards(5)`

**NOTES** If routines such as `yyback()`, `yywrap()`, and `yylock()` in `.1` (ell) files are to be external C functions, the command line to compile a C++ program must define the `__EXTERN_C__` macro. For example:

```
example% CC -D__EXTERN_C__ ... file
```

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>            | limit, ulimit, unlimited – set or get limitations on the system resources available to the current shell and its descendants                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>        | <code>/usr/bin/ulimit [-f] [blocks]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>/usr/bin/ulimit</b> | The <code>ulimit</code> utility sets or reports the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>sh</b>              | The Bourne shell built-in function, <code>ulimit</code> , prints or sets hard or soft resource limits. These limits are described in <code>getrlimit(2)</code> .<br><br>If <i>limit</i> is not present, <code>ulimit</code> prints the specified limits. Any number of limits may be printed at one time. The <code>-a</code> option prints all limits.<br><br>If <i>limit</i> is present, <code>ulimit</code> sets the specified limit to <i>limit</i> . The string <code>unlimited</code> requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see <code>su(1M)</code> .<br><br>The <code>-H</code> option specifies a hard limit. The <code>-S</code> option specifies a soft limit. If neither option is specified, <code>ulimit</code> will set both limits and print the soft limit.<br><br>The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set. |

|                        | <code>-n</code> maximum file descriptor plus 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                        | <code>-s</code> maximum size of stack segment (in kbytes)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                        | <code>-t</code> maximum CPU time (in seconds)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                        | <code>-v</code> maximum size of virtual memory (in kbytes)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## limit(1)

- cs**h | The C-shell built-in function, `limit`, limits the consumption by the current process or any process it spawns, each not to exceed *limit* on the specified *resource*. If *limit* is omitted, print the current limit; if *resource* is omitted, display all limits. (Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` command).
- h            Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.
- resource* is one of:
- |                           |                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------|
| <code>cputime</code>      | Maximum CPU seconds per process.                                                               |
| <code>filesize</code>     | Largest single file allowed. Limited to the size of the filesystem (see <code>df(1M)</code> ). |
| <code>datasize</code>     | The maximum size of a process's heap in kilobytes.                                             |
| <code>stacksize</code>    | Maximum stack size for the process (see <code>swap(1M)</code> ).                               |
| <code>coredumpsize</code> | Maximum size of a core dump (file). This is limited to the size of the filesystem.             |
| <code>descriptors</code>  | Maximum number of file descriptors (run <code>sysdef( )</code> ).                              |
| <code>memorysize</code>   | Maximum size of virtual memory.                                                                |
- limit* is a number, with an optional scaling factor, as follows:
- |                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <code>nh</code>    | Hours (for <code>cputime</code> ).                                         |
| <code>nk</code>    | <i>n</i> kilobytes. This is the default for all but <code>cputime</code> . |
| <code>nm</code>    | <i>n</i> megabytes or minutes (for <code>cputime</code> ).                 |
| <code>mm:ss</code> | Minutes and seconds (for <code>cputime</code> ).                           |
- `unlimit` removes a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the `limit` command for the list of resource names.
- h            Remove corresponding hard limits. Only the privileged user may do this.
- ks**h | The Korn shell built-in function, `ulimit`, sets or displays a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value `unlimited`. The `-H` and `-S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the `-H` or `-S` options is

specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case, the soft limit is printed unless `-H` is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- `-a` Lists all of the current resource limits.
- `-c` The number of 512-byte blocks on the size of core dumps.
- `-d` The number of K-bytes on the size of the data area.
- `-f` The number of 512-byte blocks on files written by child processes (files of any size may be read).
- `-n` The number of file descriptors plus 1.
- `-s` The number of K-bytes on the size of the stack area.
- `-t` The number of seconds (CPU time) to be used by each process.
- `-v` The number of K-bytes for virtual memory.

If no option is given, `-f` is assumed.

**OPTIONS** The following option is supported by `ulimit`:

- `-f` Set (or report, if no *blocks* operand is present), the file size limit in blocks. The `-f` option is also the default case.

**OPERANDS** The following operand is supported by `ulimit`:

*blocks* The number of 512-byte blocks to use as the new file size limit.

`/usr/bin/ulimit` **EXAMPLE 1** Limiting the stack size

To limit the stack size to 512 kilobytes:

```
example% ulimit -s 512
example% ulimit -a
time(seconds) unlimited
file(blocks) 100
data(kbytes) 523256
stack(kbytes) 512
coredump(blocks) 200
nofiles(descriptors) 64
memory(kbytes) unlimited
```

`sh/ksh` **EXAMPLE 2** Limiting the number of file descriptors

To limit the number of file descriptors to 12:

```
example$ ulimit -n 12
example$ ulimit -a
time(seconds) unlimited
file(blocks) 41943
data(kbytes) 523256
stack(kbytes) 8192
```

## limit(1)

### EXAMPLE 2 Limiting the number of file descriptors *(Continued)*

```
coredump(blocks) 200
nofiles(descriptors) 12
vmemory(kbytes) unlimited
```

### csH EXAMPLE 3 Limiting the core dump file size

To limit the size of a core dump file size to 0 kilobytes:

```
example% limit coredumpsize 0
example% limit
cputime unlimited
filesize unlimited
datasize 523256 kbytes
stacksize 8192 kbytes
coredumpsize 0 kbytes
descriptors 64
memorysize unlimited
```

### EXAMPLE 4 Removing the limitation for core file size

To remove the above limitation for the core file size:

```
example% unlimit coredumpsize
example% limit
cputime unlimited
filesize unlimited
datasize 523256 kbytes
stacksize 8192 kbytes
coredumpsize unlimited
descriptors 64
memorysize unlimited
```

### ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `ulimit`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

### EXIT STATUS

The following exit values are returned by `ulimit`:

0           Successful completion.

>0          A request for a higher limit was rejected or an error occurred.

### ATTRIBUTES

line(1)

**NAME** | line – read one line

**SYNOPSIS** | **line**

**DESCRIPTION** | The `line` utility copies one line (up to and including a new-line) from the standard input and writes it on the standard output. It returns an exit status of 1 on EOF and always prints at least a new-line. It is often used within shell files to read from the user's terminal.

**EXIT STATUS** | Exit status is:

0            Successful completion

>0          End-of-file on input.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `sh(1)`, `read(2)`, `attributes(5)`

| <b>SYNOPSIS</b>    | <code>/usr/ucb/lint</code> [ <i>options</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <code>/usr/ucb/lint</code> is the interface to the BSD Compatibility Package C program verifier. It is a script that looks for the link <code>/usr/ccs/bin/ucblint</code> to the C program verifier. <code>/usr/ccs/bin/ucblint</code> is available only with the SPROcc package, whose default location is <code>/opt/SUNWspro</code> . <code>/usr/ucb/lint</code> is identical to <code>/usr/ccs/bin/ucblint</code> , except that BSD headers are used and BSD libraries are linked <i>before</i> base libraries. The <code>/opt/SUNWspro/man/man1/lint.1</code> man page is available only with the SPROcc package.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p><code>/usr/ucb/lint</code> accepts the same options as <code>/usr/ccs/bin/ucblint</code>, with the following exceptions:</p> <ul style="list-style-type: none"> <li>-I<i>dir</i>            Search <i>dir</i> for included files whose names do not begin with a slash ( / ) prior to searching the usual directories. The directories for multiple -I options are searched in the order specified. The preprocessor first searches for #include files in the directory containing <i>sourcefile</i>, and then in directories named with -I options (if any), then <code>/usr/ucbinclude</code>, and finally, in <code>/usr/include</code>.</li> <li>-L<i>dir</i>            Add <i>dir</i> to the list of directories searched for libraries by <code>/usr/ccs/bin/ucblint</code>. This option is passed to <code>/usr/ccs/bin/ld</code>. Directories specified with this option are searched before <code>/usr/ucb/lib</code> and <code>/usr/lib</code>.</li> <li>-Y <i>P, dir</i>        Change the default directory used for finding libraries.</li> </ul> |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0                Successful completion.</li> <li>&gt;0              An error occurred.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | list_devices – list allocatable devices                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <pre>list_devices [-s] [-U uid] -l [device] list_devices [-s] [-U uid] -n [device] list_devices [-s] [-U uid] -u [device]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The <code>list_devices</code> utility lists the allocatable devices in the system according to specified qualifications.</p> <p>The <i>device</i> and all device special files associated with the device are listed. The device argument is optional and, if it is not present, all relevant devices are listed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-l [<i>device</i>]        Lists the pathname(s) of the device special files associated with the device that are allocatable to the current process. If <i>device</i> is given, lists only the files associated with the specified device.</li> <li>-n [<i>device</i>]        Lists the pathname(s) of device special files associated with the device that are allocatable to the current process but are not currently allocated. If <i>device</i> is given, lists only the files associated with that device.</li> <li>-s                    Silent. Suppresses any diagnostic output.</li> <li>-u [<i>device</i>]        Lists the pathname(s) of device special files, associated with the device that are allocated to the owner of the current process. If <i>device</i> is given, list only the files associated with that device.</li> <li>-U <i>uid</i>             Uses the user ID <i>uid</i> instead of the real user ID of the current process when performing the <code>list_devices</code> operation. Only a user with the <code>solaris.devices.revoke</code> authorization can use this option.</li> </ul> |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>non—zero        An error occurred.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**NOTES** The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

- NAME** listusers – list user login information
- SYNOPSIS** **listusers** [-g *groups*] [-l *logins*]
- DESCRIPTION** Executed without any options, this command lists all user logins sorted by login. The output shows the login ID and the account field value from the system's password database as specified by `/etc/nsswitch.conf`.
- OPTIONS** The following options are supported:
- g *groups* Lists all user logins belonging to *group*, sorted by login. Multiple groups can be specified as a comma-separated list.
  - l *logins* Lists the user login or logins specified by *logins*, sorted by login. Multiple logins can be specified as a comma-separated list.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:
- | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
- SEE ALSO** `nsswitch.conf(4)`, `attributes(5)`
- NOTES** A user login is one that has a UID of 100 or greater.
- The -l and -g options can be combined. User logins will only be listed once, even if they belong to more than one of the selected groups.

## llc2\_autoconfig(1)

| <b>NAME</b>        | llc2_autoconfig – generate LLC2 configuration files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/lib/llc2/llc2_autoconfig [-f]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The llc2_autoconfig utility is used to generate LLC2 configuration files (<code>/etc/llc2/default/llc2.*</code>). If there is no configuration file in <code>/etc/llc2_default/</code>, it detects all the available interfaces in the system and generates corresponding default configuration files.</p> <p>If there are existing configuration files in <code>/etc/llc2_default/</code>, it will check if those interfaces defined in the files still exist. If they do not exist in the system, it will set <code>llc2_on</code> in those files to 0. After this, it will detect if there are new interfaces in the system. If there are, it will generate configuration files for them.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following option is supported:</p> <p><code>-f</code> Erases all configuration files in <code>/etc/llc2/default/</code>. Then detects all the available interfaces in the system and generates corresponding default configuration files. Use this option with caution.</p>                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>FILES</b>       | <code>/etc/llc2/default/llc2.*</code> LLC2 configuration files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/lib/llc2/llc2_config [-P   -U   -d   -q   -i <i>ppa</i>   -r <i>ppa</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |      |              |          |         |        |        |        |      |   |    |      |              |          |      |   |   |
| <b>DESCRIPTION</b> | The <code>llc2_config</code> utility is used to start/stop the LLC2 subsystem and to configure LLC2 interface parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |              |          |         |        |        |        |      |   |    |      |              |          |      |   |   |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-d</code> Turns on debug mode. Extra debugging information will be printed out.</li> <li><code>-i <i>ppa</i></code> Initializes the corresponding interface using the file <code>/etc/llc2/default/llc2.<i>ppa</i></code>.</li> <li><code>-P</code> Reads in all <code>/etc/llc2/default/llc2.*</code> configuration files, opens those devices defined in the files, and sets up the streams needed for LLC2 to use those devices. Before doing this, <code>llc2_config -q</code> will not show anything.</li> <li><code>-q</code> Queries the LLC2 subsystem. Information similar to the following example will be printed out for all PPAs (Physical Point of Attachment) available under the LLC2 module:</li> </ul> <table style="margin-left: 40px;"> <thead> <tr> <th>PPA</th> <th>State</th> <th>ID</th> <th>MACAddr</th> <th>Type</th> <th>MaxSDU</th> <th>MinSDU</th> <th>Mode</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>up</td> <td>0000</td> <td>0800208a217e</td> <td>ethernet</td> <td>1500</td> <td>0</td> <td>3</td> </tr> </tbody> </table> <p>The fields displayed are described below:</p> <ul style="list-style-type: none"> <li>PPA The relative logical position of the interface.</li> <li>State The state of the interface: <ul style="list-style-type: none"> <li><i>up</i> The interface is initialized and operational.</li> <li><i>down</i> The interface was "discovered" by the LLC2 driver, has passed its bootup diagnostics, and is awaiting initialization.</li> <li><i>bad</i> The interface is known to the LLC2 driver, but failed one or more of the integrity checks performed at boot time. This might include detecting Interrupt Request and shared memory conflicts or failures detected during the execution of the level 0 diagnostics.</li> </ul> </li> <li>ID The interface ID.</li> <li>MACAddr The MAC address currently in effect for the interface.</li> <li>Type The MAC type. ## llc2\_config(1)

csma/cd 10 Megabit Ethernet  
ethernet Ethernet type device  
tkn-ring 4/16 Megabit Token Ring  
fddi 100 Megabit Fiber Distributed Data Interface

MaxSDU The Maximum Service Data Unit size transmitted on this interface.

Mode The Service Modes supported by this interface. This field consists of the bitwise logical-ORing of the supported modes, also defined in `/usr/include/sys/dlpi.h`.

`-r ppa` Uninitializes the corresponding interface. By using this option, and then using the `-i` option, the parameters associated with an interface can be changed.

`-U` Destroys all streams used by the LLC2 subsystem. This is the reverse of the `-P` option. After this is executed, `llc2_config -q` will not show anything.

**FILES** `/etc/llc2/default/llc2.*` LLC2 configuration files

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWllc         |

| <b>SYNOPSIS</b>    | <b>llc2_stats</b> <i>ppa</i> [-r] [-s <i>sap</i> ] [-c <i>connection</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | The llc2_stats command is used to retrieve statistical information from the Host-based Logical Link Control Class 2 component of the LLC2 Driver. Statistics are kept for the station, SAP (Service Access Point), and connection components.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-c <i>connection</i>                      Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.</p> <p>-r                                        Resets the specified counters to zero after reading them. This option is only valid if the <i>root</i> user is executing the command.</p> <p>-s <i>sap</i>                                 Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS sap, 240 (0xf0) would be entered as: -s f0.</p>                                                                                                                                                                                                                                                                                                                                              |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><i>ppa</i>                                      The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Station Statistics</p> <p>The following command will display the station statistics for PPA 4. After the example, a brief description of each field is presented.</p> <pre>example% /usr/lib/llc2/llc2_stats 4</pre> <pre>Station values received: ppa                = 0x00000004  clearFlag = 0x00 # of saps (hex)    = 0x0002 saps (hex)        = 02 aa state             = 0x01 nullSapXidCmdRcvd = 0x00000000 nullSapXidRspSent = 0x00000000 nullSapTestCmdRcvd = 0x00000000 nullSapTestRspSent = 0x00000000 outOfState        = 0x00000000 allocFail         = 0x00000000 protocolError     = 0x00000000</pre> <p>The fields are described as follows:</p> <p><i>ppa</i>                                      The logical number used to address the adapter.</p> <p><i>clearFlag</i>                              This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).</p> |

## llc2\_stats(1)

### EXAMPLE 1 Station Statistics (Continued)

|                    |                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| # of saps          | The number of SAPs currently bound on this station.                                                                            |
| saps               | The array of the station's Service Access Point (SAP) logical interface values between the LLC and its adjacent layers.        |
| state              | A number indicating the current state of the station component (0 = down, 1 = up).                                             |
| nullSapXidCmdRcvd  | The number of XID command Protocol Data Units (PDUs) received for the NULL SAP address (sap = 0x00).                           |
| nullSapXidRspSent  | The number of XID response PDUs sent in response to XID command PDUs received for the null SAP address.                        |
| nullSapTestCmdRcvd | The number of TEST command PDUs received for the null SAP address.                                                             |
| nullSapTestRspSent | The number of TEST response PDUs sent in response to TEST command PDUs received for the null SAP address.                      |
| outOfState         | The number of events received in an invalid state.                                                                             |
| allocFail          | The number of buffer allocation failures.                                                                                      |
| protocolError      | The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected. |

### EXAMPLE 2 SAP Statistics

In the above display, there are two active SAPs, 0x02 and 0xaa. The following is an example of a command for retrieving the statistics for SAP 02 and a brief explanation of each field presented.

```
example% /usr/lib/llc2/llc2_stats 4 -s 02
```

```
Sap values received:
ppa = 0x00000004 clearFlag = 0x00
sap = 0x02
state = 0x01
of cons (hex) = 0x0000000a
connections (hex) = 0000 0001 0002 0003 0004 0005 0006 0007 0008 0009
xidCmdSent = 0x00000000
xidCmdRcvd = 0x00000000
xidRspSent = 0x00000000
xidRspRcvd = 0x00000000
testCmdSent = 0x00000000
testCmdRcvd = 0x00000000
testRspSent = 0x00000000
```

**EXAMPLE 2** SAP Statistics (Continued)

```

testRspRcvd = 0x00000000
uiSent = 0x00000000
uiRcvd = 0x00000000
outOfState = 0x00000000
allocFail = 0x00000000
protocolError = 0x00000000

```

The fields are described as follows:

|             |                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------|
| ppa         | The logical number used to address the adapter.                                                                                       |
| clearFlag   | This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0). |
| sap         | The specified Service Access Point (SAP) logical interface value for the station.                                                     |
| state       | A number indicating the current state of the SAP component (0 = inactive, 1 = active).                                                |
| # of cons   | The number of active connections on this SAP.                                                                                         |
| connections | The array of active connection indexes.                                                                                               |
| xidCmdSent  | The number of XID command PDUs sent (Source SAP = this sap).                                                                          |
| xidCmdRcvd  | The number of XID command PDUs received (Destination SAP = this sap).                                                                 |
| xidRspSent  | The number of XID response PDUs sent (Source SAP = this sap).                                                                         |
| xidRspRcvd  | The number of XID response PDUs received (Source SAP = this sap).                                                                     |
| testCmdSent | The number of TEST command PDUs sent (Source SAP = this sap).                                                                         |
| testCmdRcvd | The number of TEST command PDUs received (Destination SAP = this sap).                                                                |
| testRspSent | The number of TEST response PDUs sent (Source SAP = this sap).                                                                        |
| testRspRcvd | The number of TEST response PDUs received (Source SAP = this sap).                                                                    |
| uiSent      | The number of Unnumbered Information Frames sent.                                                                                     |
| uiRcvd      | The number of Unnumbered Information Frames received.                                                                                 |

## llc2\_stats(1)

### EXAMPLE 2 SAP Statistics (Continued)

|               |                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| outOfState    | The number of events received in an invalid state.                                                                             |
| allocFail     | The number of buffer allocation failures.                                                                                      |
| protocolError | The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected. |

### EXAMPLE 3 Connection Statistics

Ten established connections are associated with this SAP. To retrieve the statistics for connection 1, enter the following command:

```
example% /usr/lib/llc2/llc2_stats 4 -s 2 -c 1
Connection values received:
ppa = 0x0004 clearFlag = 0x00

|-------------|---------------------------------------------------------------------------------------------------------------------------------------|
| ppa         | The logical number used to address the adapter.                                                                                       |
| clearFlag   | This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0). |
| sap         | The specified Service Access Point (SAP) logical interface value for the station.                                                     |
| con         | The specified connection index value for the SAP.                                                                                     |
| stateOldest | A number representing the state of the connection component prior to stateOlder.                                                      |

**EXAMPLE 3** Connection Statistics (Continued)

|              |                                                                                                                                                                    |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stateOlder   | A number representing the state of the connection component prior to stateOld.                                                                                     |
| stateOld     | A number representing the state of the connection component prior to state.                                                                                        |
| state        | A number representing the most current state of the connection component. See Table 1.                                                                             |
| sid          | The Station Identifier composed of the SAP (upper byte) and connection index (lower byte).                                                                         |
| dl_nodeaddr  | The Data Link Node Address. This is the destination node's MAC address.                                                                                            |
| dl_sap       | The destination node's SAP.                                                                                                                                        |
| flag         | The connection component processing flag. See Table 3.                                                                                                             |
| dataFlag     | A number representing the status of the data units from received I-frame PDUs (0 = not discarded, 1 = discarded, 2 = busy state entered with REJ PDU outstanding). |
| timerOn      | A number representing the timer activity flag, with each bit representing an active timer for this connection. See Table 2 for timer definitions.                  |
| vs           | The sequence number of the next I-frame PDU to send.                                                                                                               |
| vr           | The expected sequence number of the next I-frame PDU to be received.                                                                                               |
| nrRcvd       | The sequence number plus 1 of the last sent I-frame PDU acknowledged by the remote node.                                                                           |
| k            | The transmit window size.                                                                                                                                          |
| retryCount   | The retryCount is incremented whenever a timer expiration occurs. These timers protect outbound frames.                                                            |
| numToBeAcked | The number of outbound I-frames awaiting acknowledgement.                                                                                                          |
| numToResend  | The number of outbound I-frames to be retransmitted.                                                                                                               |
| macOutSave   | No longer used.                                                                                                                                                    |
| macOutDump   | No longer used.                                                                                                                                                    |
| iSent        | The number of I-frames sent.                                                                                                                                       |

## llc2\_stats(1)

### EXAMPLE 3 Connection Statistics (Continued)

|               |                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| iRcvd         | The number of I-frames received.                                                                                               |
| frmrSent      | The number of Frame Reject PDUs (FRMR) sent.                                                                                   |
| frmrRcvd      | The number of Frame Reject PDUs (FRMR) received.                                                                               |
| rrSent        | The number of Receiver Ready PDUs (RR) sent.                                                                                   |
| rrRcvd        | The number of Receiver Ready PDUs (RR) received.                                                                               |
| rnrSent       | The number of Receiver Not Ready PDUs (RNR) sent.                                                                              |
| rnrRcvd       | The number of Receiver Not Ready PDUs (RNR) received.                                                                          |
| rejSent       | The number of Reject PDUs (REJ) sent.                                                                                          |
| rejRcvd       | The number of Reject PDUs (REJ) received.                                                                                      |
| sabmeSent     | The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) sent.                                                       |
| sabmeRcvd     | The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) received.                                                   |
| uaSent        | The number of Unnumbered Acknowledgment PDUs (UA) sent.                                                                        |
| uaRcvd        | The number of Unnumbered Acknowledgment PDUs (UA) received.                                                                    |
| discSent      | The number of Disconnect PDUs (DISC) sent.                                                                                     |
| outOfState    | The number of events received in an invalid state.                                                                             |
| allocFail     | The number of buffer allocation failures.                                                                                      |
| protocolError | The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected. |
| localBusy     | The number of times this component was in local busy state and could not accept I-frames.                                      |
| remoteBusy    | The number of times the remote connection component was busy and could not accept I-frames.                                    |
| maxRetryFail  | The number of failures that occurred because maxRetry was reached.                                                             |
| ackTimerExp   | The number of expirations of the Acknowledgement timer.                                                                        |
| pollTimerExp  | The number of expirations of the Poll timer.                                                                                   |

**EXAMPLE 3** Connection Statistics (Continued)

|                 |                                                              |
|-----------------|--------------------------------------------------------------|
| rejTimerExp     | The number of expirations of the Reject timer.               |
| remBusyTimerExp | The number of expirations of the Remote Busy timer.          |
| inactTimerExp   | The number of expirations of the Inactivity timer.           |
| sendAckTimerExp | The number of expirations of the Send Acknowledgement timer. |

**Table 1: LLC2 States**

|                |      |
|----------------|------|
| STATION        |      |
| ~~DOWN         | 0x00 |
| ~~UP           | 0x01 |
| SAP            |      |
| ~~INACTIVE     | 0x00 |
| ~~ACTIVE       | 0x01 |
| CONNECTION     |      |
| ~~ADM          | 0x00 |
| ~~CONN         | 0x01 |
| ~~RESET_WAIT   | 0x02 |
| ~~RESET_CHECK  | 0x03 |
| ~~SETUP        | 0x04 |
| ~~RESET        | 0x05 |
| ~~D_CONN       | 0x06 |
| ~~ERROR        | 0x07 |
| ~~NORMAL       | 0x08 |
| ~~BUSY         | 0x09 |
| ~~REJECT       | 0x0a |
| ~~AWAIT        | 0x0b |
| ~~AWAIT_BUSY   | 0x0c |
| ~~AWAIT_REJECT | 0x0d |

## llc2\_stats(1)

|                      |      |
|----------------------|------|
| Acknowledgement      | 0x80 |
| Poll                 | 0x40 |
| Reject               | 0x20 |
| Remove Busy          | 0x10 |
| Inactivity           | 0x08 |
| Send Acknowledgement | 0x04 |

| <b>DESCRIPTION</b> | <p>In the first synopsis form, the <code>ln</code> utility creates a new directory entry (link) for the file specified by <i>source_file</i>, at the destination path specified by <i>target</i>. If <i>target</i> is not specified, the link is made in the current directory. This first synopsis form is assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error will result.</p> <p>In the second synopsis form, the <code>ln</code> utility creates a new directory entry for each file specified by a <i>source_file</i> operand, at a destination path in the existing directory named by <i>target</i>.</p> <p>The <code>ln</code> utility may be used to create both hard links and symbolic links. A hard link is a pointer to a file and is indistinguishable from the original directory entry. Any changes to a file are effective independent of the name used to reference the file. Hard links may not span file systems and may not refer to directories.</p> <p><code>ln</code> by default creates hard links. <i>source_file</i> is linked to <i>target</i>. If <i>target</i> is a directory, another file named <i>source_file</i> is created in <i>target</i> and linked to the original <i>source_file</i>.</p> <p><b>/usr/bin/ln</b> If <i>target</i> is a file, its contents are overwritten. If <code>/usr/bin/ln</code> determines that the mode of <i>target</i> forbids writing, it will print the mode (see <code>chmod(1)</code>), ask for a response, and read the standard input for one line. If the response is affirmative, the link occurs, if permissible. Otherwise, the command exits.</p> <p><b>/usr/xpg4/bin/ln</b> If <i>target</i> is a file and the <code>-f</code> option is not specified, <code>/usr/xpg4/bin/ln</code> will write a diagnostic message to standard error, do nothing more with the current <i>source_file</i>, and go on to any remaining <i>source_files</i>.</p> <p>A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span file systems and may refer to directories.</p> <p>When creating a hard link, and the source file is itself a symbolic link, then the target will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself (<i>source_file</i>).</p> <p>File permissions for <i>target</i> may be different from those displayed with a <code>-l</code> listing of the <code>ls(1)</code> command. To display the permissions of <i>target</i> use <code>ls -lL</code>. See <code>stat(2)</code> for more information.</p> |
| <b>OPTIONS</b>     | The following options are supported for both <code>/usr/bin/ln</code> and <code>/usr/xpg4/bin/ln</code> :                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

ln(1)

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <p>-f      Link files without questioning the user, even if the mode of <i>target</i> forbids writing. This is the default if the standard input is not a terminal.</p> <p>-s      Create a symbolic link.</p> <p>If the -s option is used with two arguments, <i>target</i> may be an existing directory or a non-existent file. If <i>target</i> already exists and is not a directory, an error is returned. <i>source_file</i> may be any path name and need not exist. If it exists, it may be a file or directory and may reside on a different file system from <i>target</i>. If <i>target</i> is an existing directory, a file is created in directory <i>target</i> whose name is <i>source_file</i> or the last component of <i>source_file</i>. This file is a symbolic link that references <i>source_file</i>. If <i>target</i> does not exist, a file with name <i>target</i> is created and it is a symbolic link that references <i>source_file</i>.</p> <p>If the -s option is used with more than two arguments, <i>target</i> must be an existing directory or an error will be returned. For each <i>source_file</i>, a link is created in <i>target</i> whose name is the last component of <i>source_file</i>. Each new <i>source_file</i> is a symbolic link to the original <i>source_file</i>. The files and <i>target</i> may reside on different file systems.</p> |
| <b>/usr/bin/ln</b>           | <p>The following options are supported for /usr/bin/ln only:</p> <p>-n      If the link is an existing file, do not overwrite the contents of the file. The -f option overrides this option. This is the default behavior for /usr/xpg4/bin/ln, and is silently ignored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPERANDS</b>              | <p>The following operands are supported:</p> <p><i>source_file</i>      A path name of a file to be linked. This can be either a regular or special file. If the -s option is specified, <i>source_file</i> can also be a directory.</p> <p><i>target</i>            The path name of the new directory entry to be created, or of an existing directory in which the new directory entries are to be created.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>USAGE</b>                 | <p>See <code>largefile(5)</code> for the description of the behavior of <code>ln</code> when encountering files greater than or equal to 2 Gbyte ( <math>2^{31}</math> bytes).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**NOTES**

A symbolic link to a directory behaves differently than you might expect in certain cases. While an `ls(1)` on such a link displays the files in the pointed-to directory, an `'ls -l'` displays information about the link itself:

```
example% ln -s dir link
example% ls link
file1 file2 file3 file4
example% ls -l link
lrwxrwxrwx 1 user 7 Jan 11 23:27 link -> dir
```

When you `cd(1)` to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is `/usr` and not `/home/user/linktest`.

```
example% pwd
/home/user/linktest
example% ln -s /usr/tmp symlink
example% cd symlink
example% cd . .
example% pwd
/usr
```

C shell users can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

ln(1B)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>        | ln – make hard or symbolic links to files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>/usr/ucb/ln [-fs] filename [linkname] /usr/ucb/ln [-fs] pathname... directory</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>The <code>/usr/ucb/ln</code> utility creates an additional directory entry, called a link, to a file or directory. Any number of links can be assigned to a file. The number of links does not affect other file attributes such as size, protections, data, etc.</p> <p><i>filename</i> is the name of the original file or directory. <i>linkname</i> is the new name to associate with the file or filename. If <i>linkname</i> is omitted, the last component of <i>filename</i> is used as the name of the link.</p> <p>If the last argument is the name of a directory, symbolic links are made in that directory for each <i>pathname</i> argument; <code>/usr/ucb/ln</code> uses the last component of each <i>pathname</i> as the name of each link in the named <i>directory</i>.</p> <p>A hard link (the default) is a standard directory entry just like the one made when the file was created. Hard links can only be made to existing files. Hard links cannot be made across file systems (disk partitions, mounted file systems). To remove a file, all hard links to it must be removed, including the name by which it was first created; removing the last hard link releases the inode associated with the file.</p> <p>A symbolic link, made with the <code>-s</code> option, is a special directory entry that points to another named file. Symbolic links can span file systems and point to directories. In fact, you can create a symbolic link that points to a file that is currently absent from the file system; removing the file that it points to does not affect or alter the symbolic link itself.</p> <p>A symbolic link to a directory behaves differently than you might expect in certain cases. While an <code>ls(1)</code> on such a link displays the files in the pointed-to directory, an <code>'ls -l'</code> displays information about the link itself:</p> <pre>example% /usr/ucb/ln -s dir link example% ls link file1 file2 file3 file4 example% ls -l link lrwxrwxrwx  1 user          7 Jan 11 23:27 link -&gt; dir</pre> <p>When you use <code>cd(1)</code> to change to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is <code>/usr</code> and not <code>/home/user/linktest</code>.</p> <pre>example% pwd /home/user/linktest example% /usr/ucb/ln -s /var/tmp symlink example% cd symlink example% cd . .</pre> |

```
example% pwd
/usr
```

C shell users can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

**OPTIONS**

- `-f` Force a hard link to a directory. This option is only available to the super-user, and should be used with extreme caution.
- `-s` Create a symbolic link or links.

**USAGE** See `largefile(5)` for the description of the behavior of `ln` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** The `/usr/ucb/ln` command

The commands below illustrate the effects of the different forms of the `/usr/ucb/ln` command:

```
example% /usr/ucb/ln file link
example% ls -F file link
file link
example% /usr/ucb/ln -s file symlink
example% ls -F file symlink
file symlink@
example% ls -li file link symlink
 10606 -rw-r--r-- 2 user 0 Jan 12 00:06 file
 10606 -rw-r--r-- 2 user 0 Jan 12 00:06 link
 10607 lrwxrwxrwx 1 user 4 Jan 12 00:06 symlink -> file
example% /usr/ucb/ln -s nonesuch devoid
example% ls -F devoid
devoid@
example% cat devoid
devoid: No such file or directory
example% /usr/ucb/ln -s /proto/bin/* /tmp/bin
example% ls -F /proto/bin /tmp/bin
/proto/bin:
x* y* z*

/tmp/bin:
x@ y@ z@
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO** `cp(1)`, `ls(1)`, `mv(1)`, `rm(1)`, `link(2)`, `readlink(2)`, `stat(2)`, `symlink(2)`, `attributes(5)`, `largefile(5)`

ln(1B)

**NOTES** | When the last argument is a directory, simple basenames should not be used for *pathname* arguments. If a basename is used, the resulting symbolic link points to itself:

```
example% /usr/ucb/ln -s file /tmp
example% ls -l /tmp/file
lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file -> file
example% cat /tmp/file
/tmp/file: Too many levels of symbolic links
```

To avoid this problem, use full pathnames, or prepend a reference to the PWD variable to files in the working directory:

```
example% rm /tmp/file
example% /usr/ucb/ln -s $PWD/file /tmp
lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file ->
/home/user/subdir/file
```

| <b>NAME</b>         | loadkeys, dumpkeys – load and dump keyboard translation tables                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |                     |          |

| <b>DESCRIPTION</b>  | <p>loadkeys reads the file specified by <i>filename</i>, and modifies the keyboard streams module's translation tables. If no file is specified, loadkeys loads the file: <code>/usr/share/lib/keytables/type_</code><i>tt</i><code>/layout_</code><i>dd</i>, where <i>tt</i> is the value returned by the <code>KIOCTYPE</code> <code>ioctl</code>, and <i>dd</i> is the value returned by the <code>KIOCLAYOUT</code> <code>ioctl</code> (see <code>kb(7M)</code>). These keytable files specify only the entries that change between the specified layout and the default layout for the particular keyboard type. On self-identifying keyboards, the value returned by the <code>KIOCLAYOUT</code> <code>ioctl</code> is set from the DIP switches.</p> <p>dumpkeys writes the current contents of the keyboard streams module's translation tables, in the format specified by <code>keytables(4)</code>, to the standard output.</p> |                |                 |              |         |                     |          |
| <b>FILES</b>        | <code>/usr/share/lib/keytables/layout_</code> <i>dd</i><br>default keytable files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |                     |          |
| <b>ATTRIBUTES</b>   | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |         |                     |          |
|                     | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWcsu | Interface Stability | Evolving |

| <b>DESCRIPTION</b> | <p>The <code>locale</code> utility writes information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a <i>public locale</i> is one provided by the implementation that is accessible to the application.</p> <p>When <code>locale</code> is invoked without any arguments, it summarizes the current locale environment for each locale category as determined by the settings of the environment variables.</p> <p>When invoked with operands, it writes values that have been assigned to the keywords in the locale categories, as follows:</p> <ul style="list-style-type: none"><li>■ Specifying a keyword name selects the named keyword and the category containing that keyword.</li><li>■ Specifying a category name selects the named category and all keywords in that category.</li></ul> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-a Writes information about all available public locales. The available locales include <code>POSIX</code>, representing the POSIX locale.</li><li>-c Writes the names of selected locale categories. The <code>-c</code> option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the <code>-k</code> option.</li><li>-k Writes the names and values of selected keywords. The implementation may omit values for some keywords; see <code>OPERANDS</code>.</li><li>-m Writes names of available charmaps; see <code>localedef(1)</code>.</li></ul>                                                                                                                    |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><i>name</i> The name of a locale category, the name of a keyword in a locale category, or the reserved name <code>charmap</code>. The named category or keyword will be selected for output. If a single <i>name</i> represents both a locale category name and a keyword name in the current locale, the results are unspecified; otherwise, both category and keyword names can be specified as <i>name</i> operands, in any sequence.</p>                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples of the locale utility</p> <p>In the following examples, the assumption is that locale environment variables are set as follows:</p> <pre>LANG=locale_x LC_COLLATE=locale_y</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**EXAMPLE 1** Examples of the locale utility (Continued)

The command `locale` would result in the following output:

```
LANG=locale_x
LC_CTYPE="locale_x"
LC_NUMERIC="locale_x"
LC_TIME="locale_x"
LC_COLLATE=locale_y
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=
```

The command

```
LC_ALL=POSIX locale -ck decimal_point
```

would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of `locale` to determine whether a user-supplied response is affirmative:

```
if printf "%s\n" "$response" | /usr/xpg4/bin/grep -Eq\
 "$(locale yesexpr)"
then
 affirmative processing goes here
else
 non-affirmative processing goes here
fi
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for the descriptions of `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The `LANG`, `LC_*`, and `NLSPATH` environment variables must specify the current locale environment to be written out. These environment variables will be used if the `-a` option is not specified.

**EXIT STATUS**

The following exit values are returned:

- 0 All the requested information was found and output successfully.
- >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |

locale(1)

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| CSI                 | Enabled         |
| Interface Stability | Standard        |

**SEE ALSO** localedef(1), attributes(5), charmap(5), environ(5), locale(5), standards(5)

**NOTES** If LC\_CTYPE or keywords in the category LC\_CTYPE are specified, only the values in the range 0x00-0x7f are written out.

If LC\_COLLATE or keywords in the category LC\_COLLATE are specified, no actual values are written out.

| <b>DESCRIPTION</b>         | <p>The <code>localedef</code> utility converts source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables; see <code>environ(5)</code>.</p> <p>The utility reads source definitions for one or more locale categories belonging to the same locale from the file named in the <code>-i</code> option (if specified) or from standard input.</p> <p>Each category source definition is identified by the corresponding environment variable name and terminated by an <code>END <i>category-name</i></code> statement. The following categories are supported.</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">LC_CTYPE</td> <td>Defines character classification and case conversion.</td> </tr> <tr> <td>LC_COLLATE</td> <td>Defines collation rules.</td> </tr> <tr> <td>LC_MONETARY</td> <td>Defines the format and symbols used in formatting of monetary information.</td> </tr> <tr> <td>LC_NUMERIC</td> <td>Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.</td> </tr> <tr> <td>LC_TIME</td> <td>Defines the format and content of date and time information.</td> </tr> <tr> <td>LC_MESSAGES</td> <td>Defines the format and values of affirmative and negative responses.</td> </tr> </table> | LC_CTYPE | Defines character classification and case conversion.               | LC_COLLATE                 | Defines collation rules.                                                                                                                                                                                                                                    | LC_MONETARY       | Defines the format and symbols used in formatting of monetary information.                                                                                                                                                                                                                                                                                                           | LC_NUMERIC | Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing. | LC_TIME | Defines the format and content of date and time information. | LC_MESSAGES | Defines the format and values of affirmative and negative responses. |
| LC_CTYPE                   | Defines character classification and case conversion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |          |                                                                     |                            |                                                                                                                                                                                                                                                             |                   |                                                                                                                                                                                                                                                                                                                                                                                      |            |                                                                                               |         |                                                              |             |                                                                      |

|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>-i sourcefile</i>      | The path name of a file containing the source definitions. If this option is not present, source definitions will be read from standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>-L linker_options</i>  | Passes the <i>linker_options</i> to the C compiler (cc) that follows the C source filename. If more than one option is specified, then the options must be enclosed in quotes (" ").                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>-m model</i>           | <p>This is an old option. Use the <i>-W cc,arg</i> option instead.</p> <p>Specifies whether <code>localedef</code> will generate a 64-bit or a 32-bit locale object.</p> <p>Specify <i>model</i> as <code>ilp32</code> to generate a 32-bit locale object. Specify <code>lp64</code> to generate a 64-bit locale object. If the <i>-m</i> option is not specified, <code>localedef</code> generates a 32-bit locale object. And if no other options than <i>-c</i>, <i>-f</i>, and <i>-i</i> options are specified and if the system running <code>localedef</code> supports the 64-bit environment, <code>localedef</code> additionally generates a 64-bit locale object.</p> |
| <i>-W cc,arg</i>          | <p>Passes <i>arg</i> options to the C compiler. Each argument must be separated from the preceding by only a comma. (A comma can be part of an argument by escaping it by an immediately preceding backslash character; the backslash is removed from the resulting argument.)</p> <p>Use this option instead of the <i>-C</i> and <i>-L</i> options.</p>                                                                                                                                                                                                                                                                                                                      |
| <i>-x extensions_file</i> | Specifies the name of an extension file where various <code>localedef</code> options are listed. See <code>locale(5)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPERANDS</b>           | <p>The following operand is supported:</p> <p><i>localename</i> Identifies the locale. If the name contains one or more slash characters, <i>localename</i> will be interpreted as a path name where the created locale definitions will be stored. This capability may be restricted to users with appropriate privileges. (As a consequence of specifying one <i>localename</i>, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)</p>                                                                                                                                                          |
| <b>OUTPUT</b>             | <p><code>localedef</code> creates a temporary C source file that represents the locale's data. <code>localedef</code> then calls the C compiler to compile this C source file into a shared object.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

If the `-m ilp32` option is specified, `localedef` calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If the `-m lp64` option is specified, `localedef` calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If the `-m` option is not specified, `localedef` calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If no other options than `-c`, `-f`, and `-i` options are specified and if the system running `localedef` supports the 64-bit environment, `localedef` additionally calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If no option to the C compiler is explicitly specified using the `-W`, `-C`, or `-L` options, `localedef` calls the C compiler with appropriate C compiler options to generate a locale object or objects.

If the `-m ilp32` option is specified, `localedef` generates a 32-bit locale object named:

*localename.so.version\_number*

If the `-m lp64` option is specified, `localedef` generates a 64-bit locale object named:

*localename.so.version\_number*

If the `-m` option is not specified, `localedef` generates a 32-bit locale object named:

*localename.so.version\_number*

and, if appropriate, generates a 64-bit locale object named:

*64-bit\_architecture\_name/localename.so.version\_number*

The shared object for the 32-bit environment must be moved to:

*/usr/lib/locale/localename/localename.so.version\_number*

The shared object for the 64-bit environment on SPARC must be moved to:

*/usr/lib/locale/localename/sparcv9/localename.so.version\_number*

`localedef` also generates a text file named *localename* that is used for information only.

**ENVIRONMENT VARIABLES**

See `environ(5)` for definitions of the following environment variables that affect the execution of `localedef`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 No errors occurred and the locales were successfully created.
- 1 Warnings occurred and the locales were successfully created.

## localedef(1)

- 2 The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.
- 3 The capability to create new locales is not supported by the implementation.
- >3 Warnings or errors occurred and no output was created.

If an error is detected, no permanent output will be created.

### FILES

`/usr/lib/localedef/extensions/generic_eucbc.x`  
Describes what a generic EUC locale uses in the system. This file is used by default.

`/usr/lib/localedef/extensions/single_byte.x`  
Describes a generic single-byte file used in the system.

`/usr/lib/locale/localename/localename.so.version_number`  
The shared object for the 32-bit environment.

`/usr/lib/locale/localename/sparcv9/localename.so.version_number`  
The shared object for the 64-bit environment on SPARC.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

### SEE ALSO

`locale(1)`, `nl_langinfo(3C)`, `strftime(3C)`, `attributes(5)`, `charmap(5)`, `environ(5)`, `extensions(5)`, `locale(5)`, `standards(5)`

### WARNINGS

If warnings occur, permanent output will be created if the `-c` option was specified. The following conditions will cause warning messages to be issued:

- If a symbolic name not found in the `charmap` file is used for the descriptions of the `LC_CTYPE` or `LC_COLLATE` categories (for other categories, this will be an error conditions).
- If optional keywords not supported by the implementation are present in the source.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>                  | logger – add entries to the system log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>              | <b>logger</b> [-i] [-f <i>file</i> ] [-p <i>priority</i> ] [-t <i>tag</i> ] [ <i>message</i> ] ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b>           | The <code>logger</code> command provides a method for adding one-line entries to the system log file from the command line. One or more <i>message</i> arguments can be given on the command line, in which case each is logged immediately. If this is unspecified, either the file indicated with <code>-f</code> or the standard input is added to the log. Otherwise, a <i>file</i> can be specified, in which case each line in the file is logged. If neither is specified, <code>logger</code> reads and logs messages on a line-by-line basis from the standard input.                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>               | The following options are supported: <ul style="list-style-type: none"> <li><code>-f<i>file</i></code>            Uses the contents of <i>file</i> as the message to log.</li> <li><code>-i</code>                    Logs the process ID of the <code>logger</code> process with each line.</li> <li><code>-p<i>priority</i></code>        Enters the message with the specified <i>priority</i>. The message priority can be specified numerically, or as a <i>facility.level</i> pair. For example, <code>'-p local3.info'</code> assigns the message priority to the <code>info</code> level in the <code>local3</code> facility. The default priority is <code>user.notice</code>.</li> <li><code>-t<i>tag</i></code>              Marks each line added to the log with the specified <i>tag</i>.</li> </ul> |
| <b>OPERANDS</b>              | The following operand is supported: <ul style="list-style-type: none"> <li><i>message</i>            One of the string arguments whose contents are concatenated together, in the order specified, separated by single space characters.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EXAMPLES</b>              | <b>EXAMPLE 1</b> Examples of the <code>logger</code> command<br>The following example:<br><pre>example% logger System rebooted</pre> logs the message 'System rebooted' to the default priority level <code>notice</code> to be treated by <code>syslogd</code> as are other messages to the facility <code>user</code> .<br>The next example:<br><pre>example% logger -p local0.notice -t HOSTIDM -f /dev/idmc</pre> reads from the file <code>/dev/idmc</code> and logs each line in that file as a message with the tag 'HOSTIDM' at priority level <code>notice</code> to be treated by <code>syslogd</code> as are other messages to the facility <code>local0</code> .                                                                                                                                       |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>logger</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EXIT STATUS</b>           | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | logger – add entries to the system log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/logger [-f <i>filename</i>] [-i] [-p <i>priority</i>] [-t <i>tag</i>] mm [<i>message</i>]...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | The logger utility provides a method for adding one-line entries to the system log file from the command line. One or more <i>message</i> arguments can be given on the command line, in which case each is logged immediately. If <i>message</i> is unspecified, either the file indicated with <code>-f</code> or the standard input is added to the log. Otherwise, a <i>filename</i> can be specified, in which case each line in the file is logged. If neither is specified, logger reads and logs messages on a line-by-line basis from the standard input.                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li><code>-i</code>                      Log the process ID of the logger process with each line.</li> <li><code>-f <i>filename</i></code>            Use the contents of <i>filename</i> as the message to log.</li> <li><code>-p <i>priority</i></code>            Enter the message with the specified <i>priority</i>. The message priority can be specified numerically, or as a <i>facility.level</i> pair. For example, <code>'-p local3.info'</code> assigns the message priority to the <i>info</i> level in the <i>local3</i> facility. The default priority is <i>user.notice</i>.</li> <li><code>-t <i>tag</i></code>                 Mark each line added to the log with the specified <i>tag</i>.</li> </ul> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Logging a message</p> <p>The command:</p> <pre>example% logger System rebooted</pre> <p>will log the message 'System rebooted' to the facility at priority notice to be treated by syslogd as other messages to the facility notice are.</p> <p><b>EXAMPLE 2</b> Logging messages from a file</p> <p>The command:</p> <pre>example% logger -p local0.notice -t HOSTIDM -f /dev/idmc</pre> <p>will read from the file <code>/dev/idmc</code> and will log each line in that file as a message with the tag 'HOSTIDM' at priority notice to be treated by syslogd as other messages to the facility local0 are.</p>                                                                                                                                                               |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>        | login – sign on to the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>login</b> [-p] [-d <i>device</i> ] [-h <i>hostname</i>   [ <i>terminal</i> ]   -r <i>hostname</i> ] [ <i>name</i> [ <i>environ</i> ] ...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>The <code>login</code> command is used at the beginning of each terminal session to identify oneself to the system. <code>login</code> is invoked by the system when a connection is first established, after the previous user has terminated the login shell by issuing the <code>exit</code> command.</p> <p>If <code>login</code> is invoked as a command, it must replace the initial command interpreter. To invoke <code>login</code> in this fashion, type:</p> <pre>exec login</pre> <p>from the initial shell. The C shell and Korn shell have their own builtins of <code>login</code>. See <code>ksh(1)</code> and <code>cksh(1)</code> for descriptions of <code>login</code> builtins and usage.</p> <p><code>login</code> asks for your user name, if it is not supplied as an argument, and your password, if appropriate. Where possible, echoing is turned off while you type your password, so it will not appear on the written record of the session.</p> <p>If you make any mistake in the login procedure, the message:</p> <pre>Login incorrect</pre> <p>is printed and a new login prompt will appear. If you make five incorrect login attempts, all five may be logged in <code>/var/adm/loginlog</code>, if it exists. The TTY line will be dropped.</p> <p>If password aging is turned on and the password has "aged" (see <code>passwd(1)</code> for more information), the user is forced to change the password. In this case the <code>/etc/nsswitch.conf</code> file is consulted to determine password repositories (see <code>nsswitch.conf(4)</code>). The password update configurations supported are limited to the following five cases.</p> <ul style="list-style-type: none"> <li>■ <code>passwd: files</code></li> <li>■ <code>passwd: files nis</code></li> <li>■ <code>passwd: files nisplus</code></li> <li>■ <code>passwd: compat (==&gt; files nis)</code></li> <li>■ <code>passwd: compat (==&gt; files nisplus)</code></li> </ul> <pre>passwd_compat: nisplus</pre> <p>Failure to comply with the configurations will prevent the user from logging onto the system because <code>passwd(1)</code> will fail. If you do not complete the login successfully within a certain period of time, it is likely that you will be silently disconnected.</p> <p>After a successful login, accounting files are updated. Device owner, group, and permissions are set according to the contents of the <code>/etc/logindevperm</code> file, and the time you last logged in is printed (see <code>logindevperm(4)</code>).</p> |

## login(1)

The user-ID, group-ID, supplementary group list, and working directory are initialized, and the command interpreter (usually `ksh`) is started.

The basic *environment* is initialized to:

```
HOME=your-login-directory
LOGNAME=your-login-name
PATH=/usr/bin:
SHELL=last-field-of-passwd-entry
MAIL=/var/mail/
TZ=timezone-specification
```

For Bourne shell and Korn shell logins, the shell executes `/etc/profile` and `$HOME/.profile`, if it exists. For C shell logins, the shell executes `/etc/.login`, `$HOME/.cshrc`, and `$HOME/.login`. The default `/etc/profile` and `/etc/.login` files check quotas (see `quota(1M)`), print `/etc/motd`, and check for mail. None of the messages are printed if the file `$HOME/.hushlogin` exists. The name of the command interpreter is set to `-` (dash), followed by the last component of the interpreter's path name, for example, `-sh`.

If the *login-shell* field in the password file (see `passwd(4)`) is empty, then the default command interpreter, `/usr/bin/sh`, is used. If this field is `*` (asterisk), then the named directory becomes the root directory. At that point, `login` is re-executed at the new level, which must have its own root structure.

The environment may be expanded or modified by supplying additional arguments to `login`, either at execution time or when `login` requests your login name. The arguments may take either the form `xxx` or `xxx=yyy`. Arguments without an `=` (equal sign) are placed in the environment as:

```
Ln=xxx
```

where *n* is a number starting at 0 and is incremented each time a new variable name is required. Variables containing an `=` (equal sign) are placed in the environment without modification. If they already appear in the environment, then they replace the older values.

There are two exceptions: The variables `PATH` and `SHELL` cannot be changed. This prevents people logged into restricted shell environments from spawning secondary shells that are not restricted. `login` understands simple single-character quoting conventions. Typing a `\` (backslash) in front of a character quotes it and allows the inclusion of such characters as spaces and tabs.

Alternatively, you can pass the current environment by supplying the `-p` flag to `login`. This flag indicates that all currently defined environment variables should be passed, if possible, to the new environment. This option does not bypass any environment variable restrictions mentioned above. Environment variables specified on the login line take precedence, if a variable is passed by both methods.

To enable remote logins by root, edit the `/etc/default/login` file by inserting a # (pound sign) before the `CONSOLE=/dev/console` entry. See FILES.

**SECURITY**

The `login` command uses pam(3PAM) for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `login`. Here is a partial `pam.conf` file with entries for the `login` command using the UNIX authentication, account management, and session management modules:

```
login auth required pam_authtok_get.so.1
login auth required pam_dhkeys.so.1
login auth required pam_unix_auth.so.1
login auth required pam_dial_auth.so.1

login account requisite pam_roles.so.1
login account required pam_projects.so.1
login account required pam_unix_account.so.1

login session required pam_unix_session.so.1
```

The Password Management stack looks like the following:

```
other password required pam_dhkeys.so.1
other password requisite pam_authtok_get.so.1
other password requisite pam_authtok_check.so.1
other password required pam_authtok_store.so.1
```

If there are no entries for the service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

When `login` is invoked through `rlogind` or `telnetd`, the service name used by PAM is `rlogin` or `telnet`, respectively.

**OPTIONS**

The following options are supported:

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-d device</code>                | <code>login</code> accepts a device option, <i>device</i> . <i>device</i> is taken to be the path name of the TTY port <code>login</code> is to operate on. The use of the device option can be expected to improve <code>login</code> performance, since <code>login</code> will not need to call <code>ttynname(3C)</code> . The <code>-d</code> option is available only to users whose UID and effective UID are root. Any other attempt to use <code>-d</code> will cause <code>login</code> to quietly exit. |
| <code>-h hostname [ terminal ]</code> | Used by <code>in.telnetd(1M)</code> to pass information about the remote host and terminal type.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-p</code>                       | Used to pass environment variables to the <code>login</code> shell.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## login(1)

|                    |                                         |                                                                                                                        |
|--------------------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------|
|                    | <code>-r hostname</code>                | Used by <code>in.rlogind(1M)</code> to pass information about the remote host.                                         |
| <b>EXIT STATUS</b> | The following exit values are returned: |                                                                                                                        |
|                    | 0                                       | Successful operation.                                                                                                  |
|                    | non-zero                                | Error.                                                                                                                 |
| <b>FILES</b>       | <code>\$HOME/.cshrc</code>              | initial commands for each csh                                                                                          |
|                    | <code>\$HOME/.hushlogin</code>          | suppresses login messages                                                                                              |
|                    | <code>\$HOME/.login</code>              | user's login commands for csh                                                                                          |
|                    | <code>\$HOME/.profile</code>            | user's login commands for sh and ksh                                                                                   |
|                    | <code>\$HOME/.rhosts</code>             | private list of trusted hostname/username combinations                                                                 |
|                    | <code>/etc/.login</code>                | system-wide csh login commands                                                                                         |
|                    | <code>/etc/issue</code>                 | issue or project identification                                                                                        |
|                    | <code>/etc/logindevperm</code>          | login-based device permissions                                                                                         |
|                    | <code>/etc/motd</code>                  | message-of-the-day                                                                                                     |
|                    | <code>/etc/nologin</code>               | message displayed to users attempting to login during machine shutdown                                                 |
|                    | <code>/etc/passwd</code>                | password file                                                                                                          |
|                    | <code>/etc/profile</code>               | system-wide sh and ksh login commands                                                                                  |
|                    | <code>/etc/shadow</code>                | list of users' encrypted passwords                                                                                     |
|                    | <code>/usr/bin/sh</code>                | user's default command interpreter                                                                                     |
|                    | <code>/var/adm/lastlog</code>           | time of last login                                                                                                     |
|                    | <code>/var/adm/loginlog</code>          | record of failed login attempts                                                                                        |
|                    | <code>/var/adm/utmpx</code>             | accounting                                                                                                             |
|                    | <code>/var/adm/wtmpx</code>             | accounting                                                                                                             |
|                    | <code>/var/mail/your-name</code>        | mailbox for user <i>your-name</i>                                                                                      |
|                    | <code>/etc/default/login</code>         | Default value can be set for the following flags in <code>/etc/default/login</code> . For example:<br>TIMEZONE=EST5EDT |
|                    | TIMEZONE                                | Sets the TZ environment variable of the shell (see <code>environ(5)</code> ).                                          |
|                    | HZ                                      | Sets the HZ environment variable of the shell.                                                                         |

**ULIMIT**

Sets the file size limit for the login. Units are disk blocks. Default is zero (no limit).

**CONSOLE**

If set, root can login on that device only. This will not prevent execution of remote commands with `rsh(1)`. Comment out this line to allow login by root.

**PASSREQ**

Determines if login requires a non-null password.

**ALTSHELL**

Determines if login should set the `SHELL` environment variable.

**PATH**

Sets the initial shell `PATH` variable.

**SUPATH**

Sets the initial shell `PATH` variable for root.

**TIMEOUT**

Sets the number of seconds (between 0 and 900) to wait before abandoning a login session.

**UMASK**

Sets the initial shell file creation mode mask. See `umask(1)`.

**SYSLOG**

Determines whether the `syslog(3C)` `LOG_AUTH` facility should be used to log all root logins at level `LOG_NOTICE` and multiple failed login attempts at `LOG_CRIT`.

**DISABLETIME**

If present, and greater than zero, the number of seconds that `login` will wait after `RETRIES` failed attempts or the PAM framework returns `PAM_ABORT`. Default is 20 seconds. Minimum is 0 seconds. No maximum is imposed.

**SLEEPTIME**

If present, sets the number of seconds to wait before the login failure message is printed to the screen. This is for any login failure other than `PAM_ABORT`. Another login attempt is allowed, providing `RETRIES` has not been reached or the PAM framework is returned `PAM_MAXTRIES`. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

## login(1)

### RETRIES

Sets the number of retries for logging in (see pam(3PAM)). The default is 5.

### SYSLOG\_FAILED\_LOGINS

Used to determine how many failed login attempts will be allowed by the system before a failed login message is logged, using the syslog(3C) LOG\_NOTICE facility. For example, if the variable is set to 0, login will log *all* failed login attempts.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** csh(1), exit(1), ksh(1), mail(1), mailx(1), newgrp(1), passwd(1), rlogin(1), rsh(1), sh(1), shell\_builtins(1), telnet(1), umask(1), in.rlogind(1M), in.telnetd(1M), logins(1M), quota(1M), su(1M), syslogd(1M), useradd(1M), userdel(1M), pam(3PAM), rcmd(3SOCKET), syslog(3C), ttyname(3C), auth\_attr(4), exec\_attr(4), hosts.equiv(4), issue(4), logindevperm(4), loginlog(4), nologin(4), nsswitch.conf(4), pam.conf(4), passwd(4), profile(4), shadow(4), user\_attr(4), utmpx(4), wtmpx(4), attributes(5), environ(5), pam\_unix\_account(5), pam\_unix\_auth(5), pam\_unix\_session(5), pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), termio(7I)

**DIAGNOSTICS** Login incorrect  
The user name or the password cannot be matched.

Not on system console  
Root login denied. Check the CONSOLE setting in /etc/default/login.

No directory! Logging in with home=  
The user's home directory named in the passwd(4) database cannot be found or has the wrong permissions. Contact your system administrator.

No shell  
Cannot execute the shell named in the passwd(4) database. Contact your system administrator.

NO LOGINS: System going down in *N* minutes  
The machine is in the process of being shut down and logins have been disabled.

**WARNINGS** Users with a UID greater than 76695844 are not subject to password aging, and the system does not record their last login time.

If you use the `CONSOLE` setting to disable root logins, you should arrange that remote command execution by root is also disabled. See `rsh(1)`, `rcmd(3SOCKET)`, and `hosts.equiv(4)` for further details.

**NOTES** The `pam_unix(5)` module might not be supported in a future release. Similar functionality is provided by `pam_unix_account(5)`, `pam_unix_auth(5)`, `pam_unix_session(5)`, `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, and `pam_passwd_auth(5)`.

## logname(1)

|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>                  | logname – return user’s login name                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>              | <b>logname</b>                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>           | The logname utility will write the user’s login name to standard output. The login name is the string that would be returned by the <code>getlogin(3C)</code> function. Under the conditions where <code>getlogin()</code> would fail, logname will write a diagnostic message to standard error and exit with a non-zero exit status. |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of logname: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.                                                                                                                                                            |
| <b>EXIT STATUS</b>           | The following error values are returned:<br><br>0                               Successful completion.<br><br>>0                               An error occurred.                                                                                                                                                                      |
| <b>FILES</b>                 | <code>/etc/profile</code> environment for user at login time<br><code>/var/adm/utmpx</code> user and accounting information                                                                                                                                                                                                            |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                           |

look(1)

**NAME** look – find words in the system dictionary or lines in a sorted list

**SYNOPSIS** /usr/bin/look [-d] [-f] [-tc] *string* [*filename*]

**DESCRIPTION** The look command consults a sorted *filename* and prints all lines that begin with *string*.

If no *filename* is specified, look uses /usr/share/lib/dict/words with collating sequence -df.

look limits the length of a word to search for to 256 characters.

**OPTIONS**

- d Dictionary order. Only letters, digits, TAB and SPACE characters are used in comparisons.
- f Fold case. Upper case letters are not distinguished from lower case in comparisons.
- tc Set termination character. All characters to the right of *c* in *string* are ignored.

**FILES** /usr/share/lib/dict/words spelling list

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>SYNOPSIS</b>    | <b>lookbib</b> <i>database</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a ‘%’, followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with ‘%’.</p> <p>The <code>lookbib</code> utility uses an inverted index made by <code>indxbib</code> to find sets of bibliographic references. It reads keywords typed after the ‘&gt;’ prompt on the terminal, and retrieves records containing all these keywords. If nothing matches, nothing is returned except another ‘&gt;’ prompt.</p> <p>It is possible to search multiple databases, as long as they have a common index made by <code>indxbib(1)</code>. In that case, only the first argument given to <code>indxbib</code> is specified to <code>lookbib</code>.</p> <p>If <code>lookbib</code> does not find the index files (the <code>.i[abc]</code> files), it looks for a reference file with the same name as the argument, without the suffixes. It creates a file with a <code>.ig</code> suffix, suitable for use with <code>fgrep</code> (see <code>grep(1)</code>). <code>lookbib</code> then uses this <code>fgrep</code> file to find references. This method is simpler to use, but the <code>.ig</code> file is slower to use than the <code>.i[abc]</code> files, and does not allow the use of multiple reference files.</p> |                |                 |              |         |
| <b>FILES</b>       | <p><code>x.ia</code></p> <p><code>x.ib</code></p> <p><code>x.ic</code>      index files</p> <p><code>x.ig</code>      reference file</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>The input is one or more object or library archive <i>filenames</i> (see <a href="#">ar(1)</a>). The standard output is a list of pairs of object file or archive member names; the first file of the pair refers to external identifiers defined in the second. The output may be processed by <a href="#">tsort(1)</a> to find an ordering of a library suitable for one-pass access by <a href="#">ld</a>. Note that the link editor <a href="#">ld</a> is capable of multiple passes over an archive in the portable archive format (see <a href="#">ar(3HEAD)</a>) and does not require that <a href="#">lorder</a> be used when building an archive. The usage of the <a href="#">lorder</a> command may, however, allow for a more efficient access of the archive during the link edit process.</p> <p>The following example builds a new library from existing <code>.o</code> files.</p> <pre>ar -cr library `lorder *.o   tsort `</pre> |                |                 |                |                 |        |                                                                                                                                              |

|                                  | Specify <i>destination</i> using atomic, POSIX-style ( <i>server:destination</i> ), or Federated Naming Service (FNS) ( <i>.../service/printer/...</i> ) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names and <code>standards(5)</code> for information regarding POSIX.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-f form-name</code>        | Prints <i>file</i> on <i>form-name</i> . The LP print service ensures that the form is mounted on the printer. The print request is rejected if the printer does not support <i>form-name</i> , if <i>form-name</i> is not defined for the system, or if the user is not allowed to use <i>form-name</i> (see <code>lpforms(1M)</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-H special-handling</code> | Prints the print request according to the value of <i>special-handling</i> . The following <i>special-handling</i> values are acceptable:<br><br><code>hold</code><br>Do not print the print request until notified. If printing has already begun, stop it. Other print requests will go ahead of a request that has been put on hold ( <i>held print request</i> ) until the print request is resumed.<br><br><code>resume</code><br>Resume a held print request. If the print request had begun to print when held, it will be the next print request printed, unless it is superseded by an <i>immediate</i> print request.<br><br><code>immediate</code><br>Print the print request next. If more than one print request is assigned, the most recent print request is printed next. If a print request is currently printing on the desired printer, a <code>hold</code> request must be issued to allow the immediate request to print. The <code>immediate</code> request is only available to LP administrators. |
| <code>-i request-ID</code>       | Changes options for the print request identified by <i>request-ID</i> . There must be a space between <code>-i</code> and <i>request-ID</i> . This option applies only to jobs that are in a local queue on a print server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-m</code>                  | Sends mail after <i>file</i> has printed (see <code>mail(1)</code> ). By default, no mail is sent upon normal completion of a print request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-n number</code>           | Prints a specific number of copies of <i>file</i> . Specify <i>number</i> as a digit. The default for <i>number</i> is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

-o *option*

Specifies printer-dependent *options*. Specify several options by specifying -o *option* multiple times (-o *option* -o *option* -o *option* ). Printer-dependent options may also be specified using the -o keyletter once, followed by a list of options enclosed in double quotes (-o " *option option option* "). The following options are valid:

nobanner

Does not print a banner page with the request. This option can be disallowed by the LP administrator.

nofilebreak

Prints multiple files without inserting a form feed between them.

length=*number*i | *number*c | *number*

Prints the print request with pages of a specific length in inches, centimeters, or number of lines. Append the letter *i* for inches or *c* for centimeters to *number*. Indicate the number of lines by specifying *number* alone. length=66 indicates a page length of 66 lines. length=11*i* indicates a page length of 11 inches. length=27.94*c* indicates a page length of 27.94 centimeters.

This option may not be used with the -f option.

width=*number*i | *number*c | *number*

Prints the print request with pages of a specific width in inches, centimeters, or number of columns. Append the letter *i* for inches or *c* for centimeters to *number*. Indicate the number of columns by specifying *number* alone. width=65 indicates a page width of 65 columns. width=6.5*i* indicates a page width of 6.5 inches. width=10*c* indicates a page width of 10 centimeters.

This option may not be used with the -f option.

lpi=*number*

Prints the print request with the line pitch set to *number* lines in an inch. Use *number* to specify the number of lines in an inch.

This option may not be used with the -f option.

cpi=*n* | *pica* | *elite* | *compressed*

Prints the print request with the character pitch set to *number* characters in an inch. Use *number* to specify the number of characters in an inch. Use

## lp(1)

|                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                | <p><code>pica</code> to set character pitch to pica (10 characters per inch), or <code>elite</code> to set character pitch to elite (12 characters per inch) Use <code>compressed</code> to set character pitch to as many characters as the printer can handle. There is no standard number of characters per inch for all printers; see the <code>terminfo</code> database (see <code>terminfo(4)</code>) for the default character pitch for your printer. This option may not be used with the <code>-f</code> option.</p>                                                                                                                          |
|                                                                | <p><code>stty=stty-option-list</code><br/>Prints the request using a list of options valid for the <code>stty</code> command (see <code>stty(1)</code>). Enclose the list in single quotes ( <code>' '</code> ) if it contains blanks.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-P page-list</code>                                      | <p>Prints the pages specified in <i>page-list</i> in ascending order. Specify <i>page-list</i> as a of range of numbers, single page number, or a combination of both.</p> <p>The <code>-P</code> option can only be used if there is a filter available to handle it; otherwise, the print request will be rejected.</p>                                                                                                                                                                                                                                                                                                                               |
| <code>-p</code>                                                | <p>Enables notification on completion of the print request. Delivery of the notification is dependent on additional software.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>-q priority-level</code>                                 | <p>Assigns the print request a priority in the print queue. Specify <i>priority-level</i> as an integer between from 0 and 39. Use 0 to indicate the highest priority; 39 to indicate the lowest priority. If no priority is specified, the default priority for a print service is assigned by the LP administrator. The LP administrator may also assign a default priority to individual users.</p>                                                                                                                                                                                                                                                  |
| <code>-s</code>                                                | <p>Suppresses the display of messages sent from <code>lp</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-S character-set  </code><br><code>-S print-wheel</code> | <p>Prints the request using the <i>character-set</i> or <i>print-wheel</i>. If a form was requested and requires a character set or print wheel other than the one specified with the <code>-S</code> option, the request is rejected. Printers using mountable print wheels or font cartridges use the print wheel or font cartridge mounted at the time of the print request, unless the <code>-S</code> option is specified.</p> <p>Printers Using Print Wheels: If <i>print wheel</i> is not one listed by the LP administrator as acceptable for the printer the request is rejected unless the print wheel is already mounted on the printer.</p> |

Printers Using Selectable or Programmable Character Sets: If the `-S` option is not specified, `lp` uses the standard character set. If *character-set* is not defined in the `terminfo` database for the printer (see `terminfo(4)`), or is not an alias defined by the LP administrator, the request is rejected.

- `-t title` Prints a title on the banner page of the output. Enclose *title* in quotes if it contains blanks. If *title* is not specified, the name of the file is printed on the banner page.
- `-T content-type [-r]` Prints the request on a printer that can support the specified *content-type*. If no printer accepts this type directly, a filter will be used to convert the content into an acceptable type. If the `-r` option is specified, a filter will not be used. If `-r` is specified, and no printer accepts the *content-type* directly, the request is rejected. If the *content-type* is not acceptable to any printer, either directly or with a filter, the request is rejected.
- `-w` Writes a message on the user's terminal after the *files* have been printed. If the user is not logged in, then mail will be sent instead.
- `-y mode-list` Prints the request according to the printing modes listed in *mode-list*. The allowed values for *mode-list* are locally defined.
- This option may be used only if there is a filter available to handle it; otherwise, the print request will be rejected.

**OPERANDS** The following operand is supported:

*file* The name of the file to be printed. Specify *file* as a pathname or as a hyphen (`-`) to indicate the standard input. If *file* is not specified, `lp` uses the standard input.

**USAGE** See `largefile(5)` for the description of the behavior of `lp` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `lp`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `NLSPATH`, and `PATH`.

`LC_TIME` Determine the format and contents of date and time strings displayed in the `lp` banner page, if any.

`LPDEST` Determine the destination. If the `LPDEST` environment variable is not set, the `PRINTER` environment variable shall be used. The `-d`

lp(1)

*dest* option takes precedence over LPDEST. Results are undefined when *-d* is not specified and LPDEST contains a value that is not a valid destination name.

**PRINTER** Determine the output device or destination. If the LPDEST and PRINTER environment variables are not set, an unspecified output device is used. The *-d dest* option and the LPDEST environment variable shall take precedence over PRINTER. Results are undefined when *-d* is not specified, LPDEST is unset, and PRINTER contains a value that is not a valid device or destination name.

**TZ** Determine the timezone used to calculate date and time strings displayed in the lp banner page, if any. If TZ is unset or null, an unspecified default timezone shall be used.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
 non-zero An error occurred.

**FILES**

**SEE ALSO** cancel(1), enable(1), lpq(1B), lpr(1B), lprm(1B), lpstat(1), mail(1), postprint(1), pr(1), stty(1), accept(1M), lpadmin(1M), lpfilter(1M), lpforms(1M), lpmove(1M), lpsched(1M), lpshut(1M), lpssystem(1M), lpusers(1M), nsswitch.conf(4), printers(4), printers.conf(4), terminfo(4), attributes(5), environ(5), largefile(5), standards(5)

**NOTES** CSI-capability assumes that printer names are composed of ASCII characters.

Print jobs are assumed to contain one type of data. That type of data is either specified on the command line or autodetected (simple, PostScript) based on the contents of the first file in the job.

Printers that have a 4.x or BSD-based print server, are not configured to handle BSD protocol extensions. `lp` handles print requests sent to such printers in the following ways:

1. Print requests with more than 52 filenames will be truncated to 52 files. `lp` displays a warning message.
2. The `-f`, `-H`, `-o`, `-P`, `-p`, `-q`, `-S`, `-T`, and `-y` options may require a protocol extension to pass to a print server. If `lp` cannot handle the print request, it displays a warning message.

LP administrators enable protocol extensions by setting a printer's `bsdaddr` entry in `/etc/printers.conf`. Changing the `bsdaddr` entry in `/etc/printers.conf` to:

```
destination:bsdaddr=server,destination,Solaris
```

generates a set of BSD print protocol extensions that can be processed by a Solaris print server. `lp` supports only Solaris protocol extensions at this time.

## lpc(1B)

| <b>NAME</b>        | <code>lpc</code> – line printer control program                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/lpc</code> [ <i>command</i> [ <i>parameter...</i> ]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>lpc</code> utility controls the operation of local printers.</p> <p>Use <code>lpc</code> to perform the following functions:</p> <ul style="list-style-type: none"><li>■ start or stop a printer,</li><li>■ disable or enable a printer's spooling queue,</li><li>■ rearrange the order of jobs in a print queue, or</li><li>■ display the status of a printer print queue and printer daemon.</li></ul> <p><code>lpc</code> can be run from the command line or interactively. Specifying <code>lpc</code> with the optional <i>command</i> and <i>parameter</i> arguments causes <code>lpc</code> to interpret the first argument as an <code>lpc</code> command, and all other arguments as parameters to that command. Specifying <code>lpc</code> without arguments causes it to run interactively, prompting the user for <code>lpc</code> commands with <code>lpc&gt;</code>. By redirecting the standard input, <code>lpc</code> can read commands from a file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>USAGE</b>       | <p><code>lpc</code> commands may be typed in their entirety or abbreviated to an unambiguous substring. Some <code>lpc</code> commands are available to all users; others are available only to super-users.</p> <p>All users may execute the following <code>lpc</code> commands:</p> <p>? [<i>command ...</i>]   help [<i>command ...</i>]<br/>Displays a short description of <i>command</i>. <i>command</i> is an <code>lpc</code> command. If <i>command</i> is not specified, displays a list of <code>lpc</code> commands.</p> <p>exit   quit<br/>Exits from <code>lpc</code>.</p> <p>status [all   <i>printer ...</i>]<br/>Displays the status of print daemons and print queues. <i>all</i> specifies that this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <code>printers.conf(4)</code> for information regarding naming conventions for atomic names.</p> <p>Only a super-user may execute the following <code>lpc</code> commands:</p> <p>abort [all   <i>printer ...</i>]<br/>Terminates an active spooling daemon. Disables printing (by preventing new daemons from being started by <code>lpr(1B)</code>) for <i>printer</i>. <i>all</i> specifies this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <code>printers.conf(4)</code> for information regarding naming conventions for atomic names.</p> |

`clean [all | printer ...]`

Removes files created in the print spool directory by the print daemon from *printer*'s print queue. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`disable [all | printer ...]`

Turns off the print queue for *printer*. Prevents new printer jobs from being entered into the print queue for *printer* by `lpr(1B)`. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`down [all | printer ...] [message]`

Turns the queue for *printer* off and disables printing on *printer*. Inserts *message* in the printer status file. *message* does not need to be quoted; multiple arguments to *message* are treated as arguments are to `echo(1)`. Use `down` to take a printer down and inform users. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`enable [all | printer ...]`

Enables `lpr(1B)` to add new jobs in the spool queue. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`restart [all | printer ...]`

Attempts to start a new printer daemon. `restart` is useful when a print daemon dies unexpectedly and leaves jobs in the print queue. `all` specifies that this command is performed on all locally attached printers. *printer* indicates that this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`start [all | printer ...]`

Enables printing. Starts a spooling daemon for the *printer*. `all` specifies that this command is performed on all locally attached printers. *printer* indicates the command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`stop [all | printer ...]`

Stops a spooling daemon after the current job is complete. Disables printing at that time. `all` specifies that this command is performed on all locally attached printers.

## lpc(1B)

*printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`topq printer [request-ID ...] [user ...]`

Moves *request-ID* or print jobs belonging to *user* on *printer* to the beginning of the print queue. Specify *user* as a user's login name. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`up [all | printer ...]`

Turns the queue for *printer* on and enables printing on *printer*. Deletes the message in the printer status file (inserted by `down`). Use `up` to undo the effects of `down`. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**FILES** `/var/spool/lp/*` LP print queue.

`/var/spool/lp/system/pstatus` Printer status information file.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscplp       |

**SEE ALSO** `echo(1)`, `lpq(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `lpsched(1M)`, `lpshut(1M)`, `printers.conf(4)`, `attributes(5)`

**DIAGNOSTICS** Ambiguous command  
Indicates that the `lpc` command or abbreviation matches more than one command.

?Invalid command

Indicates that the `lpc` command or abbreviation is not recognized.

?Privileged command

Indicates that the `lpc` command or abbreviation can be executed only by a super-user.

`lpc: printer` : unknown printer to the print service

Indicates that *printer* does not exist in the LP database. Check that *printer* was correctly specified. Use `lpstat -p` or the `status` command (see `lpstat(1)` or `USAGE`) to check the status of printers.

lpc: error on opening queue to spooler

Indicates that the connection to lpsched failed. Usually means that the printer server has died or is hung. Use /usr/lib/lp/lpsched to check if the printer spooler daemon is running.

lpc: Can't send message to LP print service

lpc: Can't receive message from LP print service

Indicates that the LP print service stopped. Contact the LP administrator.

lpc: Received unexpected message from LP print service

Indicates a problem with the software. Contact the LP administrator.

| <b>NAME</b>        | lpq – display the content of a print queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/lpq [-P <i>destination</i>] [-l] [+ [<i>interval</i>]] [<i>request-ID</i>...] [<i>user</i>...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>The <code>lpq</code> utility displays the information about the contents of a print queue. A print queue is comprised of print requests that are waiting in the process of being printed.</p> <p><code>lpq</code> displays the following information to the standard output:</p> <ul style="list-style-type: none"><li>■ the username of the person associated with a print request,</li><li>■ the position of a print request in the print queue,</li><li>■ the name of file or files comprising a print request,</li><li>■ the job number of a print request, and</li><li>■ the size of the file requested by a print request. File size is reported in bytes.</li></ul> <p>Normally, only as much information as will fit on one line is displayed. If the name of the input file associated with a print request is not available, the input file field indicates the standard input.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-P <i>destination</i></code> Displays information about printer or class of printers (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic, POSIX-style (<code>server:destination</code>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p><code>-l</code> Displays information in long format. Long format includes the name of the host from which a print request originated in the display.</p> <p><code>+ [<i>interval</i>]</code> Displays information at specific time intervals. Stops displaying information when the print queue is empty. Clears the screen before reporting displaying the print queue. Specify <i>interval</i> as the number of seconds between displays. If <i>interval</i> is not specified only executes once.</p>                                                                                           |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><code><i>request-ID</i></code> The job number associated with a print request.</p> <p><code><i>user</i></code> The name of the user about whose jobs <code>lpq</code> reports information. Specify <i>user</i> as a valid username.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EXIT STATUS</b> | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

0 Successful completion.

non-zero An error occurred.

| <b>DESCRIPTION</b>    | <p>The <code>lpr</code> utility submits print requests to a destination. <code>lpr</code> prints files (<i>file</i>) and associated information, collectively called a <i>print request</i>. If <i>file</i> is not specified, <code>lpr</code> assumes the standard input.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p> <p>Print requests with more than 52 <i>files</i> specified will be truncated to 52 files. <code>lpr</code> displays a warning message.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |                                                                                                                      |                 |                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                                                                                                    |                  |                                                                                                                                                                            |
| <b>OPTIONS</b>        | <p>The following options are supported:</p> <table><tr><td>-P <i>destination</i></td><td>Prints <i>file</i> on a specific printer or class of printers(see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</td></tr><tr><td>-# <i>number</i></td><td>Prints a specific number of copies. Specify <i>number</i> as a positive integer. The default for <i>number</i> is 1.</td></tr><tr><td>-C <i>class</i></td><td>Prints <i>class</i> as the job classification on the banner page of the output. Enclose <i>class</i> in double quotes if it contains blanks. If <i>class</i> is not specified, the name of the system (as returned by <code>hostname</code>) is printed as the job classification. See <code>hostname(1)</code>.</td></tr><tr><td>-J <i>job</i></td><td>Prints <i>job</i> as the <i>job name</i> on the banner page of the output. Enclose <i>job</i> in double quotes if it contains blanks. If <i>job</i> is not specified, <i>file</i> (or in the case of multiple files, the first <i>file</i> specified on the command line) is printed as the job name on the banner page of the output.</td></tr><tr><td>-T <i>title</i></td><td>Prints a title on the page header of the output. Enclose <i>title</i> in double quotes if it contains blanks. The <code>-T</code> option is ignored unless it is specified with the <code>-p</code> filter option.</td></tr><tr><td>-i <i>indent</i></td><td>Indents the output a specific number of SPACE characters. Use <i>indent</i> to indicate the number of SPACE characters to be indented. Specify <i>indent</i> as a positive</td></tr></table> | -P <i>destination</i> | Prints <i>file</i> on a specific printer or class of printers(see <code>lpadmin(1M)</code> ). See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |                                                                                                                      |                 |                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                                                                                                    |                  |                                                                                                                                                                            |
| -# <i>number</i>      | Prints a specific number of copies. Specify <i>number</i> as a positive integer. The default for <i>number</i> is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |                                                                                                                      |                 |                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                                                                                                    |                  |                                                                                                                                                                            |
| -C <i>class</i>       | Prints <i>class</i> as the job classification on the banner page of the output. Enclose <i>class</i> in double quotes if it contains blanks. If <i>class</i> is not specified, the name of the system (as returned by <code>hostname</code> ) is printed as the job classification. See <code>hostname(1)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |                                                                                                                      |                 |                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                                                                                                    |                  |                                                                                                                                                                            |
| -J <i>job</i>         | Prints <i>job</i> as the <i>job name</i> on the banner page of the output. Enclose <i>job</i> in double quotes if it contains blanks. If <i>job</i> is not specified, <i>file</i> (or in the case of multiple files, the first <i>file</i> specified on the command line) is printed as the job name on the banner page of the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |                                                                                                                      |                 |                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                                                                                                    |                  |                                                                                                                                                                            |
| -T <i>title</i>       | Prints a title on the page header of the output. Enclose <i>title</i> in double quotes if it contains blanks. The <code>-T</code> option is ignored unless it is specified with the <code>-p</code> filter option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |                                                                                                                      |                 |                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                                                                                                    |                  |                                                                                                                                                                            |
| -i <i>indent</i>      | Indents the output a specific number of SPACE characters. Use <i>indent</i> to indicate the number of SPACE characters to be indented. Specify <i>indent</i> as a positive                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |                                                                                                                      |                 |                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                                                                                                    |                  |                                                                                                                                                                            |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                                                                   |                |                                                    |                |                                                                            |

|                               | integer. If the optional argument to indent is not specified, then eight <code>SPACE</code> characters is the default. The <code>-i</code> option is ignored unless it is specified with the <code>-p</code> filter option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                                                   |                |                                                    |                |                                                                            |
| <code>-1 -2 -3 -4 font</code> | Mounts the specified font in the font position 1, 2, 3, or 4. Specify <i>font</i> as a valid font name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                                                                   |                |                                                    |                |                                                                            |
| <code>-w cols</code>          | Prints <i>file</i> with pages of a specific width. <i>cols</i> indicates the number of columns wide. The <code>-w</code> option is ignored unless it is specified with the <code>-p</code> filter option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                                                   |                |                                                    |                |                                                                            |
| <code>-m</code>               | Sends mail after <i>file</i> has printed. See <code>mail(1)</code> . By default, no mail is sent upon normal completion of a print request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                                                   |                |                                                    |                |                                                                            |
| <code>-h</code>               | Suppresses printing of the banner page of the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                                                                   |                |                                                    |                |                                                                            |
| <code>-s</code>               | Uses full pathnames (as opposed to symbolic links) to <i>file</i> rather than trying to copy them. This means <i>file</i> should not be modified or removed until it has completed printing. Option <code>-s</code> only prevents copies of local files from being made on the local machine. Option <code>-s</code> only works with specified <i>files</i> . If the <code>lpr</code> command is at the end of a pipeline, <i>file</i> is copied to the spool.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                                                                   |                |                                                    |                |                                                                            |
| <code>-filter_option</code>   | <p>Notifies the print spooler that <i>file</i> is not a standard text file. Enables the spooling daemon to use the appropriate filters to print <i>file</i>.</p> <p><i>filter_options</i> offer a standard user interface. All filter options may not be available for, or applicable to, all printers.</p> <p>Specify <i>filter_option</i> as a single character.</p> <p>If <i>filter_option</i> is not specified and the printer can interpret PostScript®, inserting ‘%!’ as the first two characters of <i>file</i> causes <i>file</i> to be interpreted as PostScript.</p> <p>The following filter options are supported:</p> <table border="0"> <tr> <td><code>p</code></td> <td>Use <code>pr</code> to format the files. See <code>pr(1)</code>.</td> </tr> <tr> <td><code>l</code></td> <td>Print control characters and suppress page breaks.</td> </tr> <tr> <td><code>t</code></td> <td><i>file</i> contains <code>troff</code> (cat phototypesetter) binary data.</td> </tr> </table> | <code>p</code> | Use <code>pr</code> to format the files. See <code>pr(1)</code> . | <code>l</code> | Print control characters and suppress page breaks. | <code>t</code> | <i>file</i> contains <code>troff</code> (cat phototypesetter) binary data. |
| <code>p</code>                | Use <code>pr</code> to format the files. See <code>pr(1)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                                                                   |                |                                                    |                |                                                                            |
| <code>l</code>                | Print control characters and suppress page breaks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                                                                   |                |                                                    |                |                                                                            |
| <code>t</code>                | <i>file</i> contains <code>troff</code> (cat phototypesetter) binary data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                                                                   |                |                                                    |                |                                                                            |

lpr(1B)

- n *file* contains `ditroff` data from device independent troff.
- d *file* contains `tex` data in DVI format from Stanford.
- g *file* contains standard plot data produced by `plot(1B)` routines.
- v *file* contains a raster image. *printer* must support an appropriate imaging model such as PostScript in order to print the image.
- c *file* contains data produced by `cifplot`.
- f Interprets the first character of each line as a standard FORTRAN carriage control character.

**OPERANDS** The following operand is supported:

*file* The name of the file to be printed. Specify *file* as a pathname. If *file* is not specified, `lpr` uses the standard input.

**USAGE** See `largefile(5)` for the description of the behavior of `lpr` when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

**FILES**

- `/var/spool/print/.seq` File containing the sequence numbers for job ID assignment.
- `/var/spool/print/[cd]f*` Spooling directories and files.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE     |
|----------------|---------------------|
| Availability   | SUNWscplp           |
| CSI            | Enabled (see NOTES) |

**SEE ALSO** `hostname(1)`, `lp(1)`, `lpc(1B)`, `lpq(1B)`, `lprm(1B)`, `lpstat(1)`, `mail(1)`, `plot(1B)`, `pr(1)`, `troff(1)`, `lpadmin(1M)`, `nsswitch.conf(4)`, `printers(4)`, `printers.conf(4)`, `attributes(5)`, `largefile(5)`, `standards(5)`

**DIAGNOSTICS** `lpr: destination | : unknown destination`  
*destination* was not found in the LP configuration database. Usually this is a typing mistake; however, it may indicate that the *destination* does not exist on the system.

Use `lpstat -p` to display information about the status of the print service.

**NOTES** `lpr` is CSI-enabled except for the *printer* name.

Print jobs are assumed to contain one type of data. That type of data is either specified on the command line or autodetected (simple, PostScript) based on the contents of the first file in the job.

| <b>NAME</b>        | <code>lprm</code> – remove print requests from the print queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/lprm [-P <i>destination</i>] [-] [<i>request-ID...</i>] [<i>user...</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <code>lprm</code> utility removes print requests (<i>request-ID</i>) from the print queue.</p> <p>Without arguments, <code>lprm</code> deletes the current print request. <code>lprm</code> reports the name of the file associated with print requests that it removes. <code>lprm</code> is silent if there are no applicable print requests to remove.</p> <p>Users can only remove print requests associated with their user name. See NOTES. If a super-user executes <code>lprm</code> and specifies the <i>user</i> operand, <code>lprm</code> removes all print requests belonging to the specified user.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p>                                                     |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-P <i>destination</i></code>      The name of the printer or class of printers (see <code>lpadmin(1M)</code>) from which to remove print requests. Specify destination using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<i>../service/printer/..</i>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</li><li><code>-</code>      If a user specifies this option, removes all print requests owned by that user. If a super-user specifies this option, removes all requests in the print queue. Job ownership is determined by the user’s login name and host name on the machine from which <code>lpr</code> was executed. See NOTES.</li></ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported.</p> <ul style="list-style-type: none"><li><i>user</i>      Removes print requests associated with a specific user. Specify <i>user</i> as a valid user name. This option can only be used by a super-user.</li><li><i>request-ID</i>      Removes a specific print request. Specify <i>request-ID</i> as the job number (JOB) associated with a print request and reported by <code>lpq</code>. See <code>lpq(1B)</code>.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                           |

non-zero            An error occurred.

**FILES**            /var/spool/print/[cd]f\*            Spooling directories and files.

**ATTRIBUTES**    See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscplp       |

**SEE ALSO**        lp(1), lpc(1B), lpq(1B), lpr(1B), lpstat(1), lpadmin(1M), nsswitch.conf(4), printers(4), printers.conf(4), attributes(5), standards(5)

**NOTES**            Users can only remove print requests associated with their user name. By default, users can only remove print requests on the host from which the print request was submitted. If a super-user has set `user-equivalence=true` in `/etc/printers.conf` on the print server, users can remove print requests associated with their user name on any host. Super-users can remove print requests on the host from which the print request was submitted. Super-users can also remove print requests from the print server.

| <b>NAME</b>        | lpstat – print information about the status of the print service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |    |                                                     |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <b>lpstat</b> [-d] [-r] [-R] [-s] [-t] [-a <i>list</i> ] [-c <i>list</i> ] [-f <i>list</i> ] [-l] [-o <i>list</i> ] [-p <i>list</i> ] [-D] [-l] [-S <i>list</i> ] [-l] [-u <i>login-ID -list</i> ] [-v <i>list</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |    |                                                     |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>The <code>lpstat</code> utility displays information about the current status of the LP print service to standard output.</p> <p>If no options are given, <code>lpstat</code> prints the status of all the user's print requests made by <code>lp</code>. (see <code>lp(1)</code>). Any arguments that are not <i>options</i> are assumed to be <i>request-IDs</i> as returned by <code>lp</code>. The <code>lpstat</code> command prints the status of such requests. <i>options</i> may appear in any order and may be repeated and intermixed with other arguments. Some key letters may be followed by an optional <i>list</i> that can be in one of two forms: a list of items separated from one another by a comma, or a list of items separated from one another by spaces enclosed in quotes. For example:</p> <pre>example% lpstat -u "user1 user2 user3"</pre> <p>Specifying <code>all</code> after any key letter that takes <i>list</i> as an argument causes all information relevant to the key letter to be printed. For example, the command:</p> <pre>example% lpstat -o all</pre> <p>prints the status of all output requests.</p> <p>The omission of a <i>list</i> following such key letters causes all information relevant to the key letter to be printed. For example, the command:</p> <pre>example% lpstat -o</pre> <p>prints the status of all output requests.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p> |    |                                                     |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The following options are supported on all platforms.</p> <table><tr><td>-d</td><td>Prints the default destination for output requests.</td></tr><tr><td>-o <i>list</i></td><td>Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and request-IDs. The key letter <code>-o</code> may be omitted. Specify printer and class names using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<i>../service/printer/..</i>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | -d | Prints the default destination for output requests. | -o <i>list</i> | Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and request-IDs. The key letter <code>-o</code> may be omitted. Specify printer and class names using atomic, POSIX-style ( <i>server:destination</i> ), or Federated Naming Service (FNS) ( <i>../service/printer/..</i> ) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX. |
| -d                 | Prints the default destination for output requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                                                     |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| -o <i>list</i>     | Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and request-IDs. The key letter <code>-o</code> may be omitted. Specify printer and class names using atomic, POSIX-style ( <i>server:destination</i> ), or Federated Naming Service (FNS) ( <i>../service/printer/..</i> ) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |    |                                                     |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -r                          | Prints the status of the LP request scheduler.                                                                                                                                                                                                                                                                                                                                                                                           |
| -R                          | Prints a number showing the position of each request in the print queue.                                                                                                                                                                                                                                                                                                                                                                 |
| -s                          | Prints a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms currently mounted, and a list of all recognized character sets and print wheels.                                                                                                                                         |
| -t                          | Prints all status information. This includes all the information obtained with the -s option, plus the acceptance and idle/busy status of all printers.                                                                                                                                                                                                                                                                                  |
| -u [ <i>login-ID-list</i> ] | Prints the status of output requests for users. The <i>login-ID-list</i> argument may include any or all of the following constructs:<br><br><i>login-ID</i><br>a user on any system<br><br><i>system_name!login-ID</i><br>a user on system <i>system_name</i><br><br><i>system_name!all</i><br>all users on system <i>system_name</i><br><br><i>all!login-ID</i><br>a user on all systems<br><br><i>all</i><br>all users on all systems |
| -v [ <i>list</i> ]          | Prints the names of printers and the path names of the devices associated with them or remote system names for network printers. <i>list</i> is a list of printer names.                                                                                                                                                                                                                                                                 |

The following options return accurate results only if they are issued from a Solaris 2.6 Operating Environment or compatible version of the LP print server.

|                              |                                                                                                                                                                                                        |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a [ <i>list</i> ]           | Reports whether print destinations are accepting requests. <i>list</i> is a list of intermixed printer names and class names.                                                                          |
| -c [ <i>list</i> ]           | Prints name of all classes and their members. <i>list</i> is a list of class names.                                                                                                                    |
| -f [ <i>list</i> ] [-1]      | Prints a verification that the forms in <i>list</i> are recognized by the LP print service. <i>list</i> is a list of forms; the default is <i>all</i> . The -1 option will list the form descriptions. |
| -p [ <i>list</i> ] [-D] [-1] | Prints the status of printers. <i>list</i> is a list of printer names. If the -D option is given, a brief description is                                                                               |

## lpstat(1)

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         | printed for each printer in <i>list</i> . If the <i>-l</i> option is given and the printer is on the local machine, a full description of each printer's configuration is returned, including the form mounted, the acceptable content and printer types, a printer description, and the interface used.                                                                                                                                                                                                     |
| <i>-s</i> [ <i>list</i> ] [ <i>-l</i> ] | Prints a verification that the character sets or the print wheels specified in <i>list</i> are recognized by the LP print service. Items in <i>list</i> can be character sets or print wheels; the default for the list is <i>all</i> . If the <i>-l</i> option is given, each line is appended by a list of printers that can handle the print wheel or character set. The list also shows whether the print wheel or character set is mounted, or specifies the built-in character set into which it maps. |
| <i>-d</i>                               | Prints the default destination for output requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>-o</i> [ <i>list</i> ]               | Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and <i>request-IDs</i> . The key letter <i>-o</i> may be omitted.                                                                                                                                                                                                                                                                                                                                      |
| <i>-r</i>                               | Prints the status of the LP request scheduler.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>-R</i>                               | Prints a number showing the position of each request in the print queue.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>-s</i>                               | Prints a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms currently mounted, and a list of all recognized character sets and print wheels.                                                                                                                                                                                                             |
| <i>-t</i>                               | Prints all status information. This includes all the information obtained with the <i>-s</i> option, plus the acceptance and idle/busy status of all printers.                                                                                                                                                                                                                                                                                                                                               |
| <i>-u</i> [ <i>login-ID-list</i> ]      | Prints the status of output requests for users. The <i>login-ID-list</i> argument may include any or all of the following constructs:<br><i>login-ID</i><br>a user on any system<br><i>system_name</i> ! <i>login-ID</i><br>a user on system <i>system_name</i><br><i>system_name</i> ! <i>all</i><br>all users on system <i>system_name</i><br><i>all</i> ! <i>login-ID</i><br>a user on all systems                                                                                                        |

all

all users on all systems

**-v** [*list*]Prints the names of printers and the path names of the devices associated with them or remote system names for network printers. *list* is a list of printer names.**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

| <b>NAME</b>        | lptest – generate line printer ripple pattern                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                     |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/lptest</code> [ <i>length</i> [ <i>count</i> ]]                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The <code>lptest</code> utility writes the traditional <i>ripple test</i> pattern to the standard output. In 96 lines, the ripple test pattern prints all 96 printable ASCII characters in each position. The ripple test pattern was originally created to test printers. It is also useful for testing terminals, driving terminal ports, debugging, and performing tasks that require a quick supply of random data.</p> <p>This command is obsolete.</p> |                                                                                                                                     |
| <b>OPTIONS</b>     | <i>length</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Specifies the length of the output line in characters. 79 characters is the default.                                                |
|                    | <i>count</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Specifies the number of output lines. 200 lines is the default. If <i>count</i> is specified, <i>length</i> must also be specified. |
| <b>EXIT STATUS</b> | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                     |
|                    | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Successful completion.                                                                                                              |

| <b>DESCRIPTION</b> | <p>For each <i>file</i> that is a directory, <code>ls</code> lists the contents of the directory. For each <i>file</i> that is an ordinary file, <code>ls</code> repeats its name and any other information requested. The output is sorted alphabetically by default. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments appear before directories and their contents.</p> <p>There are three major listing formats. The default format for output directed to a terminal is multi-column with entries sorted down the columns. The <code>-l</code> option allows single column output and <code>-m</code> enables stream output format. In order to determine output formats for the <code>-C</code>, <code>-x</code>, and <code>-m</code> options, <code>ls</code> uses an environment variable, <code>COLUMNS</code>, to determine the number of character positions available on one output line. If this variable is not set, the <code>terminfo(4)</code> database is used to determine the number of columns, based on the environment variable, <code>TERM</code>. If this information cannot be obtained, 80 columns are assumed.</p> <p>The mode printed under the <code>-l</code> option consists of ten characters. The first character may be one of the following:</p> <table border="0"> <tr><td>d</td><td>The entry is a directory.</td></tr> <tr><td>D</td><td>The entry is a door.</td></tr> <tr><td>l</td><td>The entry is a symbolic link.</td></tr> <tr><td>b</td><td>The entry is a block special file.</td></tr> <tr><td>c</td><td>The entry is a character special file.</td></tr> <tr><td>p</td><td>The entry is a FIFO (or “named pipe”) special file.</td></tr> <tr><td>s</td><td>The entry is an AF_UNIX address family socket.</td></tr> <tr><td>–</td><td>The entry is an ordinary file.</td></tr> </table> <p>The next 9 characters are interpreted as three sets of three bits each. The first set refers to the owner’s permissions; the next to permissions of others in the user-group of the file; and the last to all others. Within each set, the three characters indicate permission to read, to write, and to execute the file as a program, respectively. For a directory, “execute” permission is interpreted to mean permission to search the directory for a specified file. The character after permissions is ACL indication. A plus sign is displayed if there is an ACL associated with the file. Nothing is displayed if there are just permissions.</p> <p><code>ls -l</code> (the long list) prints its output as follows for the POSIX locale:</p> <pre>-rwxrwxrwx+ 1 smith dev 10876 May 16 9:42 part2</pre> | d | The entry is a directory. | D | The entry is a door. | l | The entry is a symbolic link. | b | The entry is a block special file. | c | The entry is a character special file. | p | The entry is a FIFO (or “named pipe”) special file. | s | The entry is an AF_UNIX address family socket. | – | The entry is an ordinary file. |

| p                  | The entry is a FIFO (or “named pipe”) special file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |   |                           |   |                      |   |                               |   |                                    |   |                                        |   |                                                     |   |                                                |   |                                |
| s                  | The entry is an AF_UNIX address family socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |                           |   |                      |   |                               |   |                                    |   |                                        |   |                                                     |   |                                                |   |                                |
| –                  | The entry is an ordinary file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |                           |   |                      |   |                               |   |                                    |   |                                        |   |                                                     |   |                                                |   |                                |

ls(1)

Reading from right to left, you see that the current directory holds one file, named `part2`. Next, the last time that file's contents were modified was 9:42 A.M. on May 16. The file contains 10,876 characters, or bytes. The owner of the file, or the user, belongs to the group `dev` (perhaps indicating "development"), and his or her login name is `smith`. The number, in this case `1`, indicates the number of links to file `part2` (see `cp(1)`). The plus sign indicates that there is an ACL associated with the file. *Note:* If the `-@` option has been specified, the presence of extended attributes will supersede the presence of an ACL and the plus sign will be replaced with an 'at' sign (`@`). Finally, the dash and letters tell you that user, group, and others have permissions to read, write, and execute `part2`.

The execute (`x`) symbol here occupies the third position of the three-character sequence. A `-` in the third position would have indicated a denial of execution permissions.

The permissions are indicated as follows:

|                                                 |                                                                                                          |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <code>r</code>                                  | The file is readable.                                                                                    |
| <code>w</code>                                  | The file is writable.                                                                                    |
| <code>x</code>                                  | The file is executable.                                                                                  |
| <code>-</code>                                  | The indicated permission is <i>not</i> granted.                                                          |
| <code>s</code>                                  | The set-user-ID or set-group-ID bit is on, and the corresponding user or group execution bit is also on. |
| <code>S</code>                                  | Undefined bit-state (the set-user-ID bit is on and the user execution bit is off).                       |
| <code>t</code>                                  | The 1000 (octal) bit, or sticky bit, is on (see <code>chmod(1)</code> ), and execution is on.            |
| <code>T</code>                                  | The 1000 bit is turned on, and execution is off (undefined bit-state).                                   |
| <code>/usr/bin/ls</code><br><code>1</code>      | Mandatory locking occurs during access (the set-group-ID bit is on and the group execution bit is off).  |
| <code>/usr/xpg4/bin/ls</code><br><code>L</code> | Mandatory locking occurs during access (the set-group-ID bit is on and the group execution bit is off).  |

For user and group permissions, the third position is sometimes occupied by a character other than `x` or `-`. `s` also may occupy this position, referring to the state of the set-ID bit, whether it be the user's or the group's. The ability to assume the same ID as the user during execution is, for example, used during login when you begin as root but need to assume the identity of the user you login as.

In the case of the sequence of group permissions, `l` may occupy the third position. `l` refers to mandatory file and record locking. This permission describes a file's ability to allow other files to lock its reading or writing permissions during access.

For others permissions, the third position may be occupied by `t` or `T`. These refer to the state of the sticky bit and execution permissions.

**OPTIONS**

The following options are supported:

- a Lists all entries, including those that begin with a dot (.), which are normally not listed.
- A Lists all entries, including those that begin with a dot (.), with the exception of the working directory (.) and the parent directory (..).
- b Forces printing of non-printable characters to be in the octal \ddd notation.
- c Uses time of last modification of the i-node (file created, mode changed, and so forth) for sorting (-t) or printing (-l or -n).
- C Multi-column output with entries sorted down the columns. This is the default output format.
- d If an argument is a directory, lists only its name (not its contents). Often used with -l to get the status of a directory.
- f Forces each argument to be interpreted as a directory and list the name found in each slot. This option turns off -l, -t, -s, and -r, and turns on -a. The order is the order in which entries appear in the directory.
- F Marks directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (\*), FIFOs with a trailing vertical bar (|), symbolic links with a trailing 'at' sign (@), and AF\_UNIX address family sockets with a trailing equals sign (=).
- g The same as -l, except that the owner is not printed.
- h All sizes are scaled to a human readable format, for example, 14K, 234M, 2.7G, or 3.0T. Scaling is done by repetitively dividing by 1024.
- i For each file, prints the i-node number in the first column of the report.
- l Lists in long format, giving mode, ACL indication, number of links, owner, group, size in bytes, and time of last modification for each file (see above). If the file is a special file, the size field instead contains the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format 'month date year' for the POSIX locale. When the LC\_TIME locale category is not set to the POSIX locale, a different format of the time field may be used. Files modified within six months show 'month date time'. If the file is a symbolic link, the filename is printed followed by "→" and the path name of the referenced file.
- L If an argument is a symbolic link, lists the file or directory the link references rather than the link itself.
- m Streams output format. Files are listed across the page, separated by commas.
- n The same as -l, except that the owner's UID and group's GID numbers are printed, rather than the associated character strings.
- o The same as -l, except that the group is not printed.

ls(1)

- p Puts a slash (/) after each filename if the file is a directory.
- q Forces printing of non-printable characters in file names as the character question mark (?).
- r Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
- R Recursively lists subdirectories encountered.
- s Gives size in blocks, including indirect blocks, for each entry.
- t Sorts by time stamp (latest first) instead of by name. The default is the last modification time. (See -u and -c.)
- u Uses time of last access instead of last modification for sorting (with the -t option) or printing (with the -l option).
- @ The same as -l, except that extended attribute information will supersede ACL information. An @ is displayed after the file permission bits for files that have extended attributes.
- x Multi-column output with entries sorted across rather than down the page.
- l Prints one entry per line of output.

**/usr/bin/ls** Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (ell), -m and -l (ell), -x and -l (ell), -@ and -l (ell). The -l option overrides the other option specified in each pair.

**/usr/xpg4/bin/ls** Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (ell), -m and -l (ell), -x and -l (ell), -@ and -l (ell). The last option specified in each pair determines the output format.

**OPERANDS** The following operand is supported:

*file* A path name of a file to be written. If the file specified is not found, a diagnostic message will be output on standard error.

**USAGE** See `largefile(5)` for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** File permissions

An example of a file's permissions is:

```
-rwxr- -r- -
```

This describes a file that is readable, writable, and executable by the user and readable by the group and others.

Another example of a file's permissions is:

```
-rwsr-xr-x
```

**EXAMPLE 1** File permissions (Continued)

This describes a file that is readable, writable, and executable by the user, readable and executable by the group and others, and allows its user-ID to be assumed, during execution, by the user presently executing it.

Another example of a file's permissions is:

```
-rw-rw1- - -
```

This describes a file that is readable and writable only by the user and the group and can be locked during access.

**EXAMPLE 2** Printing the names of all files

This command prints the names of all files in the current directory, including those that begin with a dot (.), which normally do not print:

```
example% ls -a
```

**EXAMPLE 3** Providing file information

Another example of a command line is:

```
example% ls -aisn
```

This command provides information on all files, including those that begin with a dot (a), the i-number—the memory address of the i-node associated with the file—printed in the left-hand column (i); the size (in blocks) of the files, printed in the column to the right of the i-numbers (s); finally, the report is displayed in the numeric version of the long list, printing the UID (instead of user name) and GID (instead of group name) numbers associated with the files.

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `ls`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLS_PATH`, and `TZ`.

**COLUMNS** Determines the user's preferred column position width for writing multiple text-column output. If this variable contains a string representing a decimal integer, the `ls` utility calculates how many path name text columns to write (see `-C`) based on the width provided. If `COLUMNS` is not set or is invalid, 80 is used. The column width chosen to write the names of files in any given directory will be constant. File names will not be truncated to fit into the multiple text-column output.

ls(1)

**EXIT STATUS** 0 All information was written successfully.  
>0 An error occurred.

**FILES** /etc/group group IDs for `ls -l` and `ls -g`  
/etc/passwd user IDs for `ls -l` and `ls -o`  
/usr/share/lib/terminfo/?/\* terminal information database

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/ls**

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| CSI                 | Enabled         |
| Interface Stability | Stable          |

**/usr/xpg4/bin/ls**

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| CSI                 | Enabled         |
| Interface Stability | Standard        |

**SEE ALSO** `chmod(1)`, `cp(1)`, `setfacl(1)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `fsattr(5)`, `largefile(5)`, `standards(5)`

**NOTES** Unprintable characters in file names may confuse the columnar output options.

The total block count will be incorrect if there are hard links among the files.

The sort order of `ls` output is affected by the locale and can be overridden by the `LC_COLLATE` environment variable. For example, if `LC_COLLATE` equals `C`, dot files appear first, followed by names beginning with upper-case letters, then followed by names beginning with lower-case letters. But if `LC_COLLATE` equals `en_US.ISO8859-1`, then leading dots as well as case are ignored in determining the sort order.

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>NAME</b>              | ls – list the contents of a directory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>          | <code>/usr/ucb/ls [-aAcCdFfgiLLqrRstu1] file...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b>       | For each <i>filename</i> that is a directory, <code>ls</code> lists the contents of the directory; for each <i>filename</i> that is a file, <code>ls</code> repeats its name and any other information requested. By default, the output is sorted alphabetically. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments are processed before directories and their contents.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Permissions Field</b> | <p>The mode printed under the <code>-l</code> option contains 10 characters interpreted as follows. If the first character is:</p> <ul style="list-style-type: none"> <li>d       Entry is a directory.</li> <li>D       Entry is a door.</li> <li>b       Entry is a block-type special file.</li> <li>c       Entry is a character-type special file.</li> <li>l       Entry is a symbolic link.</li> <li>p       Entry is a FIFO (also known as “named pipe”) special file.</li> <li>s       Entry is an AF_UNIX address family socket.</li> <li>–       Entry is a plain file.</li> </ul> <p>The next 9 characters are interpreted as three sets of three bits each. The first set refers to owner permissions; the next refers to permissions to others in the same user-group; and the last refers to all others. Within each set, the three characters indicate permission respectively to read, to write, or to execute the file as a program. For a directory, “execute” permission is interpreted to mean permission to search the directory. The permissions are indicated as follows:</p> <ul style="list-style-type: none"> <li>r       The file is readable.</li> <li>w       The file is writable.</li> <li>x       The file is executable.</li> <li>–       The indicated permission is not granted.</li> </ul> <p>The group-execute permission character is given as <code>s</code> if the file has the set-group-id bit set; likewise the owner-execute permission character is given as <code>S</code> if the file has the set-user-id bit set.</p> <p>The last character of the mode (normally <code>x</code> or <code>'-'</code>) is <code>true</code> if the 1000 bit of the mode is on. See <code>chmod(1)</code> for the meaning of this mode. The indications of set-ID and 1000 bits of the mode are capitalized (<code>S</code> and <code>T</code>, respectively) if the corresponding execute permission is <i>not</i> set.</p> <p>A plus sign (+) appended to the list of permissions indicates that an ACL is associated with the file.</p> |

ls(1B)

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

#### OPTIONS

The following options are supported:

- a Lists all entries; in the absence of this option, entries whose names begin with a `'.'` are *not* listed (except for the privileged user, for whom `ls` normally prints even files that begin with a `'.'`).
- A Same as `-a`, except that `'.'` and `'..'` are not listed.
- c Uses time of last edit (or last mode change) for sorting or printing.
- C Forces multi-column output, with entries sorted down the columns; for `ls`, this is the default when output is to a terminal.
- d If argument is a directory, lists only its name (not its contents); often used with `-l` to get the status of a directory.
- f Forces each argument to be interpreted as a directory and lists the name found in each slot. This option turns off `-l`, `-t`, `-s`, and `-r`, and turns on `-a`; the order is the order in which entries appear in the directory.
- F Marks directories with a trailing slash (`/`), doors with a trailing greater-than sign (`>`), executable files with a trailing asterisk (`*`), FIFOs with a trailing vertical bar (`|`), symbolic links with a trailing at-sign (`@`), and AF\_UNIX address family sockets with a trailing equals sign (`=`).
- g For `ls`, shows the group ownership of the file in a long output.
- i For each file, prints the i-node number in the first column of the report.
- l Lists in long format, giving mode, ACL indication, number of links, owner, size in bytes, and time of last modification for each file. If the file is a special file the size field will instead contain the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format `'month date year'`; files modified within six months show `'month date time'`. If the file is a symbolic link, the pathname of the linked-to file is printed preceded by `'->'`.
- L If argument is a symbolic link, lists the file or directory the link references rather than the link itself.
- q Displays non-graphic characters in filenames as the character `?`; for `ls`, this is the default when output is to a terminal.
- r Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
- R Recursively lists subdirectories encountered.
- s Gives size of each file, including any indirect blocks used to map the file, in kilobytes.
- t Sorts by time modified (latest first) instead of by name.

- u Uses time of last access instead of last modification for sorting (with the `-t` option) and/or printing (with the `-l` option).
- l Forces one entry per line output format; this is the default when output is not to a terminal.

**OPERANDS** The following operand is supported:

*file* A path name of a file to be listed. If the file specified is not found, a diagnostic message will be output on standard error.

**USAGE** See `largefile(5)` for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**FILES** `/etc/group` to get group ID for '`ls -g`'  
`/etc/passwd` to get user IDs for '`ls -l`' and '`ls -o`'

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO** `ls(1)`, `attributes(5)`, `largefile(5)`

**NOTES** `NEWLINE` and `TAB` are considered printing characters in filenames.

The output device is assumed to be 80 columns wide.

The option setting based on whether the output is a teletype is undesirable as '`ls -s`' is much different than '`ls -s | lpr`'. On the other hand, not doing this setting would make old shell scripts which used `ls` almost certain losers.

Unprintable characters in file names may confuse the columnar output options.

| <b>DESCRIPTION</b>      | <p>The m4 utility is a macro processor intended as a front end for C, assembler, and other languages. Each of the argument files is processed in order; if there are no files, or if a file is <code>-</code>, the standard input is read. The processed text is written on the standard output.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Macro Syntax</b>     | <p>Macro calls have the form:</p> <pre>name (arg1,arg2, . . . , argn)</pre> <p>The open parenthesis character ( must immediately follow the name of the macro. If the name of a defined macro is not followed by a (, it is deemed to be a call of that macro with no arguments. Potential macro names consist of alphanumeric characters and underscore (<code>_</code>), where the first character is not a digit.</p> <p>Leading unquoted blanks, TABs, and NEWLINES are ignored while collecting arguments. Left and right single quotes are used to quote strings. The value of a quoted string is the string stripped of the quotes.</p>                                                                                                                  |
| <b>Macro Processing</b> | <p>When a macro name is recognized, its arguments are collected by searching for a matching right parenthesis. If fewer arguments are supplied than are in the macro definition, the trailing arguments are taken to be NULL. Macro evaluation proceeds normally during the collection of the arguments, and any commas or right parentheses that happen to turn up within the value of a nested call are as effective as those in the original input text. After argument collection, the value of the macro is pushed back onto the input stream and rescanned.</p>                                                                                                                                                                                           |
| <b>OPTIONS</b>          | <p>The options and their effects are as follows:</p> <ul style="list-style-type: none"> <li>-Bint      Changes the size of the push-back and argument collection buffers from the default of 4,096.</li> <li>-e         Operates interactively. Interrupts are ignored and the output is unbuffered.</li> <li>-Hint      Changes the size of the symbol table hash array from the default of 199. The size should be prime.</li> <li>-s         Enables line sync output for the C preprocessor (#line . . .)</li> <li>-Sint      Changes the size of the call stack from the default of 100slots. Macros take three slots, and non-macro arguments take one.</li> <li>-Tint      Changes the size of the token buffer from the default of 512bytes.</li> </ul> |

To be effective, the above flags must appear before any file names and before any `-D` or `-U` flags:

`-D name[=val]` Defines *name* to *val* or to NULL in *val*'s absence.  
`-Uname` Undefines *name*.

**OPERANDS** The following operand is supported:

*file* A path name of a text file to be processed. If no *file* is given, or if it is `-`, the standard input is read.

**USAGE** The `m4` utility makes available the following built-in macros. These macros may be redefined, but once this is done the original meaning is lost. Their values are NULL unless otherwise stated.

`changequote` Change quote symbols to the first and second arguments. The symbols may be up to five characters long. `changequote` without arguments restores the original values (that is, `' '`).

`changecom` Change left and right comment markers from the default `#` and `NEWLINE`. With no arguments, the comment mechanism is effectively disabled. With one argument, the left marker becomes the argument and the right marker becomes `NEWLINE`. With two arguments, both markers are affected. Comment markers may be up to five characters long.

`decr` Returns the value of its argument decremented by 1.

`define` The second argument is installed as the value of the macro whose name is the first argument. Each occurrence of `$n` in the replacement text, where *n* is a digit, is replaced by the *n*-th argument. Argument 0 is the name of the macro; missing arguments are replaced by the null string; `$#` is replaced by the number of arguments; `$*` is replaced by a list of all the arguments separated by commas; `$@` is like `$*`, but each argument is quoted (with the current quotes).

`defn` Returns the quoted definition of its argument(s). It is useful for renaming macros, especially built-ins.

`divert` `m4` maintains 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order; initially stream 0 is the current stream. The `divert` macro changes the current output stream to its (digit-string) argument. Output diverted to a stream other than 0 through 9 is discarded.

`divnum` Returns the value of the current output stream.

`dn1` Reads and discards characters up to and including the next `NEWLINE`.

m4(1)

|                         |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | dumpdef  | Prints current names and definitions, for the named items, or for all if no arguments are given.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                         | errprint | Prints its argument on the diagnostic output file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>/usr/ccs/bin/m4</b>  | eval     | Evaluates its argument as an arithmetic expression, using 32-bit signed-integer arithmetic. The following operators are supported: parentheses, unary <code>-</code> , unary <code>+</code> , <code>!</code> , <code>~</code> , <code>*</code> , <code>/</code> , <code>%</code> , <code>+</code> , <code>-</code> , relationals, bitwise <code>&amp;</code> , <code> </code> , <code>&amp;&amp;</code> , and <code>  </code> . Octal and hex numbers may be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.                                                                                                |
| <b>/usr/xpg4/bin/m4</b> | eval     | Evaluates its argument as an arithmetic expression, using 32-bit signed-integer arithmetic. The following operators are supported: parentheses, unary <code>-</code> , unary <code>+</code> , <code>!</code> , <code>~</code> , <code>*</code> , <code>/</code> , <code>%</code> , <code>+</code> , <code>-</code> , <code>&lt;&lt;</code> , <code>&gt;&gt;</code> , relationals, bitwise <code>&amp;</code> , <code> </code> , <code>&amp;&amp;</code> , and <code>  </code> . Precedence and associativity are as in C. Octal and hex numbers may also be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result. |
|                         | ifdef    | If the first argument is defined, the value is the second argument, otherwise the third. If there is no third argument, the value is NULL. The word <code>unix</code> is predefined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                         | ifelse   | This macro has three or more arguments. If the first argument is the same string as the second, then the value is the third argument. If not, and if there are more than four arguments, the process is repeated with arguments 4, 5, 6 and 7. Otherwise, the value is either the fourth string, or, if it is not present, NULL.                                                                                                                                                                                                                                                                                                                                                                                                                |
|                         | include  | Returns the contents of the file named in the argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                         | incr     | Returns the value of its argument incremented by 1. The value of the argument is calculated by interpreting an initial digit-string as a decimal number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                         | index    | Returns the position in its first argument where the second argument begins (zero origin), or <code>-1</code> if the second argument does not occur.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                         | len      | Returns the number of characters in its argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                         | m4exit   | This macro causes immediate exit from m4. Argument 1, if given, is the exit code; the default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                         | m4wrap   | Argument 1 will be pushed back at final EOF. Example:<br><code>m4wrap(`cleanup( )')</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                         | maketemp | Fills in a string of "X" characters in its argument with the current process ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                       |                                                                                                                                                                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>popdef</code>   | Removes current definition of its argument(s), exposing the previous one, if any.                                                                                                                                                                                              |
| <code>pushdef</code>  | Like <code>define</code> , but saves any previous definition.                                                                                                                                                                                                                  |
| <code>shift</code>    | Returns all but its first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will subsequently be performed.                                                                             |
| <code>sinclude</code> | This macro is identical to <code>include</code> , except that it says nothing if the file is inaccessible.                                                                                                                                                                     |
| <code>substr</code>   | Returns a substring of its first argument. The second argument is a zero origin number selecting the first character; the third argument indicates the length of the substring. A missing third argument is taken to be large enough to extend to the end of the first string. |
| <code>syscmd</code>   | This macro executes the command given in the first argument. No value is returned.                                                                                                                                                                                             |
| <code>sysval</code>   | This macro is the return code from the last call to <code>syscmd</code> .                                                                                                                                                                                                      |
| <code>translit</code> | Transliterates the characters in its first argument from the set given by the second argument to the set given by the third. No abbreviations are permitted.                                                                                                                   |
| <code>traceon</code>  | This macro with no arguments, turns on tracing for all macros (including built-ins). Otherwise, turns on tracing for named macros.                                                                                                                                             |
| <code>traceoff</code> | Turns off trace globally and for any macros specified. Macros specifically traced by <code>traceon</code> can be untraced only by specific calls to <code>traceoff</code> .                                                                                                    |
| <code>undefine</code> | Removes the definition of the macro named in its argument.                                                                                                                                                                                                                     |
| <code>undivert</code> | This macro causes immediate output of text from diversions named as arguments, or all diversions if no argument. Text may be undiverted into another diversion. Undiverting discards the diverted text.                                                                        |

## EXAMPLES **EXAMPLE 1** Examples of m4 files

An example of a single m4 input file capable of generating two output files follows. The file `file1.m4` could contain lines such as:

```
if(VER, 1, do_something)
if(VER, 2, do_something)
```

The makefile for the program might include:

```
file1.1.c : file1.m4
 m4 -D VER=1 file1.m4 > file1.1.c
 ...
file1.2.c : file1.m4
```

## m4(1)

### EXAMPLE 1 Examples of m4 files (Continued)

```
m4 -D VER=2 file1.m4 > file1.2.c
...
```

The -U option can be used to undefine VER. If file1.m4 contains:

```
if (VER, 1, do_something)
if (VER, 2, do_something)
ifndef (VER, do_something)
```

then the makefile would contain:

```
file1.0.c : file1.m4
 m4 -U VER file1.m4 > file1.0.c
 ...
file1.1.c : file1.m4
 m4 -D VER=1 file1.m4 > file1.1.c
 ...
file1.2.c : file1.m4
 m4 -D VER=2 file1.m4 > file1.2.c
 ...
```

### ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of m4: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

### EXIT STATUS

The following exit values are returned:

```
0 Successful completion.
>0 An error occurred
```

If the m4exit macro is used, the exit value can be specified by the input file.

### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

#### /usr/ccs/bin/m4

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

#### /usr/xpg4/bin/m4

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| Interface Stability | Standard        |

### SEE ALSO

as(1), attributes(5), environ(5), standards(5)

mach(1)

**NAME** mach – display the processor type of the current host

**SYNOPSIS** mach

**DESCRIPTION** The mach command displays the processor-type of the current host.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** arch(1), uname(1), attributes(5)

**NOTES** mach and uname -p return equivalent values; therefore, Independent Software Vendors (ISV) and others who need to ascertain processor type are encouraged to use uname with the -p option instead of the mach command. The mach command is provided for compatibility with previous releases, but generally its use is discouraged.

## machid(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |     |                                  |         |                                                           |      |                                                           |       |                                                |       |                                                               |     |                                     |      |                                    |      |                                    |       |                                     |     |                                                  |      |                                                  |

| <b>NAME</b>                  | madv.so.1 – madv library                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>              | <code>/usr/lib/madv.so.1</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>           | <p>The <code>madv.so.1</code> shared object provides a means by which the VM advice can be selectively configured for a launched process (or processes) and its descendants. To enable <code>madv.so.1</code>, the following string needs to be present in the environment (see <code>ld.so.1(1)</code>) along with one or more MADV environment variables:</p> <pre>LD_PRELOAD=\$LD_PRELOAD:madv.so.1</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ENVIRONMENT VARIABLES</b> | <p>If the <code>madv.so.1</code> shared object is specified in the <code>LD_PRELOAD</code> list, the following environment variables are read by the <code>madv</code> shared object to determine to which created process(es) to apply the specified advice.</p> <p><code>MADV=advice</code></p> <p><code>MADV</code> specifies the VM advice to use for all heap, shared memory, and <code>mmap</code> regions in the process address space. This advice is applied to all created processes.</p> <p>Values for <i>advice</i> correspond to values in <code>&lt;sys/mman.h&gt;</code> used in <code>madvise(3C)</code> to specify memory access patterns:</p> <ul style="list-style-type: none"><li>normal</li><li>random</li><li>sequential</li><li>access_lwp</li><li>access_many</li><li>access_default</li></ul> <p><code>MADVCFGFILE=config-file</code></p> <p><i>config-file</i> is a text file which contains one or more <code>madv</code> configuration entries of the form:</p> <pre>exec-name exec-args:advice-opts</pre> <p>Advice specified in <i>config-file</i> takes precedence over that specified by the <code>MADV</code> environment variable. When <code>MADVCFGFILE</code> is not set, advice is taken from file <code>/etc/madv.conf</code> if it exists.</p> <p><i>exec-name</i> specifies the name of an application or executable. The corresponding advice is set for newly created processes (see <code>getexecname(3C)</code>) that match the first <i>exec-name</i> found in the file.</p> <p><i>exec-name</i> can be a full pathname, a base name, or a pattern string. See <code>File Name Generation</code> in <code>sh(1)</code> for a discussion of pattern matching.</p> <p><i>exec-args</i> is an optionally specified pattern string to match against arguments. Advice is set only if <i>exec-args</i> is not specified or occurs within the arguments to <i>exec-name</i>.</p> |

*advice-opts* is a comma-separated list specifying the advice for various memory region(s):

|                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>madv=advice</i>                                                                                 | Applies to all heap, shared memory, and mmap regions in the process address space.                                                                                                                                                                                                                                                                                                |
| <i>heap=advice</i>                                                                                 | The heap is defined to be the brk area (see <code>brk(2)</code> ). Applies to the existing heap and for any additional heap memory allocated in the future.                                                                                                                                                                                                                       |
| <i>shm=advice</i><br><i>ism=advice</i><br><i>dism=advice</i>                                       | Shared memory segments (see <code>shmat(2)</code> ) attached using any flags, flag <code>SHM_SHARE_MMU</code> , or flag <code>SHM_PAGEABLE</code> respectively. Options <i>ism</i> and <i>dism</i> take precedence over option <i>shm</i> .                                                                                                                                       |
| <i>map=advice</i><br><i>mapshared=advice</i><br><i>mappprivate=advice</i><br><i>mapanon=advice</i> | Mappings established through <code>mmap(2)</code> using any flags, flag <code>MAP_SHARED</code> , flag <code>MAP_PRIVATE</code> , or flag <code>MAP_ANON</code> , respectively. Options <i>mapshared</i> , <i>mappprivate</i> , and <i>mapanon</i> take precedence over option <i>map</i> . Option <i>mapanon</i> takes precedence over <i>mapshared</i> and <i>mappprivate</i> . |

*MADVERRFILE=pathname*

By default, error messages are logged via `syslog(3C)` using level `LOG_ERR` and facility `LOG_USER`. If *MADVERRFILE* contains a valid *pathname* (such as `/dev/stderr`), error messages will be logged there instead.

## EXAMPLES

### EXAMPLE 1 Applying advice to all ISM segments

The following configuration applies advice to all ISM segments for application `/usr/bin/foo`:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
/usr/bin/foo:ism=access_lwp
```

### EXAMPLE 2 Setting advice for all applications with exception

The following configuration sets advice for all applications with the exception of `ls`.

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADV=access_many
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADV MADVCFGFILE
example$ cat $MADVCFGFILE
ls:
```

madv.so.1(1)

**EXAMPLE 3** Precedence rules (continuation from Example 2)

Because MADVCFGFILE takes precedence over MADV, specifying '\*' (pattern match all) for the *exec-name* of the last madv configuration entry would be equivalent to setting MADV. The following is equivalent to example 2:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
ls:
*:madv=access_many
```

**EXAMPLE 4** Applying advice for different regions

The following configuration applies one type of advice for mmap regions and different advice for heap and shared memory regions for a select set of applications with exec names that begin with foo:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
foo*:madv=access_many,heap=sequential,shm=access_lwp
```

**EXAMPLE 5** Applying advice selectively

The following configuration applies advice for the heap of applications beginning with ora that have ora1 as an argument:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
ora* ora1:heap=access_many
```

**FILES** /etc/madv.conf Configuration file

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE   |
|---------------------|-------------------|
| Availability        | SUNWesu (32-bit)  |
|                     | SUNWesxu (64-bit) |
| Interface Stability | Unstable          |

**SEE ALSO** cat(1), ld.so.1(1), proc(1), sh(1), brk(2), exec(2), fork(2), mmap(2), memcntl(2), shmat(2), getexecname(3C), madvise(3C), syslog(3C), proc(4), attributes(5)

**NOTES** | The advice is inherited. A child process has the same advice as its parent. On `exec()` (see `exec(2)`), the advice is set back to the default system advice unless different advice has been configured via the `madv` shared object.

Advice is only applied to `mmap` regions explicitly created by the user program. Those regions established by the run-time linker or by system libraries making direct system calls (for example, `libthread` allocations for thread stacks) are not affected.

mail(1B)

**NAME** mail, Mail – interactive message processing system

**SYNOPSIS** /usr/ucb/mail ...  
/usr/ucb/Mail ...

**DESCRIPTION** /usr/ucb/mail and /usr/ucb/Mail are provided as links to /usr/bin/mailx.  
See mailx(1) for more information on the usage of these commands.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

/usr/ucb/mail

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>DESCRIPTION</b> | <p>mailcompat is a program to provide SunOS 4.x compatibility for the Solaris mailbox format. You would typically run mailcompat to be able to read mail on a workstation running SunOS 4.x when your mail server is running Solaris.</p> <p>Enabling mailcompat creates an entry in your .forward file, if it exists. If this file does not exist, mailcompat will create it. Disabling mailcompat will remove the entry from the .forward file, and if this was the only entry, will remove the entire file.</p> <p>To execute mailcompat, log onto the Solaris mail server and enter mailcompat on the command line. Answer the queries provided by the program.</p>                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>USAGE</b>       | See largefile(5) for the description of the behavior of mailcompat when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples of the mailcompat feature.</p> <p>The following example enables the mailcompat feature for the user "john".</p> <pre>example% mailcompat This program can be used to store your mail in a format that you can read with SunOS 4.X based mail readers To enable the mailcompat feature a ".forward" file is created. | <b>DESCRIPTION</b> | <p>The mailp utility is a frontend to the mp(1) program. It uses different names to provide various mp options:</p> <table><tr><td>mailp</td><td>Prints out mail messages.</td></tr><tr><td>newsp</td><td>Prints out USENET news articles.</td></tr><tr><td>digestp</td><td>Prints out USENET digest files.</td></tr><tr><td>filep</td><td>Prints out ordinary ASCII files.</td></tr><tr><td>filofaxp</td><td>Prints out in Filofax personal organiser format.</td></tr><tr><td>franklinp</td><td>Prints out in Franklin Planner personal organiser format.</td></tr><tr><td>timemanp</td><td>Prints out in Time Manager personal organiser format.</td></tr><tr><td>timesysp</td><td>Prints out in Time/System International personal organiser format.</td></tr></table> <p>mailp and the associated programs read each <i>filename</i> in sequence and generate a prettified version of the contents. If no filename arguments are provided, mailp reads the standard input.</p> <p>mailp works in two ways. With the -D option, it will work as an X print server client to produce the PDL of the target printer and spool it. With the -d or -P option, it will generate and spool PostScript™ output.</p> | mailp             | Prints out mail messages.                                                                                            | newsp | Prints out USENET news articles.                                       | digestp | Prints out USENET digest files.                                                                                                                                                                | filep | Prints out ordinary ASCII files. | filofaxp | Prints out in Filofax personal organiser format. | franklinp | Prints out in Franklin Planner personal organiser format. | timemanp | Prints out in Time Manager personal organiser format. | timesysp | Prints out in Time/System International personal organiser format. |

| -D                 | Generates the PDL for the target printer and spools it to the printer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                   |                                                                                                                      |       |                                                                        |         |                                                                                                                                                                                                |       |                                  |          |                                                  |           |                                                           |          |                                                       |          |                                                                    |
| -F                 | Instead of printing who the mail article is <i>for</i> , the top header will contain who the mail article is <i>from</i> . This is a useful option for people with their own personal printer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                   |                                                                                                                      |       |                                                                        |         |                                                                                                                                                                                                |       |                                  |          |                                                  |           |                                                           |          |                                                       |          |                                                                    |

- h           Banner printing is disabled. Most of the information that typically appears on the banner sheet is output in the mp banners.
- l           Formats output in landscape mode. Two pages of text will be printed per sheet of paper.
- P *printer*   Same as -d option.
- s *subject*   Uses *subject* as the new subject for the printout. If you are printing ordinary ASCII files which have been specified on the command line, the subject will default to the name of each of these files.

**OPERANDS**   The following operand is supported:

*filename*       The name of the file to be read.

**ENVIRONMENT VARIABLES**   If none of the -d, -D, or -P options is used, mailp uses the PRINTER environment variable to determine the printer to which the output from the mp(1) program is sent. If the PRINTER variable is not found, the default destination is the PostScript™ printer.

**EXIT STATUS**   The following exit values are returned:

- 0           Successful completion.
- 1           An error occurred.

**ATTRIBUTES**   See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmp          |

**SEE ALSO**   mp(1), attributes(5)

**NOTES**   The -P option, which spools the PDL directly to the target printer in mp(1), produces PostScript™ when used in mailp so as to be backward compatible.

| <b>NAME</b>        | mailq – print the mail queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <code>/usr/bin/mailq [-q <i>subarg</i>] [-v]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The mailq utility displays a summary of the mail messages queued for future delivery.</p> <p>The first line displayed for each mail message shows the internal identifier used on this host for the message, the size of the message in bytes, the date and time the message was accepted into the queue, and the envelope sender of the message. The second line of the display shows the error message that caused this message to be retained in the queue. This line will not be displayed if the message is being processed for the first time.</p> <p>The mailq utility used to be identical to <code>sendmail -bp</code>. Now it checks for the authorization attribute, <code>solaris.mail.mailq</code>. If the check for the invoking user succeeds, <code>sendmail -bp</code> is executed with the remaining argument vector. Otherwise, an error message is printed. This authorization attribute is by default enabled for all users. It can be disabled by modifying the Basic Solaris User entry in <code>prof_attr(4)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-qp[<i>time</i>]</code> Similar to <code>-qtime</code>, except that instead of periodically forking a child to process the queue, <code>sendmail</code> forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time is given as the argument. The sleep time default is 1 second. The process will always sleep at least 5 seconds if the queue was empty in the previous queue run.</li><li><code>-qf</code> Processes saved messages in the queue once and does not <code>fork()</code>, but runs in the foreground.</li><li><code>-qG <i>name</i></code> Processes jobs in the queue group called <i>name</i> only.</li><li><code>-q[!]I <i>substr</i></code> Limits processed jobs to those containing <i>substr</i> as a substring of the queue id, or not when <code>!</code> is specified.</li><li><code>-q[!]R <i>substr</i></code> Limits processed jobs to those containing <i>substr</i> as a substring of one of the recipients, or not when <code>!</code> is specified.</li><li><code>-q[!]S <i>substr</i></code> Limits processed jobs to those containing <i>substr</i> as a substring of the sender, or not when <code>!</code> is specified.</li><li><code>-v</code> Prints verbose information. This adds the priority of the message and a single character indicator (+ or blank) indicating whether a warning message has been sent on the first line of the message. Additionally, extra lines may be intermixed with the recipients that indicate the "controlling user" information. This shows who will own any programs that are executed on behalf of this message and the name of the alias this command is expanded from, if any.</li></ul> |

| <b>DESCRIPTION</b>       | <p>The mailstats utility prints out the statistics collected by the sendmail(1M) program on mailer usage. These statistics are collected if the file indicated by the StatusFile configuration option of sendmail (defined in /etc/mail/sendmail.cf) exists. The default statistics file is /etc/mail/statistics.</p> <p>To enable mailstats, you must, as root, touch /etc/mail/statistics. See the StatusFile processing option in sendmail(1M).</p> <p>mailstats first prints the time that the statistics file was created and the last time it was modified. Then, the statistics for each mailer are displayed on a single line, each with the following whitespace-separated fields:</p> <table><tr><td>M</td><td>The mailer number.</td></tr><tr><td>msgsfr</td><td>Number of messages from the mailer.</td></tr><tr><td>bytes_from</td><td>Kbytes from the mailer.</td></tr><tr><td>msgsto</td><td>Number of messages to the mailer.</td></tr><tr><td>bytes_to</td><td>Kbytes to the mailer.</td></tr><tr><td>msgsjrej</td><td>Number of messages rejected by the mailer.</td></tr><tr><td>msgsdisc</td><td>Number of messages discarded by the mailer.</td></tr><tr><td>Mailer</td><td>The name of the mailer.</td></tr></table> <p>After this display, a line totaling the values for all of the mailers is displayed, separated from the previous information by a line containing only equal sign (=) characters.</p> <p>To reinitialize the statistics file once a night, add an entry to root's crontab(1):</p> <pre>mailstats -p &gt; /dev/null</pre> | M  | The mailer number.                                                         | msgsfr               | Number of messages from the mailer.      | bytes_from               | Kbytes from the mailer.               | msgsto | Number of messages to the mailer.                      | bytes_to | Kbytes to the mailer.                                              | msgsjrej | Number of messages rejected by the mailer. | msgsdisc | Number of messages discarded by the mailer. | Mailer | The name of the mailer. |
| M                        | The mailer number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |    |                                                                            |                      |                                          |                          |                                       |        |                                                        |          |                                                                    |          |                                            |          |                                             |        |                         |

-P Outputs information in program-readable mode without clearing statistics.

**USAGE** See `largefile(5)` for the description of the behavior of `mailstats` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

| <b>NAME</b>        | mailx, mail – interactive message processing system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <b>mailx</b> [-BdeHiInNURvV~] [-f <i>file</i>   + <i>folder</i> ] [-T <i>file</i> ] [-u <i>user</i> ]<br><b>mailx</b> [-BdFintUv~] [-b <i>bcc</i> ] [-c <i>cc</i> ] [-h <i>number</i> ] [-r <i>address</i> ] [-s <i>subject</i> ]<br><i>recipient...</i><br><b>/usr/ucb/mail</b> ...<br><b>/usr/ucb/Mail</b> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The mail utilities listed above provide a comfortable, flexible environment for sending and receiving mail messages electronically.</p> <p>When reading mail, the mail utilities provide commands to facilitate saving, deleting, and responding to messages. When sending mail, the mail utilities allow editing, reviewing and other modification of the message as it is entered.</p> <p>Incoming mail is stored in a standard file for each user, called the <code>mailbox</code> for that user. When the mail utilities are called to read messages, the <code>mailbox</code> is the default place to find them. As messages are read, they are marked to be moved to a secondary file for storage, unless specific action is taken, so that the messages need not be seen again. This secondary file is called the <code>mbox</code> and is normally located in the user's <code>HOME</code> directory (see <code>MBOX</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file). Messages can be saved in other secondary files named by the user. Messages remain in a secondary file until forcibly removed.</p> <p>The user can access a secondary file by using the <code>-f</code> option. Messages in the secondary file can then be read or otherwise processed using the same Commands as in the primary <code>mailbox</code>. This gives rise within these pages to the notion of a current <code>mailbox</code>.</p> |
| <b>OPTIONS</b>     | <p>On the command line options start with a dash (-). Any other arguments are taken to be destinations (recipients). If no recipients are specified, <code>mailx</code> attempts to read messages from the <code>mailbox</code>.</p> <p>-B Do not buffer standard input or standard output.</p> <p>-b <i>bcc</i> Set the blind carbon copy list to <i>bcc</i>. <i>bcc</i> should be enclosed in quotes if it contains more than one name.</p> <p>-c <i>cc</i> Set the carbon copy list to <i>cc</i>. <i>cc</i> should be enclosed in quotes if it contains more than one name.</p> <p>-d Turn on debugging output. (Neither particularly interesting nor recommended.)</p> <p>-e Test for the presence of mail. <code>mailx</code> prints nothing and exits with a successful return code if there is mail to read.</p> <p>-F Record the message in a file named after the first recipient. Overrides the <code>record</code> variable, if set (see <code>Internal Variables</code>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                        |                                                                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f <i>[file]</i>       | Read messages from <i>file</i> instead of mailbox. If no <i>file</i> is specified, the mbox is used.                                                                               |
| -f [ + <i>folder</i> ] | Use the file <i>folder</i> in the folder directory (same as the <code>folder</code> command). The name of this directory is listed in the <code>folder</code> variable.            |
| -H                     | Print header summary only.                                                                                                                                                         |
| -h <i>number</i>       | The number of network “hops” made so far. This is provided for network software to avoid infinite delivery loops. This option and its argument are passed to the delivery program. |
| -I                     | Include the newsgroup and article-id header lines when printing mail messages. This option requires the <code>-f</code> option to be specified.                                    |
| -i                     | Ignore interrupts. See also <code>ignore</code> in Internal Variables.                                                                                                             |
| -N                     | Do not print initial header summary.                                                                                                                                               |
| -n                     | Do not initialize from the system default <code>mailx.rc</code> or <code>Mail.rc</code> file. See USAGE.                                                                           |
| -r <i>address</i>      | Use <i>address</i> as the return address when invoking the delivery program. All tilde commands are disabled. This option and its argument is passed to the delivery program.      |
| -s <i>subject</i>      | Set the Subject header field to <i>subject</i> . <i>subject</i> should be enclosed in quotes if it contains embedded white space.                                                  |
| -T <i>file</i>         | Message-id and article-id header lines are recorded in <i>file</i> after the message is read. This option also sets the <code>-I</code> option.                                    |
| -t                     | Scan the input for <code>To:</code> , <code>Cc:</code> , and <code>Bcc:</code> fields. Any recipients on the command line will be ignored.                                         |
| -U                     | Convert UUCP-style addresses to internet standards. Overrides the <code>conv</code> environment variable.                                                                          |
| -u <i>user</i>         | Read <i>user</i> ’s mailbox. This is only effective if <i>user</i> ’s mailbox is not read protected.                                                                               |
| -V                     | Print the mailx version number and exit.                                                                                                                                           |
| -v                     | Pass the <code>-v</code> flag to <code>sendmail(1M)</code> .                                                                                                                       |
| -~                     | Interpret tilde escapes in the input even if not reading from a tty.                                                                                                               |

**OPERANDS** The following operands are supported:

*recipient* Addressee of message.

**Starting Mail** At startup time, mailx executes the system startup file `/etc/mail/mailx.rc`. If invoked as `mail` or `Mail`, the system startup file `/etc/mail/Mail.rc` is used instead.

## mailx(1)

The system startup file sets up initial display options and alias lists and assigns values to some internal variables. These variables are flags and valued parameters which are set and cleared using the `set` and `unset` commands. See `Internal Variables`.

With the following exceptions, regular commands are legal inside startup files: `!`, `Copy`, `edit`, `followup`, `Followup`, `hold`, `mail`, `preserve`, `reply`, `Reply`, `shell`, and `visual`. An error in the startup file causes the remaining lines in the file to be ignored.

After executing the system startup file, the mail utilities execute the optional personal startup file `$HOME/.mailrc`, wherein the user can override the values of the internal variables as set by the system startup file.

If the `-n` option is specified, however, the mail utilities do not execute the system startup file.

Many system administrators include the commands

```
set appenddeadletter
unset replyall
unset pipeignore
```

in the system startup files (to be compatible with past Solaris behavior), but this does not meet standards requirements for `mailx`. To get standard behavior for `mailx`, users should use the `-n` option or include the following commands in a personal startup file:

```
unset appenddeadletter
set replyall
set pipeignore
```

When reading mail, the mail utilities are in *command mode*. A header summary of the first several messages is displayed, followed by a prompt indicating the mail utilities can accept regular commands (see `Commands` below). When sending mail, the mail utilities are in *input mode*. If no subject is specified on the command line, and the `asksub` variable is set, a prompt for the subject is printed.

As the message is typed, the mail utilities read the message and store it in a temporary file. Commands may be entered by beginning a line with the tilde (`~`) escape character followed by a single command letter and optional arguments. See `Tilde Escapes` for a summary of these commands.

### Reading Mail

Each message is assigned a sequential number, and there is at any time the notion of a current message, marked by a right angle bracket (`>`) in the header summary. Many commands take an optional list of messages (*message-list*) to operate on. In most cases, the current message is set to the highest-numbered message in the list after the command is finished executing.

The default for *message-list* is the current message. A *message-list* is a list of message identifiers separated by spaces, which may include:

*n*                      Message number *n*.

|                |                                                                                                                                                                                                                                                                                                                |   |                  |   |              |   |              |   |               |   |                 |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|------------------|---|--------------|---|--------------|---|---------------|---|-----------------|
| .              | The current message.                                                                                                                                                                                                                                                                                           |   |                  |   |              |   |              |   |               |   |                 |
| ^              | The first undeleted message.                                                                                                                                                                                                                                                                                   |   |                  |   |              |   |              |   |               |   |                 |
| \$             | The last message.                                                                                                                                                                                                                                                                                              |   |                  |   |              |   |              |   |               |   |                 |
| *              | All messages.                                                                                                                                                                                                                                                                                                  |   |                  |   |              |   |              |   |               |   |                 |
| +              | The next undeleted message.                                                                                                                                                                                                                                                                                    |   |                  |   |              |   |              |   |               |   |                 |
| -              | The previous undeleted message.                                                                                                                                                                                                                                                                                |   |                  |   |              |   |              |   |               |   |                 |
| <i>n-m</i>     | An inclusive range of message numbers.                                                                                                                                                                                                                                                                         |   |                  |   |              |   |              |   |               |   |                 |
| <i>user</i>    | All messages from <i>user</i> .                                                                                                                                                                                                                                                                                |   |                  |   |              |   |              |   |               |   |                 |
| <i>/string</i> | All messages with <i>string</i> in the Subject line (case ignored).                                                                                                                                                                                                                                            |   |                  |   |              |   |              |   |               |   |                 |
| <i>:c</i>      | All messages of type <i>c</i> , where <i>c</i> is one of: <table> <tr> <td>d</td> <td>deleted messages</td> </tr> <tr> <td>n</td> <td>new messages</td> </tr> <tr> <td>o</td> <td>old messages</td> </tr> <tr> <td>r</td> <td>read messages</td> </tr> <tr> <td>u</td> <td>unread messages</td> </tr> </table> | d | deleted messages | n | new messages | o | old messages | r | read messages | u | unread messages |
| d              | deleted messages                                                                                                                                                                                                                                                                                               |   |                  |   |              |   |              |   |               |   |                 |
| n              | new messages                                                                                                                                                                                                                                                                                                   |   |                  |   |              |   |              |   |               |   |                 |
| o              | old messages                                                                                                                                                                                                                                                                                                   |   |                  |   |              |   |              |   |               |   |                 |
| r              | read messages                                                                                                                                                                                                                                                                                                  |   |                  |   |              |   |              |   |               |   |                 |
| u              | unread messages                                                                                                                                                                                                                                                                                                |   |                  |   |              |   |              |   |               |   |                 |

Notice that the context of the command determines whether this type of message specification makes sense.

Other arguments are usually arbitrary strings whose usage depends on the command involved. Filenames, where expected, are expanded using the normal shell conventions (see `sh(1)`). Special characters are recognized by certain commands and are documented with the commands below.

### **Sending Mail**

Recipients listed on the command line may be of three types: login names, shell commands, or alias groups. Login names may be any network address, including mixed network addressing. If mail is found to be undeliverable, an attempt is made to return it to the sender's mailbox. If the recipient name begins with a pipe symbol (`|`), the rest of the name is taken to be a shell command to pipe the message through. This provides an automatic interface with any program that reads the standard input, such as `lp(1)` for recording outgoing mail on paper. Alias groups are set by the `alias` command (see `Commands` below) or in a system startup file (for example, `$HOME/.mailrc`). Aliases are lists of recipients of any type.

### **Forwarding Mail**

To forward a specific message, include it in a message to the desired recipients with the `~f` or `~m` tilde escapes. See `Tilde Escapes` below. To forward mail automatically, add a comma-separated list of addresses for additional recipients to the `.forward` file in your home directory. This is different from the format of the `alias` command,

## mailx(1)

which takes a space-separated list instead. *Note:* Forwarding addresses must be valid, or the messages will “bounce.” You cannot, for instance, reroute your mail to a new host by forwarding it to your new address if it is not yet listed in the NIS aliases domain.

### Commands

Regular commands are of the form

[ *command* ] [ *message-list* ] [ *arguments* ]

In *input mode*, commands are recognized by the escape character, tilde (~), and lines not treated as commands are taken as input for the message. If no command is specified in *command mode*, next is assumed. The following is a complete list of mailx commands:

!*shell-command*

Escape to the shell. See SHELL in ENVIRONMENT VARIABLES.

# *comment*

NULL command (comment). Useful in mailrc files.

=

Print the current message number.

?

Prints a summary of commands.

alias *alias name* . . .

group *alias name* . . .

Declare an alias for the given names. The names are substituted when alias is used as a recipient. Useful in the mailrc file. With no arguments, the command displays the list of defined aliases.

alternates *name* . . .

Declare a list of alternate names for your login. When responding to a message, these names are removed from the list of recipients for the response. With no arguments, print the current list of alternate names. See also allnet in Internal Variables.

cd [*directory*]

chdir [*directory*]

Change directory. If *directory* is not specified, \$HOME is used.

copy [*file*]

copy [*message-list*] *file*

Copy messages to the file without marking the messages as saved. Otherwise equivalent to the save command.

Copy [*message-list*]

Save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise equivalent to the Save command.

`delete` [*message-list*]

Delete messages from the mailbox. If `autoprint` is set, the next message after the last one deleted is printed (see `Internal Variables`).

`discard` [*header-field* . . .]

`ignore` [*header-field* . . .]

Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are `Status` and `Received`. The fields are included when the message is saved, unless the `alwaysignore` variable is set. The `More`, `Page`, `Print`, and `Type` commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the `undiscard` and `unignore` commands.

`dp` [*message-list*]

`dt` [*message-list*]

Delete the specified messages from the mailbox and print the next message after the last one deleted. Roughly equivalent to a `delete` command followed by a `print` command.

`echo` *string* . . .

Echo the given strings (like `echo(1)`).

`edit` [*message-list*]

Edit the given messages. Each message is placed in a temporary file and the program named by the `EDITOR` variable is invoked to edit it (see `ENVIRONMENT VARIABLES`). Default editor is `ed(1)`.

`exit`

`xit`

Exit from `mailx`, without changing the mailbox. No messages are saved in the `mbox` (see also `quit`).

`field` [*message-list*] *header-file*

Display the value of the header field in the specified message.

`file` [*file*]

`folder` [*file*]

Quit from the current file of messages and read in the specified file. Several special characters are recognized when used as file names:

`%` the current mailbox.

`%user` the mailbox for *user*.

`#` the previous mail file.

`&` the current `mbox`.

`+file` The named file in the *folder* directory (listed in the `folder` variable).

With no arguments, print the name of the current mail file, and the number of messages and characters it contains.

## mailx(1)

### folders

Print the names of the files in the directory set by the `folder` variable (see `Internal Variables`).

### Followup [*message*]

Respond to a message, recording the response in a file whose name is derived from the author of the message. Overrides the `record` variable, if set. If the `replyall` variable is set, the actions of `Followup` and `followup` are reversed. See also the `followup`, `Save`, and `Copy` commands and `outfolder` in `Internal Variables`, and the `Starting Mail` section in `USAGE` above.

### followup [*message-list*]

Respond to the first message in the *message-list*, sending the message to the author of each message in the *message-list*. The subject line is taken from the first message and the response is recorded in a file whose name is derived from the author of the first message. If the `replyall` variable is set, the actions of `followup` and `Followup` are reversed. See also the `Followup`, `Save`, and `Copy` commands and `outfolder` in `Internal Variables`, and the `Starting Mail` section in `USAGE` above.

### from [*message-list*]

Print the header summary for the specified messages. If no messages are specified, print the header summary for the current message.

### group *alias name* . . .

### alias *alias name* . . .

Declare an alias for the given names. The names are substituted when `alias` is used as a recipient. Useful in the `mailrc` file.

### headers [*message*]

Print the page of headers which includes the message specified. The `screen` variable sets the number of headers per page (see `Internal Variables`). See also the `z` command.

### help

Print a summary of commands.

### hold [*message-list*]

### preserve [*message-list*]

Hold the specified messages in the mailbox.

### if *s* | *r* | *t*

### *mail-commands*

### else

### *mail-commands*

### endif

Conditional execution, where *s* executes following *mail-commands*, up to an `else` or `endif`, if the program is in *send* mode, *r* causes the *mail-commands* to be executed only in *receive* mode, and *t* causes the *mail-commands* to be executed only if `mailx` is being run from a terminal. Useful in the `mailrc` file.

**inc**

Incorporate messages that arrive while you are reading the system mailbox. The new messages are added to the message list in the current mail session. This command does not commit changes made during the session, and prior messages are not renumbered.

**ignore** [*header-field* ...]

**discard** [*header-field* ...]

Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are `Status` and `Cc`. All fields are included when the message is saved. The `More`, `Page`, `Print` and `Type` commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the `undiscard` and `unignore` commands.

**list**

Print all commands available. No explanation is given.

**load**

**[message] file** The specified message is replaced by the message in the named file. `file` should contain a single mail message including mail headers (as saved by the `save` command).

**mail recipient** ...

Mail a message to the specified recipients.

**Mail recipient**

Mail a message to the specified recipients, and record it in a file whose name is derived from the author of the message. Overrides the `record` variable, if set. See also the `Save` and `Copy` commands and `outfolder` in `Internal Variables`.

**mbox** [*message-list*]

Arrange for the given messages to end up in the standard mbox save file when mailx terminates normally. See `MBOX` in `ENVIRONMENT VARIABLES` for a description of this file. See also the `exit` and `quit` commands.

**more** [*message-list*]

**page** [*message-list*]

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)` or if the `bsdcompat` variable is set, the default is `more(1)`. See `ENVIRONMENT VARIABLES`. Same as the `print` and `type` commands.

**More** [*message-list*]

**Page** [*message-list*]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command. Same as the `Print` and `Type` commands.

**new** [*message-list*]

**New** [*message-list*]

**unread** [*message-list*]

## mailx(1)

### Unread

[*message-list*] Take a message list and mark each message as *not* having been read.

### next [*message*]

Go to the next message matching *message*. If *message* is not supplied, this command finds the next message that was not deleted or saved. A *message-list* may be specified, but in this case the first valid message in the list is the only one used. This is useful for jumping to the next message from a specific user, since the name would be taken as a command in the absence of a real command. See the discussion of *message-list* above for a description of possible message specifications.

### pipe [*message-list*] [*shell-command*]

| [*message-list*] [*shell-command*]

Pipe the message through the given *shell-command*. The message is treated as if it were read. If no arguments are given, the current message is piped through the command specified by the value of the `cmd` variable. If the `page` variable is set, a form feed character is inserted after each message (see `Internal Variables`).

### preserve [*message-list*]

### hold [*message-list*]

Preserve the specified messages in the mailbox.

### print [*message-list*]

### type [*message-list*]

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)` or if the `bsdcompat` variable is set, the default is `more(1)`. See `ENVIRONMENT VARIABLES`. Same as the `more` and `page` commands.

### Print [*message-list*]

### Type [*message-list*]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command. Same as the `More` and `Page` commands.

### put [*file*]

### put [*message-list*] *file*

Save the specified message in the given file. Use the same conventions as the `print` command for which header fields are ignored.

### Put [*file*]

### Put [*message-list*] *file*

Save the specified message in the given file. Overrides suppression of fields by the `ignore` command.

### quit

Exit from `mailx`, storing messages that were read in `mbox` and unread messages in the mailbox. Messages that have been explicitly saved in a file are deleted unless the `keepsave` variable is set.

reply [*message-list*]

respond [*message-list*]

replysender [*message-list*]

Send a response to the author of each message in the *message-list*. The subject line is taken from the first message. If *record* is set to a file, a copy of the reply is added to that file. If the *replyall* variable is set, the actions of Reply/Respond and reply/respond are reversed. The *replysender* command is not affected by the *replyall* variable, but sends each reply only to the sender of each message. See the Starting Mail section in USAGE above.

Reply [*message*]

Respond [*message*]

replyall [*message*]

Reply to the specified message, including all other recipients of that message. If the variable *record* is set to a file, a copy of the reply added to that file. If the *replyall* variable is set, the actions of Reply/Respond and reply/respond are reversed. The *replyall* command is not affected by the *replyall* variable, but always sends the reply to all recipients of the message. See the Starting Mail section in USAGE above.

retain

Add the list of header fields named to the *retained list*. Only the header fields in the retain list are shown on your terminal when you print a message. All other header fields are suppressed. The set of retained fields specified by the *retain* command overrides any list of ignored fields specified by the *ignore* command. The Type and Print commands can be used to print a message in its entirety. If *retain* is executed with no arguments, it lists the current set of retained fields.

Save [*message-list*]

Save the specified messages in a file whose name is derived from the author of the first message. The name of the file is taken to be the author's name with all network addressing stripped off. See also the Copy, followup, and Followup commands and outfolder in Internal Variables.

save [*file*]

save [*message-list*] *file*

Save the specified messages in the given file. The file is created if it does not exist. The file defaults to mbox. The message is deleted from the mailbox when mailx terminates unless *keepsave* is set (see also Internal Variables and the exit and quit commands).

set

set *variable*

set *variable=string*

set *variable=number*

Define a *variable*. To assign a *value* to *variable*, separate the variable name from the value by an '=' (there must be no space before or after the '='). A variable may be given a null, string, or numeric *value*. To embed SPACE characters within a *value*, enclose it in quotes.

## mailx(1)

With no arguments, set displays all defined variables and any values they might have. See *Internal Variables* for a description of all predefined mail variables.

**shell**  
Invoke an interactive shell. See also SHELL in ENVIRONMENT VARIABLES.

**size** [*message-list*]  
Print the size in characters of the specified messages.

**source** *file*  
Read commands from the given file and return to command mode.

**top** [*message-list*]  
Print the top few lines of the specified messages. If the *toplines* variable is set, it is taken as the number of lines to print (see *Internal Variables*). The default is 5.

**touch** [*message-list*]  
Touch the specified messages. If any message in *message-list* is not specifically saved in a file, it is placed in the *mbox*, or the file specified in the MBOX environment variable, upon normal termination. See *exit* and *quit*.

**Type** [*message-list*]  
**Print** [*message-list*]  
Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the *ignore* command.

**type** [*message-list*]  
**print** [*message-list*]  
Print the specified messages. If *crt* is set, the messages longer than the number of lines specified by the *crt* variable are paged through the command specified by the *PAGER* variable. The default command is *pg(1)*. See ENVIRONMENT VARIABLES.

**unalias** [*alias*] ...  
**ungroup** [*alias*] ...  
Remove the definitions of the specified aliases.

**undelete** [*message-list*]  
Restore the specified deleted messages. Will only restore messages deleted in the current mail session. If *autoprint* is set, the last message of those restored is printed (see *Internal Variables*).

**undiscard** [*header-field* ...]  
**unignore** [*header-field* ...]  
Remove the specified header fields from the list being ignored. If no header fields are specified, all header fields are removed from the list being ignored.

**unretain** [*header-field* ...]  
Remove the specified header fields from the list being retained. If no header fields are specified, all header fields are removed from the list being retained.

**unread** [*message-list*]  
**Unread** [*message-list*] Same as the *new* command.

`unset variable . . .`

Erase the specified variables. If the variable was imported from the environment (that is, an environment variable or exported shell variable), it cannot be unset from within mailx.

`version`

Print the current version and release date of the mailx utility.

`visual [message-list]`

Edit the given messages with a screen editor. Each messages is placed in a temporary file and the program named by the VISUAL variable is invoked to edit it (see ENVIRONMENT VARIABLES). Notice that the default visual editor is vi.

`write [message-list] file`

Write the given messages on the specified file, minus the header and trailing blank line. Otherwise equivalent to the save command.

`xit`

`exit`

Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

`z[+ | -]`

Scroll the header display forward or backward one screen-full. The number of headers displayed is set by the screen variable (see Internal Variables).

## Tilde Escapes

The following tilde escape commands can be used when composing mail to send. These may be entered only from *input mode*, by beginning a line with the tilde escape character (~). See escape in Internal Variables for changing this special character. The escape character can be entered as text by typing it twice.

|                                      |                                                                                                                                                                                          |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>~ !<i>shell-command</i></code> | Escape to the shell. If present, run <i>shell-command</i> .                                                                                                                              |
| <code>~.</code>                      | Simulate end of file (terminate message input).                                                                                                                                          |
| <code>~ :<i>mail-command</i></code>  |                                                                                                                                                                                          |
| <code>~_ <i>mail-command</i></code>  | Perform the command-level request. Valid only when sending a message while reading mail.                                                                                                 |
| <code>~?</code>                      | Print a summary of tilde escapes.                                                                                                                                                        |
| <code>~A</code>                      | Insert the autograph string Sign into the message (see Internal Variables).                                                                                                              |
| <code>~a</code>                      | Insert the autograph string sign into the message (see Internal Variables).                                                                                                              |
| <code>~b <i>name</i> . . .</code>    | Add the <i>names</i> to the blind carbon copy (Bcc) list. This is like the carbon copy (Cc) list, except that the names in the Bcc list are not shown in the header of the mail message. |
| <code>~c <i>name</i> . . .</code>    | Add the <i>names</i> to the carbon copy (Cc) list.                                                                                                                                       |

## mailx(1)

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ~d                         | Read in the <code>dead-letter</code> file. See <code>DEAD</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file.                                                                                                                                                                                                                                                                                                                                                                   |
| ~e                         | Invoke the editor on the partial message. See also <code>EDITOR</code> in <code>ENVIRONMENT VARIABLES</code> .                                                                                                                                                                                                                                                                                                                                                                                           |
| ~f [ <i>message-list</i> ] | Forward the specified message, or the current message being read. Valid only when sending a message while reading mail. The messages are inserted into the message without alteration (as opposed to the ~m escape).                                                                                                                                                                                                                                                                                     |
| ~F [ <i>message-list</i> ] | Forward the specified message, or the current message being read, including all header fields. Overrides the suppression of fields by the <code>ignore</code> command.                                                                                                                                                                                                                                                                                                                                   |
| ~h                         | Prompt for Subject line and <code>To</code> , <code>Cc</code> , and <code>Bcc</code> lists. If the field is displayed with an initial value, it may be edited as if you had just typed it.                                                                                                                                                                                                                                                                                                               |
| ~i <i>variable</i>         | Insert the value of the named variable into the text of the message. For example, ~A is equivalent to '~i Sign.' Environment variables set and exported in the shell are also accessible by ~i.                                                                                                                                                                                                                                                                                                          |
| ~m [ <i>message-list</i> ] | Insert the listed messages, or the current message being read into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line.                                                                                                       |
| ~M [ <i>message-list</i> ] | Insert the listed messages, or the current message being read, including the header fields, into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line. Overrides the suppression of fields by the <code>ignore</code> command. |
| ~p                         | Print the message being entered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ~q                         | Quit from input mode by simulating an interrupt. If the body of the message is not null, the partial message is saved in <code>dead-letter</code> . See <code>DEAD</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file.                                                                                                                                                                                                                                                          |
| ~R                         | Mark message for return receipt.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                    |                                                                                                                                                                                                                      |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>~r file</code>               |                                                                                                                                                                                                                      |
| <code>~&lt; file</code>            |                                                                                                                                                                                                                      |
| <code>~&lt; ! shell-command</code> | Read in the specified file. If the argument begins with an exclamation point (!), the rest of the string is taken as an arbitrary shell command and is executed, with the standard output inserted into the message. |
| <code>~s string ...</code>         | Set the subject line to <i>string</i> .                                                                                                                                                                              |
| <code>~t name ...</code>           | Add the given <i>names</i> to the To list.                                                                                                                                                                           |
| <code>~v</code>                    | Invoke a preferred screen editor on the partial message. The default visual editor is <code>vi(1)</code> . See also <code>VISUAL</code> in ENVIRONMENT VARIABLES.                                                    |
| <code>~w file</code>               | Write the message into the given file, without the header.                                                                                                                                                           |
| <code>~x</code>                    | Exit as with <code>~q</code> except the message is not saved in <code>dead-letter</code> .                                                                                                                           |
| <code>~   shell-command</code>     | Pipe the body of the message through the given <i>shell-command</i> . If the <i>shell-command</i> returns a successful exit status, the output of the command replaces the message.                                  |

**Internal Variables**

The following variables are internal variables. They may be imported from the execution environment or set using the `set` command at any time. The `unset` command may be used to erase variables.

|                               |                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>allnet</code>           | All network names whose last component (login name) match are treated as identical. This causes the <i>message-list</i> message specifications to behave similarly. Disabled by default. See also the <code>alternates</code> command and the <code>metoo</code> and <code>fuzzymatch</code> variables.                                                                |
| <code>alwaysignore</code>     | Ignore header fields with <code>ignore</code> everywhere, not just during <code>print</code> or <code>type</code> . Affects the <code>save</code> , <code>Save</code> , <code>copy</code> , <code>Copy</code> , <code>top</code> , <code>pipe</code> , and <code>write</code> commands, and the <code>~m</code> and <code>~f</code> tilde escapes. Enabled by default. |
| <code>append</code>           | Upon termination, append messages to the end of the <code>mbox</code> file instead of prepending them. Although disabled by default, <code>append</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).                                                                                                     |
| <code>appenddeadletter</code> | Append to the <code>deadletter</code> file rather than overwrite it. Although disabled by default, <code>appenddeadletter</code> is frequently set in the system startup file. See <code>Starting Mail</code> in <code>USAGE</code> above.                                                                                                                             |

## mailx(1)

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| askbcc                    | Prompt for the Bcc list after the Subject is entered if it is not specified on the command line with the -b option. Disabled by default.                                                                                                                                                                                                                                                                                                                                                         |
| askcc                     | Prompt for the Cc list after the Subject is entered if it is not specified on the command line with the -c option. Disabled by default.                                                                                                                                                                                                                                                                                                                                                          |
| asksub                    | Prompt for subject if it is not specified on the command line with the -s option. Enabled by default.                                                                                                                                                                                                                                                                                                                                                                                            |
| autoinc                   | Automatically incorporate new messages into the current session as they arrive. This has an affect similar to issuing the inc command every time the command prompt is displayed. Disabled by default, but autoinc is set in the default system startup file for mailx; it is not set for /usr/ucb/mail or /usr/ucb/Mail.                                                                                                                                                                        |
| autoprint                 | Enable automatic printing of messages after delete and undelete commands. Disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                   |
| bang                      | Enable the special-casing of exclamation points (!) in shell escape command lines as in vi(1). Disabled by default.                                                                                                                                                                                                                                                                                                                                                                              |
| bsdcompat                 | Set automatically if mailx is invoked as mail or Mail. Causes mailx to use /etc/mail/Mail.rc as the system startup file. Changes the default pager to more(1).                                                                                                                                                                                                                                                                                                                                   |
| cmd= <i>shell-command</i> | Set the default command for the pipe command. No default value.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| conv= <i>conversion</i>   | Convert uucp addresses to the specified address style, which can be either:<br><br>internet      This requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing.<br><br>optimize      Remove loops in uucp(1C) address paths (typically generated by the reply command). No rerouting is performed; mail has no knowledge of UUCP routes or connections.<br><br>Conversion is disabled by default. See also sendmail(1M) and the -U command-line option. |
| crt[= <i>number</i> ]     | Pipe messages having more than <i>number</i> lines through the command specified by the value of the PAGER                                                                                                                                                                                                                                                                                                                                                                                       |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | variable ( <code>pg(1)</code> or <code>more(1)</code> by default). If <i>number</i> is not specified, the current window size is used. Disabled by default.                                                                                                                                                                                                                                    |
| <code>debug</code>            | Enable verbose diagnostics for debugging. Messages are not delivered. Disabled by default.                                                                                                                                                                                                                                                                                                     |
| <code>dot</code>              | Take a period on a line by itself, or EOF during input from a terminal as end-of-file. Disabled by default, but <code>dot</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).                                                                                                                                                     |
| <code>fcc</code>              | By default, <code>mailx</code> will treat any address containing a slash ("/") character as a local "send to file" address. By unsetting this option, this behavior is disabled. Enabled by default.                                                                                                                                                                                           |
| <code>flipr</code>            | Reverse the effect of the <code>followup/Followup</code> and <code>reply/Reply</code> command pairs. If both <code>flipr</code> and <code>replyall</code> are set, the effect is as if neither was set.                                                                                                                                                                                        |
| <code>from</code>             | Extract the author listed in the header summary from the <code>From:</code> header instead of the UNIX <code>From</code> line. Enabled by default.                                                                                                                                                                                                                                             |
| <code>fuzzymatch</code>       | The <code>from</code> command searches for messages from the indicated sender. By default, the full sender address must be specified. By setting this option, only a sub-string of the sender address need be specified. Disabled by default.                                                                                                                                                  |
| <code>escape=c</code>         | Substitute <i>c</i> for the <code>~</code> escape character. Takes effect with next message sent.                                                                                                                                                                                                                                                                                              |
| <code>folder=directory</code> | The directory for saving standard mail files. User-specified file names beginning with a plus (+) are expanded by preceding the file name with this directory name to obtain the real file name. If <i>directory</i> does not start with a slash (/), <code>\$HOME</code> is prepended to it. There is no default for the <code>folder</code> variable. See also <code>outfolder</code> below. |
| <code>header</code>           | Enable printing of the header summary when entering <code>mailx</code> . Enabled by default.                                                                                                                                                                                                                                                                                                   |
| <code>hold</code>             | Preserve all messages that are read in the mailbox instead of putting them in the standard <code>mbox</code> save file. Disabled by default.                                                                                                                                                                                                                                                   |
| <code>ignore</code>           | Ignore interrupts while entering messages. Handy for noisy dial-up lines. Disabled by default.                                                                                                                                                                                                                                                                                                 |

## mailx(1)

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ignoreeof</code>           | Ignore end-of-file during message input. Input must be terminated by a period (.) on a line by itself or by the <code>~.</code> command. See also <code>dot</code> above. Disabled by default.                                                                                                                                                                                                             |
| <code>indentprefix=string</code> | When <code>indentprefix</code> is set, <i>string</i> is used to mark indented lines from messages included with <code>~m</code> . The default is a TAB character.                                                                                                                                                                                                                                          |
| <code>keep</code>                | When the mailbox is empty, truncate it to zero length instead of removing it. Disabled by default.                                                                                                                                                                                                                                                                                                         |
| <code>iprompt=string</code>      | The specified prompt string is displayed before each line on input is requested when sending a message.                                                                                                                                                                                                                                                                                                    |
| <code>keepsave</code>            | Keep messages that have been saved in other files in the mailbox instead of deleting them. Disabled by default.                                                                                                                                                                                                                                                                                            |
| <code>makeremote</code>          | When replying to all recipients of a message, if an address does not include a machine name, it is assumed to be relative to the sender of the message. Normally not needed when dealing with hosts that support RFC822.                                                                                                                                                                                   |
| <code>metoo</code>               | If your login appears as a recipient, do not delete it from the list. Disabled by default.                                                                                                                                                                                                                                                                                                                 |
| <code>mustbang</code>            | Force all mail addresses to be in bang format.                                                                                                                                                                                                                                                                                                                                                             |
| <code>onehop</code>              | When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag disables alteration of the recipients' addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). Disabled by default. |
| <code>outfolder</code>           | Locate the files used to record outgoing messages in the directory specified by the <code>folder</code> variable unless the path name is absolute. Disabled by default. See <code>folder</code> above and the <code>Save</code> , <code>Copy</code> , <code>followup</code> , and <code>Followup</code> commands.                                                                                          |
| <code>page</code>                | Used with the <code>pipe</code> command to insert a form feed after each message sent through the pipe. Disabled by default.                                                                                                                                                                                                                                                                               |
| <code>pipeignore</code>          | Omit ignored header when outputting to the <code>pipe</code> command. Although disabled by default, <code>pipeignore</code> is frequently set in the system startup file. See <code>Starting Mail in USAGE</code> above.                                                                                                                                                                                   |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| postmark                       | Your "real name" to be included in the From line of messages you send. By default this is derived from the comment field in your passwd(4) file entry.                                                                                                                                                                                                                                                                  |
| prompt= <i>string</i>          | Set the <i>command mode</i> prompt to <i>string</i> . Default is "? ", unless the bsdcompat variable is set, then the default is "&".                                                                                                                                                                                                                                                                                   |
| quiet                          | Refrain from printing the opening message and version when entering mailx. Disabled by default.                                                                                                                                                                                                                                                                                                                         |
| record= <i>file</i>            | Record all outgoing mail in <i>file</i> . Disabled by default. See also outfolder above.                                                                                                                                                                                                                                                                                                                                |
| replyall                       | Reverse the effect of the reply and Reply and followup and Followup commands. Although set by default, replayall is frequently unset in the system startup file. See flipr and Starting Mail in USAGE above.                                                                                                                                                                                                            |
| returnaddr= <i>string</i>      | The default sender address is that of the current user. This variable can be used to set the sender address to any arbitrary value. Set with caution.                                                                                                                                                                                                                                                                   |
| save                           | Enable saving of messages in dead-letter on interrupt or delivery error. See DEAD for a description of this file. Enabled by default.                                                                                                                                                                                                                                                                                   |
| screen= <i>number</i>          | Sets the number of lines in a screen-full of headers for the headers command. <i>number</i> must be a positive number.<br><br>The default is set according to baud rate or window size. With a baud rate less than 1200, <i>number</i> defaults to 5, if baud rate is exactly 1200, it defaults to 10. If you are in a window, <i>number</i> defaults to the default window size minus 4. Otherwise, the default is 20. |
| sendmail= <i>shell-command</i> | Alternate command for delivering messages. <i>Note:</i> In addition to the expected list of recipients, mail also passes the -i and -m, flags to the command. Since these flags are not appropriate to other commands, you may have to use a shell script that strips them from the arguments list before invoking the desired command. Default is /usr/bin/rmail.                                                      |
| sendwait                       | Wait for background mailer to finish before returning. Disabled by default.                                                                                                                                                                                                                                                                                                                                             |
| showname                       | Causes the message header display to show the sender's real name (if known) rather than their mail                                                                                                                                                                                                                                                                                                                      |

## mailx(1)

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | address. Disabled by default, but <code>showname</code> is set in the <code>/etc/mail/mailx.rc</code> system startup file for <code>mailx</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>showto</code>          | When displaying the header summary and the message is from you, print the recipient's name instead of the author's name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>sign=string</code>     | The variable inserted into the text of a message when the <code>~a</code> (autograph) command is given. No default (see also <code>~i</code> in <i>Tilde Escapes</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>Sign=string</code>     | The variable inserted into the text of a message when the <code>~A</code> command is given. No default (see also <code>~i</code> in <i>Tilde Escapes</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>toplines=number</code> | The number of lines of header to print with the <code>top</code> command. Default is 5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>verbose</code>         | Invoke <code>sendmail(1M)</code> with the <code>-v</code> flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>translate</code>       | <p>The name of a program to translate mail addresses. The program receives mail addresses as arguments. The program produces, on the standard output, lines containing the following data, in this order:</p> <ul style="list-style-type: none"><li>■ the postmark for the sender (see the <code>postmark</code> variable)</li><li>■ translated mail addresses, one per line, corresponding to the program's arguments. Each translated address will replace the corresponding address in the mail message being sent.</li><li>■ a line containing only "y" or "n". if the line contains "y" the user will be asked to confirm that the message should be sent.</li></ul> <p>The <code>translate</code> program will be invoked for each mail message to be sent. If the program exits with a non-zero exit status, or fails to produce enough output, the message is not sent.</p> |
| <b>Large File Behavior</b>   | See <code>largefile(5)</code> for the description of the behavior of <code>mailx</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>mailx</code> : <code>HOME</code> , <code>LANG</code> , <code>LC_CTYPE</code> , <code>LC_TIME</code> , <code>LC_MESSAGES</code> , <code>NLSPATH</code> , and <code>TERM</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>DEAD</code>            | The name of the file in which to save partial letters in case of untimely interrupt. Default is <code>\$HOME/dead.letter</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|            |                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EDITOR     | The command to run when the edit or ~e command is used. Default is ed(1).                                                                                                                                                          |
| LISTER     | The command (and options) to use when listing the contents of the folder directory. The default is ls(1).                                                                                                                          |
| MAIL       | The name of the initial mailbox file to read (in lieu of the standard system mailbox). The default is <code>/var/mail/username</code> .                                                                                            |
| MAILRC     | The name of the startup file. Default is <code>\$HOME/.mailrc</code> .                                                                                                                                                             |
| MAILX_HEAD | The specified string is included at the beginning of the body of each message that is sent.                                                                                                                                        |
| MAILX_TAIL | The specified string is included at the end of the body of each message that is sent.                                                                                                                                              |
| MBOX       | The name of the file to save messages which have been read. The exit command overrides this function, as does saving the message explicitly in another file. Default is <code>\$HOME/mbox</code> .                                 |
| PAGER      | The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is pg(1), or if the <code>bsdcompat</code> variable is set, the default is more(1). See Internal Variables. |
| SHELL      | The name of a preferred command interpreter. Default is sh(1).                                                                                                                                                                     |
| VISUAL     | The name of a preferred screen editor. Default is vi(1).                                                                                                                                                                           |

**EXIT STATUS** When the -e option is specified, the following exit values are returned:

- 0 Mail was found.
- >0 Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

- 0 Successful completion. Notice that this status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*.
- >0 An error occurred

**FILES**

`$HOME/.mailrc`  
personal startup file

`$HOME/mbox`  
secondary storage file

`$HOME/.Maillock`  
lock file to prevent multiple writers of system mailbox

`/etc/mail/mailx.rc`  
optional system startup file for mailx only

## mailx(1)

/etc/mail/Mail.rc  
BSD compatibility system-wide startup file for /usr/ucb/mail and /usr/ucb/Mail

/tmp/R[emqsx] \*  
temporary files

/usr/share/lib/mailx/mailx.help\*  
help message files

/var/mail/\*  
post office directory

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**SEE ALSO** `biff(1B)`, `echo(1)`, `ed(1)`, `ex(1)`, `fmt(1)`, `lp(1)`, `ls(1)`, `mail(1)`, `mail(1B)`, `mailcompat(1)`, `more(1)`, `pg(1)`, `sh(1)`, `uucp(1C)`, `vacation(1)`, `vi(1)`, `newaliases(1M)`, `sendmail(1M)`, `aliases(4)`, `passwd(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**NOTES** Where *shell-command* is shown as valid, arguments are not always allowed. Experimentation is recommended.

Internal variables imported from the execution environment cannot be unset.

The full internet addressing is not fully supported by `mailx`. The new standards need some time to settle down.

Replies do not always generate correct return addresses. Try resending the errant reply with `onehop set`.

`mailx` does not lock your record file. So, if you use a record file and send two or more messages simultaneously, lines from the messages may be interleaved in the record file.

The format for the `alias` command is a space-separated list of recipients, while the format for an alias in either the `.forward` or `/etc/aliases` is a comma-separated list.

To read mail on a workstation running Solaris 1.x when your mail server is running Solaris 2.x, first execute the `mailcompat(1)` program.

| <b>DESCRIPTION</b> | <p>The make utility executes a list of shell commands associated with each <i>target</i>, typically to create or update a file of the same name. <i>makefile</i> contains entries that describe how to bring a target up to date with respect to those on which it depends, which are called <i>dependencies</i>. Since each dependency is a target, it may have dependencies of its own. Targets, dependencies, and sub-dependencies comprise a tree structure that make traces when deciding whether or not to rebuild a <i>target</i>.</p> <p>The make utility recursively checks each <i>target</i> against its dependencies, beginning with the first target entry in <i>makefile</i> if no <i>target</i> argument is supplied on the command line. If, after processing all of its dependencies, a target file is found either to be missing, or to be older than any of its dependencies, make rebuilds it. Optionally with this version of make, a target can be treated as out-of-date when the commands used to generate it have changed since the last time the target was built.</p> <p>To build a given target, make executes the list of commands, called a <i>rule</i>. This rule may be listed explicitly in the target's makefile entry, or it may be supplied implicitly by make.</p> <p>If no <i>target</i> is specified on the command line, make uses the first target defined in <i>makefile</i>.</p> <p>If a <i>target</i> has no makefile entry, or if its entry has no rule, make attempts to derive a rule by each of the following methods, in turn, until a suitable rule is found. Each method is described under USAGE below.</p> <ul style="list-style-type: none"> <li>■ Pattern matching rules.</li> <li>■ Implicit rules, read in from a user-supplied makefile.</li> <li>■ Standard implicit rules (also known as suffix rules), typically read in from the file <code>/usr/share/lib/make/make.rules</code>.</li> <li>■ SCCS retrieval. make retrieves the most recent version from the SCCS history file (if any). See the description of the <code>.SCCS_GET</code>: special-function target for details.</li> <li>■ The rule from the <code>.DEFAULT</code>: target entry, if there is such an entry in the makefile.</li> </ul> <p>If there is no makefile entry for a <i>target</i>, if no rule can be derived for building it, and if no file by that name is present, make issues an error message and halts.</p> |
| <b>OPTIONS</b>     | The following options are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| -f <i>makefile</i>  | <p>Uses the description file <i>makefile</i>. A '-' as the <i>makefile</i> argument denotes the standard input. The contents of <i>makefile</i>, when present, override the standard set of implicit rules and predefined macros. When more than one '-f <i>makefile</i>' argument pair appears, make uses the concatenation of those files, in order of appearance.</p> <p>When no <i>makefile</i> is specified, /usr/ccs/bin/make tries the following in sequence, except when in POSIX mode (see the .POSIX Special-Function Targets in the USAGE section below):</p> <ul style="list-style-type: none"><li>■ If there is a file named <i>makefile</i> in the working directory, make uses that file. If, however, there is an SCCS history file (SCCS/s.<i>makefile</i>) which is newer, make attempts to retrieve and use the most recent version.</li><li>■ In the absence of the above file(s), if a file named <i>Makefile</i> is present in the working directory, make attempts to use it. If there is an SCCS history file (SCCS/s.<i>Makefile</i>) that is newer, make attempts to retrieve and use the most recent version.</li></ul> <p>When no <i>makefile</i> is specified, /usr/ccs/bin/make in POSIX mode and /usr/xpg4/bin/make try the following files in sequence:</p> <ul style="list-style-type: none"><li>■ ./makefile, ./Makefile</li><li>■ s.makefile, SCCS/s.makefile</li><li>■ s.Makefile, SCCS/s.Makefile</li></ul> |
| -i                  | Ignores error codes returned by commands. Equivalent to the special-function target '. IGNORE:'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -k                  | When a nonzero error status is returned by a rule, or when make cannot find a rule, abandons work on the current target, but continues with other dependency branches that do not depend on it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| -K <i>statefile</i> | Uses the state file <i>statefile</i> . A '-' as the <i>statefile</i> argument denotes the standard input. The contents of <i>statefile</i> , when present, override the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

standard set of implicit rules and predefined macros. When more than one '-k *statefile*' argument pair appears, make uses the concatenation of those files, in order of appearance. (See also .KEEP\_STATE and .KEEP\_STATE\_FILE in the Special-Function Targets section).

- n No execution mode. Prints commands, but does not execute them. Even lines beginning with an @ are printed. However, if a command line contains a reference to the \$(MAKE) macro, that line is always executed (see the discussion of MAKEFLAGS in Reading Makefiles and the Environment). When in POSIX mode, lines beginning with a "+" are executed.
- p Prints out the complete set of macro definitions and target descriptions.
- P Merely reports dependencies, rather than building them.
- q Question mode. make returns a zero or nonzero status code depending on whether or not the target file is up to date. When in POSIX mode, lines beginning with a "+" are executed.
- r Does not read in the default makefile /usr/share/lib/make/make.rules.
- s Silent mode. Does not print command lines before executing them. Equivalent to the special-function target .SILENT:.
- S Undoes the effect of the -k option. Stops processing when a non-zero exit status is returned by a command.
- t Touches the target files (bringing them up to date) rather than performing their rules. *Warning:* This can be *dangerous* when files are maintained by more than one person. When the .KEEP\_STATE: target appears in the makefile, this option updates the state file just as if the rules had been performed. When in POSIX mode, lines beginning with a "+" are executed.
- V Puts make into SysV mode. Refer to sysv-make(1) for respective details.

**OPERANDS** The following operands are supported:

- target* Target names, as defined in USAGE.
- macro=value* Macro definition. This definition overrides any regular definition for the specified macro within the makefile itself, or in the environment. However, this definition can still be overridden by conditional macro assignments.

**USAGE** The usage of make is described below:

make(1S)

### Reading Makefiles and the Environment

When `make` first starts, it reads the `MAKEFLAGS` environment variable to obtain any of the following options specified present in its value: `-d`, `-D`, `-e`, `-i`, `-k`, `-n`, `-p`, `-q`, `-r`, `-s`, `-S`, or `-t`. Due to the implementation of POSIX.2 (see `POSIX.2(5)`), the `MAKEFLAGS` values will contain a leading `'-` character. The `make` utility then reads the command line for additional options, which also take effect.

Next, `make` reads in a default makefile that typically contains predefined macro definitions, target entries for implicit rules, and additional rules, such as the rule for retrieving SCCS files. If present, `make` uses the file `make.rules` in the current directory; otherwise it reads the file `/usr/share/lib/make/make.rules`, which contains the standard definitions and rules. Use the directive:

```
include /usr/share/lib/make/make.rules
```

in your local `make.rules` file to include them.

Next, `make` imports variables from the environment (unless the `-e` option is in effect), and treats them as defined macros. Because `make` uses the most recent definition it encounters, a macro definition in the makefile normally overrides an environment variable of the same name. When `-e` is in effect, however, environment variables are read in *after* all makefiles have been read. In that case, the environment variables take precedence over definitions in the makefile.

Next, `make` reads any makefiles you specify with `-f`, or one of `makefile` or `Makefile` as described above and then the state file, in the local directory if it exists. If the makefile contains a `.KEEP_STATE_FILE` target, then it reads the state file that follows the target. Refer to special target `.KEEP_STATE_FILE` for details.

Next (after reading the environment if `-e` is in effect), `make` reads in any macro definitions supplied as command line arguments. These override macro definitions in the makefile and the environment both, but only for the `make` command itself.

`make` exports environment variables, using the most recently defined value. Macro definitions supplied on the command line are not normally exported, unless the macro is also an environment variable.

`make` does not export macros defined in the makefile. If an environment variable is set, and a macro with the same name is defined on the command line, `make` exports its value as defined on the command line. Unless `-e` is in effect, macro definitions within the makefile take precedence over those imported from the environment.

The macros `MAKEFLAGS`, `MAKE`, `SHELL`, `HOST_ARCH`, `HOST_MACH`, and `TARGET_MACH` are special cases. See Special-Purpose Macros below for details.

### Makefile Target Entries

A target entry has the following format:

```
target [: | ::] [dependency] . . . [; command] . . .
 [command]
 . . .
```

The first line contains the name of a target, or a space-separated list of target names, terminated with a colon or double colon. If a list of targets is given, this is equivalent to having a separate entry of the same form for each target. The colon(s) may be followed by a *dependency*, or a dependency list. `make` checks this list before building the target. The dependency list may be terminated with a semicolon (;), which in turn can be followed by a single Bourne shell command. Subsequent lines in the target entry begin with a TAB and contain Bourne shell commands. These commands comprise the rule for building the target.

Shell commands may be continued across input lines by escaping the NEWLINE with a backslash (\). The continuing line must also start with a TAB.

To rebuild a target, `make` expands macros, strips off initial TAB characters and either executes the command directly (if it contains no shell metacharacters), or passes each command line to a Bourne shell for execution.

The first *non-empty* line that does not begin with a TAB or '#' begins another target or macro definition.

|                                 |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Global</i>                   | #                       | Start a comment. The comment ends at the next NEWLINE. If the '#' follows the TAB in a command line, that line is passed to the shell (which also treats '#' as the start of a comment).                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                 | include <i>filename</i> | If the word <code>include</code> appears as the first seven letters of a line and is followed by a SPACE or TAB, the string that follows is taken as a filename to interpolate at that line. <code>include</code> files can be nested to a depth of no more than about 16. If <i>filename</i> is a macro reference, it is expanded.                                                                                                                                                                                                                                                                               |
| <i>Targets and Dependencies</i> | :                       | Target list terminator. Words following the colon are added to the dependency list for the target or targets. If a target is named in more than one colon-terminated target entry, the dependencies for all its entries are added to form that target's complete dependency list.                                                                                                                                                                                                                                                                                                                                 |
|                                 | ::                      | Target terminator for alternate dependencies. When used in place of a ':' the double-colon allows a target to be checked and updated with respect to alternate dependency lists. When the target is out-of-date with respect to dependencies listed in the first alternate, it is built according to the rule for that entry. When out-of-date with respect to dependencies in another alternate, it is built according the rule in that other entry. Implicit rules do not apply to double-colon targets; you must supply a rule for each entry. If no dependencies are specified, the rule is always performed. |

## make(1S)

|        |                                          |                                                                                                                                                                                                                                                                                                                                                                               |
|--------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | <i>target</i> [+ <i>target</i> . . . ] : | Target group. The rule in the target entry builds all the indicated targets as a group. It is normally performed only once per make run, but is checked for command dependencies every time a target in the group is encountered in the dependency scan.                                                                                                                      |
|        | %                                        | Pattern matching wild card metacharacter. Like the '*' shell wild card, '%' matches any string of zero or more characters in a target name or dependency, in the target portion of a conditional macro definition, or within a pattern replacement macro reference. Notice that only one '%' can appear in a target, dependency-name, or pattern-replacement macro reference. |
|        | ./ <i>pathname</i>                       | make ignores the leading './' characters from targets with names given as pathnames relative to "dot," the working directory.                                                                                                                                                                                                                                                 |
| Macros | =                                        | Macro definition. The word to the left of this character is the macro name; words to the right comprise its value. Leading and trailing white space characters are stripped from the value. A word break following the = is implied.                                                                                                                                          |
|        | \$                                       | Macro reference. The following character, or the parenthesized or bracketed string, is interpreted as a macro reference: make expands the reference (including the \$) by replacing it with the macro's value.                                                                                                                                                                |
|        | ( )<br>{ }                               | Macro-reference name delimiters. A parenthesized or bracketed word appended to a \$ is taken as the name of the macro being referred to. Without the delimiters, make recognizes only the first character as the macro name.                                                                                                                                                  |
|        | \$\$                                     | A reference to the dollar-sign macro, the value of which is the character '\$'. Used to pass variable expressions beginning with \$ to the shell, to refer to environment variables which are expanded by the shell, or to delay processing of dynamic macros within the dependency list of a target, until that target is actually processed.                                |
|        | \\$                                      | Escaped dollar-sign character. Interpreted as a literal dollar sign within a rule.                                                                                                                                                                                                                                                                                            |
|        | +=                                       | When used in place of '=', appends a string to a macro definition (must be surrounded by white space, unlike '=').                                                                                                                                                                                                                                                            |
|        | :=                                       | Conditional macro assignment. When preceded by a list of targets with explicit target entries, the macro definition that follows takes effect when processing only those targets, and their dependencies.                                                                                                                                                                     |
|        | :sh =                                    | Define the value of a macro to be the output of a command (see Command Substitutions below).                                                                                                                                                                                                                                                                                  |

|              |     |                                                                                                                                                                                                                                                                                                                                          |
|--------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Rules</i> | :sh | In a macro reference, execute the command stored in the macro, and replace the reference with the output of that command (see <code>Command Substitutions</code> below).                                                                                                                                                                 |
|              | +   | make will always execute the commands preceded by a "+", even when -n is specified.                                                                                                                                                                                                                                                      |
|              | -   | make ignores any nonzero error code returned by a command line for which the first non-TAB character is a '-'. This character is not passed to the shell as part of the command line. make normally terminates when a command returns nonzero status, unless the -i or -k options, or the .IGNORE: special-function target is in effect. |
|              | @   | If the first non-TAB character is a @, make does not print the command line before executing it. This character is not passed to the shell.                                                                                                                                                                                              |
|              | ?   | Escape command-dependency checking. Command lines starting with this character are not subject to command dependency checking.                                                                                                                                                                                                           |
|              | !   | Force command-dependency checking. Command-dependency checking is applied to command lines for which it would otherwise be suppressed. This checking is normally suppressed for lines that contain references to the '?' dynamic macro (for example, '\$?').                                                                             |

When any combination of '+', '-', '@', '?', or '!' appear as the first characters after the TAB, all that are present apply. None are passed to the shell.

### Special-Function Targets

When incorporated in a makefile, the following target names perform special-functions:

|            |                                                                                                                                                                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .DEFAULT : | If it has an entry in the makefile, the rule for this target is used to process a target when there is no other entry for it, no rule for building it, and no SCCS history file from which to retrieve a current version. make ignores any dependencies for this target. |
| .DONE :    | If defined in the makefile, make processes this target and its dependencies after all other targets are built. This target is also performed when make halts with an error, unless the .FAILED target is defined.                                                        |
| .FAILED :  | This target, along with its dependencies, is performed instead of .DONE when defined in the makefile and make halts with an error.                                                                                                                                       |

## make(1S)

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>.GET_POSIX:</code>       | This target contains the rule for retrieving the current version of an SCCS file from its history file in the current working directory. <code>make</code> uses this rule when it is running in POSIX mode.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>.IGNORE:</code>          | Ignore errors. When this target appears in the makefile, <code>make</code> ignores non-zero error codes returned from commands. When used in POSIX mode, <code>.IGNORE</code> could be followed by target names only, for which the errors will be ignored.                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>.INIT:</code>            | If defined in the makefile, this target and its dependencies are built before any other targets are processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>.KEEP_STATE:</code>      | If this target is in effect, <code>make</code> updates the state file, <code>.make.state</code> , in the current directory. This target also activates command dependencies, and hidden dependency checks. If either the <code>.KEEP_STATE:</code> target appears in the makefile, or the environment variable <code>KEEP_STATE</code> is set (" <code>setenv KEEP_STATE</code> "), <code>make</code> will rebuild everything in order to collect dependency information, even if all the targets were up to date due to previous <code>make</code> runs. See also the ENVIRONMENT VARIABLES section. This target has no effect if used in POSIX mode. |
| <code>.KEEP_STATE_FILE:</code> | This target has no effect if used in POSIX mode. This target implies <code>.KEEP_STATE</code> . If the target is followed by a filename, <code>make</code> uses it as the state file. If the target is followed by a directory name, <code>make</code> looks for a <code>.make.state</code> file in that directory. If the target is not followed by any name, <code>make</code> looks for <code>.make.state</code> file in the current working directory.                                                                                                                                                                                             |
| <code>.MAKE_VERSION:</code>    | A target-entry of the form:<br><br><code>.MAKE_VERSION: VERSION-number</code><br><br>enables version checking. If the version of <code>make</code> differs from the version indicated by a string like " <code>VERSION-1.0</code> ", <code>make</code> issues a warning message.                                                                                                                                                                                                                                                                                                                                                                       |
| <code>.NO_PARALLEL:</code>     | Currently, this target has no effect, it is, however, reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <code>.POSIX:</code>           | This target enables POSIX mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>.PRECIOUS:</code>        | List of files not to delete. <code>make</code> does not remove any of the files listed as dependencies for this target when                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

interrupted. `make` normally removes the current target when it receives an interrupt. When used in POSIX mode, if the target is not followed by a list of files, all the file are assumed precious.

|                               |                                                                                                                                                                                                                                  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>.SCCS_GET:</code>       | This target contains the rule for retrieving the current version of an SCCS file from its history file. To suppress automatic retrieval, add an entry for this target with an empty rule to your makefile.                       |
| <code>.SCCS_GET_POSIX:</code> | This target contains the rule for retrieving the current version of an SCCS file from its history file. <code>make</code> uses this rule when it is running in POSIX mode.                                                       |
| <code>.SILENT:</code>         | Run silently. When this target appears in the makefile, <code>make</code> does not echo commands before executing them. When used in POSIX mode, it could be followed by target names, and only those will be executed silently. |
| <code>.SUFFIXES:</code>       | The suffixes list for selecting implicit rules (see The Suffixes List).                                                                                                                                                          |
| <code>.WAIT:</code>           | Currently of no effect, but reserved for future use.                                                                                                                                                                             |

#### Clearing Special Targets

In this version of `make`, you can clear the definition of the following special targets by supplying entries for them with no dependencies and no rule:

`.DEFAULT`, `.SCCS_GET`, and `.SUFFIXES`

#### Command Dependencies

When the `.KEEP_STATE:` target is effective, `make` checks the command for building a target against the state file. If the command has changed since the last `make` run, `make` rebuilds the target.

#### Hidden Dependencies

When the `.KEEP_STATE:` target is effective, `make` reads reports from `cpp(1)` and other compilation processors for any “hidden” files, such as `#include` files. If the target is out of date with respect to any of these files, `make` rebuilds it.

#### Macros

Entries of the form

*macro=value*

define macros. *macro* is the name of the macro, and *value*, which consists of all characters up to a comment character or unescaped `NEWLINE`, is the value. `make` strips both leading and trailing white space in accepting the value.

Subsequent references to the macro, of the forms: `$(name)` or `${name}` are replaced by *value*. The parentheses or brackets can be omitted in a reference to a macro with a single-character name.

Macro references can contain references to other macros, in which case nested references are expanded first.

## make(1S)

### *Suffix Replacement Macro References*

Substitutions within macros can be made as follows:

```
$(name:string1=string2)
```

where *string1* is either a suffix, or a word to be replaced in the macro definition, and *string2* is the replacement suffix or word. Words in a macro value are separated by SPACE, TAB, and escaped NEWLINE characters.

### *Pattern Replacement Macro References*

Pattern matching replacements can also be applied to macros, with a reference of the form:

```
$(name:op%os=np%ns)
```

where *op* is the existing (old) prefix and *os* is the existing (old) suffix, *np* and *ns* are the new prefix and new suffix, respectively, and the pattern matched by % (a string of zero or more characters), is carried forward from the value being replaced. For example:

```
PROGRAM=fabricate
DEBUG= $(PROGRAM:%=tmp/%-g)
```

sets the value of DEBUG to tmp/fabricate-g.

Notice that pattern replacement macro references cannot be used in the dependency list of a pattern matching rule; the % characters are not evaluated independently. Also, any number of % metacharacters can appear after the equal-sign.

### *Appending to a Macro*

Words can be appended to macro values as follows:

```
macro += word ...
```

### **Special-Purpose Macros**

When the MAKEFLAGS variable is present in the environment, *make* takes options from it, in combination with options entered on the command line. *make* retains this combined value as the MAKEFLAGS macro, and exports it automatically to each command or shell it invokes.

Notice that flags passed by way of MAKEFLAGS are only displayed when the -d, or -dd options are in effect.

The MAKE macro is another special case. It has the value *make* by default, and temporarily overrides the -n option for any line in which it is referred to. This allows nested invocations of *make* written as:

```
$(MAKE) . . .
```

to run recursively, with the -n flag in effect for all commands but *make*. This lets you use 'make -n' to test an entire hierarchy of makefiles.

For compatibility with the 4.2 BSD *make*, the MFLAGS macro is set from the MAKEFLAGS variable by prepending a '-'. MFLAGS is not exported automatically.

The SHELL macro, when set to a single-word value such as /usr/bin/csh, indicates the name of an alternate shell to use. The default is /bin/sh. Notice that *make* executes commands that contain no shell metacharacters itself. Built-in commands,

such as `dirs` in the C shell, are not recognized unless the command line includes a metacharacter (for instance, a semicolon). This macro is neither imported from, nor exported to the environment, regardless of `-e`. To be sure it is set properly, you must define this macro within every makefile that requires it.

The syntax of the `VPATH` macro is:

```
VPATH = [pathname [: pathname] ...]
```

`VPATH` specifies a list of directories to search for the files, which are targets or dependencies, when `make` is executed. `VPATH` is also used in order to search for the include files mentioned in the particular makefile.

When processing a target or a dependency or an include directive, `make` checks the existence of the file with the same name in the current directory. If the file is found to be missing, `make` will search for this file in the list of directories presented in `VPATH` (like the `PATH` variable in the shell). Unlike the `PATH` variable, `VPATH` is used in order to search for the files with relative pathnames. When `make` attempts to apply implicit rules to the target, it also searches for the dependency files using `VPATH`.

When the file is found using `VPATH`, internal macros `$$`, `@<`, `$$?`, `$$*`, and their alternative forms (with `D` or `F` appended) are set in accordance with the name derived from `VPATH`. For instance, if the target `subdir/foo.o` is found in the directory `/aaa/bbb` using `VPATH`, then the value of the internal macro `$$` for this target will be `/aaa/bbb/subdir/foo.o`.

If a target or a dependency file is found using `VPATH`, then any occurrences of the word that is the same as the target name in the subsequent rules will be replaced with the actual name of the target derived from `VPATH`.

For example:

```
VPATH=./subdir
file.o : file.c
 cc -c file.c -o file.o
```

If `file.c` is found in `./subdir`, then the command

```
cc -c ./subdir/file.c -o file.o
```

will be executed.

The following macros are provided for use with cross-compilation:

|                        |                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>HOST_ARCH</code> | The machine architecture of the host system. By default, this is the output of the <code>arch(1)</code> command prepended with <code>'-'</code> . Under normal circumstances, this value should never be altered by the user. |
| <code>HOST_MACH</code> | The machine architecture of the host system. By default, this is the output of the <code>mach(1)</code> , prepended with <code>'-'</code> . Under normal circumstances, this value should never be altered by the user.       |

make(1S)

|                                      |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                                      | TARGET_ARCH | The machine architecture of the target system. By default, the output of <code>mach</code> , prepended with <code>'-'</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Dynamic Macros</b>                |             | <p>There are several dynamically maintained macros that are useful as abbreviations within rules. They are shown here as references; if you were to define them, <code>make</code> would simply override the definition.</p> <p><code>\$*</code> The basename of the current target, derived as if selected for use with an implicit rule.</p> <p><code>\$&lt;</code> The name of a dependency file, derived as if selected for use with an implicit rule.</p> <p><code>\$@</code> The name of the current target. This is the only dynamic macro whose value is strictly determined when used in a dependency list. (In which case it takes the form <code>'\$\$@'</code>.)</p> <p><code>\$?</code> The list of dependencies that are newer than the target. Command-dependency checking is automatically suppressed for lines that contain this macro, just as if the command had been prefixed with a <code>'?'</code>. See the description of <code>'?'</code>, under <i>Special Character Rules</i> above. You can force this check with the <code>!</code> command-line prefix.</p> <p><code>\$%</code> The name of the library member being processed. (See <i>Library Maintenance</i> below.)</p> <p>To refer to the <code>\$@</code> dynamic macro within a dependency list, precede the reference with an additional <code>'\$'</code> character (as in, <code>'\$\$@'</code>). Because <code>make</code> assigns <code>\$&lt;</code> and <code>\$*</code> as it would for implicit rules (according to the suffixes list and the directory contents), they may be unreliable when used within explicit target entries.</p> <p>These macros can be modified to apply either to the filename part, or the directory part of the strings they stand for, by adding an upper case <code>F</code> or <code>D</code>, respectively (and enclosing the resulting name in parentheses or braces). Thus, <code>'\$ (@D)'</code> refers to the directory part of the string <code>'\$@'</code>; if there is no directory part, <code>'.'</code> is assigned. <code>\$ (@F)</code> refers to the filename part.</p> |
| <b>Conditional Macro Definitions</b> |             | <p>A macro definition of the form:</p> <pre>target-list := macro = value</pre> <p>indicates that when processing any of the targets listed <i>and their dependencies</i>, <code>macro</code> is to be set to the <code>value</code> supplied. Notice that if a conditional macro is referred to in a dependency list, the <code>\$</code> must be delayed (use <code>\$\$</code> instead). Also, <code>target-list</code> may contain a <code>%</code> pattern, in which case the macro will be conditionally defined for all targets encountered that match the pattern. A pattern replacement reference can be used within the <code>value</code>.</p> <p>You can temporarily append to a macro's value with a conditional definition of the form:</p> <pre>target-list := macro += value</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Predefined Macros**

make supplies the macros shown in the table that follows for compilers and their options, host architectures, and other commands. Unless these macros are read in as environment variables, their values are not exported by make. If you run make with any of these set in the environment, it is a good idea to add commentary to the makefile to indicate what value each is expected to take. If `-r` is in effect, make does not read the default makefile (`./make.rules` or `/usr/share/lib/make/make.rules`) in which these macro definitions are supplied.

make(1S)

**Implicit Rules**

When a target has no entry in the makefile, `make` attempts to determine its class (if any) and apply the rule for that class. An implicit rule describes how to build any target of a given class, from an associated dependency file. The class of a target can be determined either by a pattern, or by a suffix; the corresponding dependency file (with the same basename) from which such a target might be built. In addition to a predefined set of implicit rules, `make` allows you to define your own, either by pattern, or by suffix.

*Pattern Matching Rules*

A target entry of the form:

```
tp%ts: dp%ds
 rule
```

is a pattern matching rule, in which *tp* is a target prefix, *ts* is a target suffix, *dp* is a dependency prefix, and *ds* is a dependency suffix (any of which may be null). The '%' stands for a basename of zero or more characters that is matched in the target, and is used to construct the name of a dependency. When `make` encounters a match in its search for an implicit rule, it uses the rule in that target entry to build the target from the dependency file. Pattern-matching implicit rules typically make use of the `$$` and `$$<` dynamic macros as placeholders for the target and dependency names. Other, regular dependencies may occur in the dependency list; however, none of the regular dependencies may contain '%'. An entry of the form:

```
tp%ts: [dependency...] dp%ds [dependency...]
 rule
```

is a valid pattern matching rule.

*Suffix Rules*

When no pattern matching rule applies, `make` checks the target name to see if it ends with a suffix in the known suffixes list. If so, `make` checks for any suffix rules, as well as a dependency file with same root and another recognized suffix, from which to build it.

The target entry for a suffix rule takes the form:

```
DsTs: rule
```

where *Ts* is the suffix of the target, *Ds* is the suffix of the dependency file, and *rule* is the rule for building a target in the class. Both *Ds* and *Ts* must appear in the suffixes list. (A suffix need not begin with a '.' to be recognized.)

A suffix rule with only one suffix describes how to build a target having a null (or no) suffix from a dependency file with the indicated suffix. For instance, the `.c` rule could be used to build an executable program named `file` from a C source file named `'file.c'`. If a target with a null suffix has an explicit dependency, `make` omits the search for a suffix rule.

| Table of Standard Implicit (Suffix) Rules for yacc Files |                                                                 |
|----------------------------------------------------------|-----------------------------------------------------------------|
| Implicit Rule Name                                       | Command Line                                                    |
|                                                          | \$(CC) \$(CFLAGS) -c y.tab.c<br>rm -f y.tab.c<br>mv y.tab.o \$@ |

make reads in the standard set of implicit rules from the file `/usr/share/lib/make/make.rules`, unless `-r` is in effect, or there is a `make.rules` file in the local directory that does not include that file.

### The Suffixes List

The suffixes list is given as the list of dependencies for the `.SUFFIXES:` special-function target. The default list is contained in the `SUFFIXES` macro (See *Table of Predefined Macros* for the standard list of suffixes). You can define additional `.SUFFIXES: targets`; a `.SUFFIXES` target with no dependencies clears the list of suffixes. Order is significant within the list; make selects a rule that corresponds to the target's suffix and the first dependency-file suffix found in the list. To place suffixes at the head of the list, clear the list and replace it with the new suffixes, followed by the default list:

```
.SUFFIXES:
.SUFFIXES: suffixes $(SUFFIXES)
```

A tilde (~) indicates that if a dependency file with the indicated suffix (minus the ~) is under SCCS its most recent version should be retrieved, if necessary, before the target is processed.

### Library Maintenance

A target name of the form:

```
lib (member ...)
```

refers to a member, or a space-separated list of members, in an `ar(1)` library.

The dependency of the library member on the corresponding file must be given as an explicit entry in the makefile. This can be handled by a pattern matching rule of the form:

```
lib (%.s) : %.s
```

where `.s` is the suffix of the member; this suffix is typically `.o` for object libraries.

A target name of the form:

```
lib ((symbol))
```

refers to the member of a randomized object library that defines the entry point named *symbol*.

## make(1S)

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Command Execution</b>       | <p>Command lines are executed one at a time, <i>each by its own process or shell</i>. Shell commands, notably <code>cd</code>, are ineffectual across an unescaped <code>NEWLINE</code> in the makefile. A line is printed (after macro expansion) just before being executed. This is suppressed if it starts with a <code>'@'</code>, if there is a <code>'SILENT:'</code> entry in the makefile, or if <code>make</code> is run with the <code>-s</code> option. Although the <code>-n</code> option specifies printing without execution, lines containing the macro <code>\$(MAKE)</code> are executed regardless, and lines containing the <code>@</code> special character are printed. The <code>-t</code> (<code>touch</code>) option updates the modification date of a file without executing any rules. This can be dangerous when sources are maintained by more than one person.</p> <p><code>make</code> invokes the shell with the <code>-e</code> (<code>exit-on-errors</code>) argument. Thus, with semicolon-separated command sequences, execution of the later commands depends on the success of the former. This behavior can be overridden by starting the command line with a <code>'-'</code>, or by writing a shell script that returns a non-zero status only as it finds appropriate.</p> |
| <b>Bourne Shell Constructs</b> | <p>To use the Bourne shell <code>if</code> control structure for branching, use a command line of the form:</p> <pre>if expression ; \<br/>then command ; \<br/>    ... ; \<br/>else command ; \<br/>    ... ; \<br/>fi</pre> <p>Although composed of several input lines, the escaped <code>NEWLINE</code> characters insure that <code>make</code> treats them all as one (shell) command line.</p> <p>To use the Bourne shell <code>for</code> control structure for loops, use a command line of the form:</p> <pre>for var in list ; \<br/>do command ; \<br/>    ... ; \<br/>done</pre> <p>To refer to a shell variable, use a double-dollar-sign (<code>\$\$</code>). This prevents expansion of the dollar-sign by <code>make</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Command Substitutions</b>   | <p>To incorporate the standard output of a shell command in a macro, use a definition of the form:</p> <pre>MACRO :sh =command</pre> <p>The command is executed only once, standard error output is discarded, and <code>NEWLINE</code> characters are replaced with <code>SPACES</code>. If the command has a non-zero exit status, <code>make</code> halts with an error.</p> <p>To capture the output of a shell command in a macro reference, use a reference of the form:</p> <pre>\$(MACRO :sh)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

where *MACRO* is the name of a macro containing a valid Bourne shell command line. In this case, the command is executed whenever the reference is evaluated. As with shell command substitutions, the reference is replaced with the standard output of the command. If the command has a non-zero exit status, *make* halts with an error.

In contrast to commands in rules, the command is not subject for macro substitution; therefore, a dollar sign (\$) need not be replaced with a double dollar sign (\$\$).

*Signals*

INT, SIGTERM, and QUIT signals received from the keyboard halt *make* and remove the target file being processed unless that target is in the dependency list for `.PRECIOUS:`.

**EXAMPLES****EXAMPLE 1** Defining dependencies

This makefile says that `pgm` depends on two files `a.o` and `b.o`, and that they in turn depend on their corresponding source files (`a.c` and `b.c`) along with a common file `incl.h`:

```
pgm: a.o b.o
 $(LINK.c) -o $@a.o b.o
a.o: incl.h a.c
 cc -c a.c
b.o: incl.h b.c
 cc -c b.c
```

**EXAMPLE 2** Using implicit rules

The following makefile uses implicit rules to express the same dependencies:

```
pgm: a.o b.o
 cc a.o b.o -o pgm
a.o b.o: incl.h
```

**ENVIRONMENT VARIABLES**

See *environ(5)* for descriptions of the following environment variables that affect the execution of *make*: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`KEEP_STATE`

This environment variable has the same effect as the `.KEEP_STATE:` special-function target. It enables command dependencies, hidden dependencies and writing of the state file.

`USE_SVR4_MAKE`

This environment variable causes *make* to invoke the generic System V version of *make* (`/usr/ccs/lib/avr4.make`). See *sysv-make(1)*.

`MAKEFLAGS`

This variable is interpreted as a character string representing a series of option characters to be used as the default options. The implementation will accept both of the following formats (but need not accept them when intermixed):

1. The characters are option letters without the leading hyphens or blank character separation used on a command line.
2. The characters are formatted in a manner similar to a portion of the `make` command line: options are preceded by hyphens and blank-character-separated. The `macro=name` macro definition operands can also be included. The difference between the contents of `MAKEFLAGS` and the command line is that the contents of the variable will not be subjected to the word expansions (see `wordexp(3C)`) associated with parsing the command line values.

When the command-line options `-f` or `-p` are used, they will take effect regardless of whether they also appear in `MAKEFLAGS`. If they otherwise appear in `MAKEFLAGS`, the result is undefined.

The `MAKEFLAGS` variable will be accessed from the environment before the makefile is read. At that time, all of the options (except `-f` and `-p`) and command-line macros not already included in `MAKEFLAGS` are added to the `MAKEFLAGS` macro. The `MAKEFLAGS` macro will be passed into the environment as an environment variable for all child processes. If the `MAKEFLAGS` macro is subsequently set by the makefile, it replaces the `MAKEFLAGS` variable currently found in the environment.

#### PROJECTDIR

Provides a directory to be used to search for SCCS files not found in the current directory. In all of the following cases, the search for SCCS files is made in the directory `SCCS` in the identified directory. If the value of `PROJECTDIR` begins with a slash, it shall be considered an absolute pathname. Otherwise, the value of `PROJECTDIR` is treated as a user name and that user's initial working directory shall be examined for a subdirectory `src` or `source`. If such a directory is found, it shall be used. Otherwise, the value is used as a relative pathname.

If `PROJECTDIR` is not set or has a null value, the search for SCCS files shall be made in the directory `SCCS` in the current directory. The setting of `PROJECTDIR` affects all files listed in the remainder of this utility description for files with a component named `SCCS`.

**EXIT STATUS** When the `-q` option is specified, the make utility will exit with one of the following values:

0 Successful completion.  
 1 The target was not up-to-date.  
 >1 An error occurred.

When the `-q` option is not specified, the make utility will exit with one of the following values:

0 Successful completion  
 >0 An error occurred

**FILES**

makefile  
 Makefile  
     current version(s) of make description file

s.makefile  
 s.Makefile  
     SCCS history files for the above makefile(s) in the current directory

SCCS/s.makefile  
 SCCS/s.Makefile  
     SCCS history files for the above makefile(s)

make.rules  
     default file for user-defined targets, macros, and implicit rules

/usr/share/lib/make/make.rules  
     makefile for standard implicit rules and macros (not read if `make.rules` is)

.make.state  
     state file in the local directory

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

`/usr/ccs/bin/make`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWspot        |

`/usr/xpg4/bin/make`

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4t       |
| Interface Stability | Standard        |

**SEE ALSO** `ar(1)`, `arch(1)`, `cd(1)`, `cpp(1)`, `lex(1)`, `mach(1)`, `sccs-get(1)`, `sh(1)`, `sysV-make(1)`, `yacc(1)`, `wordexp(3C)`, `passwd(4)`, `attributes(5)`, `environ(5)`, `POSIX.2(5)`, `standards(5)`

**DIAGNOSTICS**

Don't know how to make target '*target*'

There is no makefile entry for *target*, and none of make's implicit rules apply (there is no dependency file with a suffix in the suffixes list, or the target's suffix is not in the list).

\*\*\* *target* removed.

make was interrupted while building *target*. Rather than leaving a partially-completed version that is newer than its dependencies, make removes the file named *target*.

\*\*\* *target* not removed.

make was interrupted while building *target* and *target* was not present in the directory.

\*\*\* *target* could not be removed, *reason*

make was interrupted while building *target*, which was not removed for the indicated reason.

Read of include file '*file*' failed

The makefile indicated in an include directive was not found, or was inaccessible.

Loop detected when expanding macro value '*macro*'

A reference to the macro being defined was found in the definition.

Could not write state file '*file*'

You used the .KEEP\_STATE: target, but do not have write permission on the state file.

\*\*\* Error code *n*

The previous shell command returned a nonzero error code.

\*\*\* *signal message*

The previous shell command was aborted due to a signal. If '- core dumped' appears after the message, a core file was created.

Conditional macro conflict encountered

Displayed only when -d is in effect, this message indicates that two or more parallel targets currently being processed depend on a target which is built differently for each by virtue of conditional macros. Since the target cannot simultaneously satisfy both dependency relationships, it is conflicted.

**BUGS**

Some commands return nonzero status inappropriately; to overcome this difficulty, prefix the offending command line in the rule with a '-'

Filenames with the characters '=', ':', or '@', do not work.

You cannot build *file.o* from *lib(file.o)*.

Options supplied by MAKEFLAGS should be reported for nested make commands. Use the -d option to find out what options the nested command picks up from MAKEFLAGS.

This version of make is incompatible in certain respects with previous versions:

- The `-d` option output is much briefer in this version. `-dd` now produces the equivalent voluminous output.
- make attempts to derive values for the dynamic macros `'$*'`, `'$<'`, and `'$?'`, while processing explicit targets. It uses the same method as for implicit rules; in some cases this can lead either to unexpected values, or to an empty value being assigned. (Actually, this was true for earlier versions as well, even though the documentation stated otherwise.)
- make no longer searches for SCCS history "(s)" files.
- Suffix replacement in macro references are now applied after the macro is expanded.

There is no guarantee that makefiles created for this version of make will work with earlier versions.

If there is no `make.rules` file in the current directory, and the file `/usr/share/lib/make/make.rules` is missing, make stops before processing any targets. To force make to run anyway, create an empty `make.rules` file in the current directory.

Once a dependency is made, make assumes the dependency file is present for the remainder of the run. If a rule subsequently removes that file and future targets depend on its existence, unexpected errors may result.

When hidden dependency checking is in effect, the `$?` macro's value includes the names of hidden dependencies. This can lead to improper filename arguments to commands when `$?` is used in a rule.

Pattern replacement macro references cannot be used in the dependency list of a pattern matching rule.

Unlike previous versions, this version of make strips a leading `'./'` from the value of the `'$@'` dynamic macro.

With automatic SCCS retrieval, this version of make does not support tilde suffix rules.

The only dynamic macro whose value is strictly determined when used in a dependency list is `$@` (takes the form `'$$@'`).

make invokes the shell with the `-e` argument. This cannot be inferred from the syntax of the rule alone.

## man(1)

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>DESCRIPTION</b>              | The man command displays information from the reference manuals. It displays complete manual pages that you select by <i>name</i> , or one-line summaries selected either by <i>keyword</i> (-k), or by the name of an associated file (-f). If no manual page is located, man prints an error message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Source Format</b>            | Reference Manual pages are marked up with either nroff (see nroff(1)) or SGML (Standard Generalized Markup Language) tags (see sgm1(5)). The man command recognizes the type of markup and processes the file accordingly. The various source files are kept in separate directories depending on the type of markup.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Location of Manual Pages</b> | The online Reference Manual page directories are conventionally located in /usr/share/man. The nroff sources are located in the /usr/share/man/man* directories. The SGML sources are located in the /usr/share/man/sman* directories. Each directory corresponds to a section of the manual. Since these directories are optionally installed, they may not reside on your host. You may have to mount /usr/share/man from a host on which they do reside.<br><br>If there are preformatted, up-to-date versions in the corresponding cat* or fmt* directories, man simply displays or prints those versions. If the preformatted version of interest is out of date or missing, man reformats it prior to display and will store the preformatted version if cat* or fmt* is writable. The windex database is not updated. See catman(1M). If directories for the preformatted versions are not provided, man reformats a page whenever it is requested. man uses a temporary file to store the formatted text during display.<br><br>If the standard output is not a terminal, or if the '-' flag is given, man pipes its output through cat(1). Otherwise, man pipes its output through more(1) to handle paging and underlining on the screen. |
| <b>OPTIONS</b>                  | The following options are supported:<br><br>-a Shows all manual pages matching <i>name</i> within the MANPATH search path. Manual pages are displayed in the order found.<br><br>-d Debugs. Displays what a section-specifier evaluates to, method used for searching, and paths searched by man.<br><br>-f <i>file</i> ... man attempts to locate manual pages related to any of the given <i>files</i> . It strips the leading path name components from each <i>file</i> , and then prints one-line summaries containing the resulting basename or names. This option also uses the windex database.<br><br>-F Forces man to search all directories specified by MANPATH or the man.cf file, rather than using the windex lookup database. This                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

option is useful if the database is not up to date and it has been made the default behavior of the `man` command. The option therefore does not have to be invoked and is documented here for reference only.

- k *keyword* ... Prints out one-line summaries from the `windex` database (table of contents) that contain any of the given *keywords*. The `windex` database is created using `catman(1M)`.
- l Lists all manual pages found matching *name* within the search path.
- M *path* Specifies an alternate search path for manual pages. *path* is a colon-separated list of directories that contain manual page directory subtrees. For example, if *path* is `/usr/share/man:/usr/local/man`, `man` searches for *name* in the standard location, and then `/usr/local/man`. When used with the `-k` or `-f` options, the `-M` option must appear first. Each directory in the *path* is assumed to contain subdirectories of the form `man*` or `sman*`, one for each section. This option overrides the `MANPATH` environment variable.
- r Reformats the manual page, but does not display it. This replaces the `man -t name` combination.
- s *section* ... Specifies sections of the manual for `man` to search. The directories searched for *name* are limited to those specified by *section*. *section* can be a numerical digit, perhaps followed by one or more letters to match the desired section of the manual, for example, `"3libcB"`. Also, *section* can be a word, for example, `local`, `new`, `old`, `public`. *section* can also be a letter. To specify multiple sections, separate each section with a comma. This option overrides the `MANPATH` environment variable and the `man.cf` file. See `Search Path` below for an explanation of how `man` conducts its search.
- t `man` arranges for the specified manual pages to be `troffed` to a suitable raster output device (see `troff(1)`). If both the `-` and `-t` flags are given, `man` updates the `troffed` versions of each named *name* (if necessary), but does not display them.
- T *macro-package* Formats manual pages using *macro-package* rather than the standard `-man` macros defined in `/usr/share/lib/tmac/an`. See `Search Path` under `USAGE` for a complete explanation of the default search path order.

**OPERANDS** The following operand is supported:

*name* A keyword or the name of a standard utility.

**USAGE** The usage of `man` is described below:

man(1)

**Manual Page Sections**

Entries in the reference manuals are organized into *sections*. A section name consists of a major section name, typically a single digit, optionally followed by a subsection name, typically one or more letters. An unadorned major section name, for example, "9", does not act as an abbreviation for the subsections of that name, such as "9e", "9f", or "9s". That is, each subsection must be searched separately by `man -s`. Each section contains descriptions apropos to a particular reference category, with subsections refining these distinctions. See the `intro` manual pages for an explanation of the classification used in this release.

**Search Path**

Before searching for a given *name*, `man` constructs a list of candidate directories and sections. `man` searches for *name* in the directories specified by the `MANPATH` environment variable. If this variable is not set, `/usr/share/man` is searched by default.

Within the manual page directories, `man` confines its search to the sections specified in the following order:

- *sections* specified on the command line with the `-s` option
- *sections* embedded in the `MANPATH` environment variable
- *sections* specified in the `man.cf` file for each directory specified in the `MANPATH` environment variable

If none of the above exist, `man` searches each directory in the manual page path, and displays the first matching manual page found.

The `man.cf` file has the following format:

```
MANSECTS=section [,section] . . .
```

Lines beginning with '#' and blank lines are considered comments, and are ignored. Each directory specified in `MANPATH` can contain a manual page configuration file, specifying the default search order for that directory.

**Formatting Manual Pages**

Manual pages are marked up in `nroff(1)` or `sgml(5)`. `Nroff` manual pages are processed by `nroff(1)` or `troff(1)` with the `-man` macro package. Please refer to `man(5)` for information on macro usage. `SGML`—tagged manual pages are processed by an `SGML` parser and passed to the formatter.

**Preprocessing Nroff Manual Pages**

When formatting an `nroff` manual page, `man` examines the first line to determine whether it requires special processing. If the first line is a string of the form:

```
'\ " X
```

where *X* is separated from the '"' by a single `SPACE` and consists of any combination of characters in the following list, `man` pipes its input to `troff(1)` or `nroff(1)` through the corresponding preprocessors.

```
e eqn(1), or neqn for nroff
r refer(1)
```

|                                                      |                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                                      | v                                  | vgrind(1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                                      |                                    | If <code>eqn</code> or <code>neqn</code> is invoked, it will automatically read the file <code>/usr/pub/eqnchar</code> (see <code>eqnchar(5)</code> ). If <code>nroff(1)</code> is invoked, <code>col(1)</code> is automatically used.                                                                                                                                                                                                                                                                                                                           |
| <b>Referring to Other<br/>nroff Manual<br/>Pages</b> |                                    | If the first line of the <code>nroff</code> manual page is a reference to another manual page entry fitting the pattern:<br><br><code>.so man*/sourcefile</code><br><br><code>man</code> processes the indicated file in place of the current one. The reference must be expressed as a path name relative to the root of the manual page directory subtree.<br><br>When the second or any subsequent line starts with <code>.so</code> , <code>man</code> ignores it; <code>troff(1)</code> or <code>nroff(1)</code> processes the request in the usual manner. |
| <b>Processing SGML<br/>Manual Pages</b>              |                                    | Manual pages are identified as being marked up in SGML by the presence of the string <code>&lt;!DOCTYPE</code> . If the file also contains the string <code>SHADOW_PAGE</code> , the file refers to another manual page for the content. The reference is made with a file entity reference to the manual page that contains the text. This is similar to the <code>.so</code> mechanism used in the <code>nroff</code> formatted man pages.                                                                                                                     |
| <b>ENVIRONMENT<br/>VARIABLES</b>                     |                                    | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>man</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                      |
|                                                      | <code>MANPATH</code>               | A colon-separated list of directories; each directory can be followed by a comma-separated list of sections. If set, its value overrides <code>/usr/share/man</code> as the default directory search path, and the <code>man.cf</code> file as the default section search path. The <code>-M</code> and <code>-s</code> flags, in turn, override these values.)                                                                                                                                                                                                  |
|                                                      | <code>PAGER</code>                 | A program to use for interactively delivering <code>man</code> 's output to the screen. If not set, <code>'more -s'</code> is used. See <code>more(1)</code> .                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                      | <code>TCAT</code>                  | The name of the program to use to display <code>troffed</code> manual pages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                                      | <code>TROFF</code>                 | The name of the formatter to use when the <code>-t</code> flag is given. If not set, <code>troff(1)</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EXIT STATUS</b>                                   |                                    | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE     |
|---------------------|---------------------|
| Availability        | SUNWdoc             |
| CSI                 | Enabled (see NOTES) |
| Interface Stability | Standard            |

**SEE ALSO** `apropos(1)`, `cat(1)`, `col(1)`, `eqn(1)`, `more(1)`, `nroff(1)`, `refer(1)`, `tbl(1)`, `troff(1)`, `vgrind(1)`, `whatis(1)`, `catman(1M)`, `attributes(5)`, `environ(5)`, `eqnchar(5)`, `man(5)`, `sgml(5)`, `standards(5)`

**NOTES** The `-f` and `-k` options use the `windex` database, which is created by `catman(1M)`.

The `man` command is CSI-capable. However, some utilities invoked by the `man` command, namely, `troff`, `eqn`, `neqn`, `refer`, `tbl`, and `vgrind`, are not verified to be CSI-capable. Because of this, the `man` command with the `-t` option may not handle non-EUC data. Also, using the `man` command to display man pages that require special processing through `eqn`, `neqn`, `refer`, `tbl`, or `vgrind` may not be CSI-capable.

**BUGS** The manual is supposed to be reproducible either on a phototypesetter or on an ASCII terminal. However, on a terminal some information (indicated by font changes, for instance) is lost.

Some dumb terminals cannot process the vertical motions produced by the `e` (see `eqn(1)`) preprocessing flag. To prevent garbled output on these terminals, when you use `e`, also use `t`, to invoke `col(1)` implicitly. This workaround has the disadvantage of eliminating superscripts and subscripts, even on those terminals that can display them. Control-q will clear a terminal that gets confused by `eqn(1)` output.

mconnect(1)

**NAME** mconnect – connect to SMTP mail server socket

**SYNOPSIS** **mconnect** [-p *port*] [-r] [*hostname*]

**DESCRIPTION** The `mconnect` utility opens a connection to the mail server on a given host, so that it can be tested independently of all other mail software. If no host is given, the connection is made to the local host. Servers expect to speak the Simple Mail Transfer Protocol (SMTP) on this connection. Exit by typing the `quit` command. Typing `EOF` sends an end of file to the server. An interrupt closes the connection immediately and exits.

**OPTIONS** The following options are supported:

-p *port* Specify the port number instead of the default SMTP port (number 25) as the next argument.

-r "Raw" mode: disable the default line buffering and input handling. This produces an effect similar to `telnet(1)` to port number 25.

**OPERANDS** The following operand is supported:

*hostname* The name of a given host.

**USAGE** The `mconnect` command is IPv6-enabled. See `ip6(7P)`.

**FILES** `/etc/mail/sendmail.hf` help file for SMTP commands

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>DESCRIPTION</b> | <p>The <code>mcs</code> command is used to manipulate a section, by default the <code>.comment</code> section, in an ELF object file. It is used to add to, delete, print, and compress the contents of a section in an ELF object file, and print only the contents of a section in a COFF object file. <code>mcs</code> cannot add, delete, or compress the contents of a section that is contained within a segment.</p> <p>If the input file is an archive (see <code>ar(3HEAD)</code>), the archive is treated as a set of individual files. For example, if the <code>-a</code> option is specified, the <code>string</code> is appended to the comment section of each ELF object file in the archive; if the archive member is not an ELF object file, then it is left unchanged.</p> <p><code>mcs</code> must be given one or more of the options described below. It applies, in order, each of the specified options to each file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-a <i>string</i></code>      Appends <i>string</i> to the comment section of the ELF object files. If <i>string</i> contains embedded blanks, it must be enclosed in quotation marks.</li> <li><code>-c</code>                Compresses the contents of the comment section of the ELF object files. All duplicate entries are removed. The ordering of the remaining entries is not disturbed.</li> <li><code>-d</code>                Deletes the contents of the comment section from the ELF object files. The section header for the comment section is also removed.</li> <li><code>-n <i>name</i></code>        Specifies the name of the comment section to access if other than <code>.comment</code>. By default, <code>mcs</code> deals with the section named <code>.comment</code>. This option can be used to specify another section. <code>mcs</code> can take multiple <code>-n</code> options to allow for specification of multiple section comments.</li> <li><code>-p</code>                Prints the contents of the comment section on the standard output. Each section printed is tagged by the name of the file from which it was extracted, using the format <code>file [member_name] :</code> for archive files and <code>file:</code> for other files.</li> <li><code>-V</code>                Prints on standard error the version number of <code>mcs</code>.</li> </ul> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Printing a file's comment section</p> <p>The following entry</p> <pre>example% /usr/ccs/bin/mcs -p elf.file prints the comment section of the file elf.file.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

mcs(1)

**EXAMPLE 2** Appending a string to a comment section

The following entry

```
example% /usr/ccs/bin/mcs -a xyz elf.fileappends string xyz to elf.file's
comment section.
```

**FILES** /tmp/mcs\* temporary files

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

**SEE ALSO** `ar(1)`, `as(1)`, `ld(1)`, `elf(3ELF)`, `tmpnam(3C)`, `a.out(4)`, `ar(3HEAD)`, `attributes(5)`

**NOTES** When `mcs` deletes a section using the `-d` option, it tries to bind together sections of type `SHT_REL` and target sections pointed to by the `sh_info` section header field. If one is to be deleted, `mcs` attempts to delete the other of the pair.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>NAME</b>         | <code>mdb</code> – modular debugger                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>     | <pre><code>mdb [-fkmuwyAFMS] [<math>\pm</math>o option] [-p pid] [-s distance] [-I path] [-L path]       [-P prompt] [-R root] [-V dis-version] [object [core]   core         suffix]</code></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Introduction</b> | <p>The <code>mdb</code> utility is an extensible utility for low-level debugging and editing of the live operating system, operating system crash dumps, user processes, user process core dumps, and object files. For a more detailed description of <code>mdb</code> features, refer to the manual, <i>Solaris Modular Debugger Guide</i>.</p> <p>Debugging is the process of analyzing the execution and state of a software program in order to remove defects. Traditional debugging tools provide facilities for execution control so that programmers can re-execute programs in a controlled environment and display the current state of program data or evaluate expressions in the source language used to develop the program.</p> <p>Unfortunately, these techniques are often inappropriate for debugging complex software systems such as an operating system, where bugs may not be reproducible and program state is massive and distributed, for programs that are highly optimized, have had their debug information removed, or are themselves low-level debugging tools, or for customer situations where the developer can only access post-mortem information.</p> <p><code>mdb</code> provides a completely customizable environment for debugging these programs and scenarios, including a dynamic module facility that programmers can use to implement their own debugging commands to perform program-specific analysis. Each <code>mdb</code> module can be used to examine the program in several different contexts, including live and post-mortem.</p> |
| <b>Definitions</b>  | <p>The <i>target</i> is the program being inspected by the debugger. <code>mdb</code> currently provides support for the following types of targets: user processes, user process core files, the live operating system (via <code>/dev/kmem</code> and <code>/dev/ksyms</code>), operating system crash dumps, user process images recorded inside an operating system crash dump, ELF object files, and raw binary files. Each target exports a standard set of properties, including one or more address spaces, one or more symbol tables, a set of load objects, and a set of threads that can be examined using the debugger commands described below.</p> <p>A debugger command, or <i>dcmd</i> (pronounced dee-command) in <code>mdb</code> terminology, is a routine in the debugger that can access any of the properties of the current target. <code>mdb</code> parses commands from standard input, and then executes the corresponding <code>dcmds</code>. Each <code>dcmd</code> can also accept a list of string or numerical arguments, as shown in the syntax description below. <code>mdb</code> contains a set of built-in <code>dcmds</code>, described below, that are always available. You can also extend the capabilities of <code>mdb</code> itself by writing your own <code>dcmds</code>, as described in the <i>Solaris Modular Debugger Guide</i>.</p>                                                                                                                                                                                                     |

mdb(1)

A *walker* is a set of routines that describe how to walk, or iterate, through the elements of a particular program data structure. A walker encapsulates the data structure's implementation from dcmds and from mdb itself. You can use walkers interactively, or use them as a primitive to build other dcmds or walkers. As with dcmds, you can extend mdb by implementing your own walkers as part of a debugger module.

A debugger module, or *dmod* (pronounced dee-mod), is a dynamically loaded library containing a set of dcmds and walkers. During initialization, mdb will attempt to load dmods corresponding to the load objects present in the target. You can subsequently load or unload dmods at any time while running mdb. mdb ships with a set of standard dmods for debugging the Solaris kernel. The *Solaris Modular Debugger Guide* contains more information on developing your own debugger modules.

A *macro file* is a text file containing a set of commands to execute. Macro files are typically used to automate the process of displaying a simple data structure. mdb provides complete backward compatibility for the execution of macro files written for adb(1), and the Solaris installation includes a set of macro files for debugging the Solaris kernel that may be used with either tool.

#### Syntax

The debugger processes commands from standard input. If standard input is a terminal, mdb provides terminal editing capabilities. mdb can also process commands from macro files and from dcmd pipelines, described below. The language syntax is designed around the concept of computing the value of an expression (typically a memory address in the target), and then applying a dcmd to that address. The current address location is referred to as *dot*, and its value is referenced using ".".

A *metacharacter* is one of the following characters:

```
[] | ! / \ ? = > $: ;
 NEWLINE SPACE TAB
```

A *blank* is a TAB or a SPACE. A *word* is a sequence of characters separated by one or more non-quoted metacharacters. Some of the metacharacters only function as delimiters in certain contexts, as described below. An *identifier* is a sequence of letters, digits, underscores, periods, or backquotes beginning with a letter, underscore, or period. Identifiers are used as the names of symbols, variables, dcmds, and walkers. Commands are delimited by a NEWLINE or semicolon ( ; ).

A dcmd is denoted by one of the following words or metacharacters:

```
/ \ ? = > $character :character ::identifier
```

dcmds named by metacharacters or prefixed by a single \$ or : are provided as built-in operators, and implement complete compatibility with the command set of the legacy adb(1) utility. Once a dcmd has been parsed, the /, \, ?, =, >, \$, and : characters are no longer recognized as metacharacters until the termination of the argument list.

A *simple-command* is a `dcmd` followed by a sequence of zero or more blank-separated words. The words are passed as arguments to the invoked `dcmd`, except as specified under `Quoting` and `Arithmetic Expansion` below. Each `dcmd` returns an exit status that indicates it was either successful, failed, or was invoked with invalid arguments.

A *pipeline* is a sequence of one or more simple commands separated by `|`. Unlike the shell, `dcmds` in `mdb` pipelines are not executed as separate processes. After the pipeline has been parsed, each `dcmd` is invoked in order from left to right. Each `dcmd`'s output is processed and stored as described under `dcmd Pipelines` below. Once the left-hand `dcmd` is complete, its processed output is used as input for the next `dcmd` in the pipeline. If any `dcmd` does not return a successful exit status, the pipeline is aborted.

An *expression* is a sequence of words that is evaluated to compute a 64-bit unsigned integer value. The words are evaluated using the rules described under `Arithmetic Expansion` below.

**Commands** A *command* is one of the following:

*pipeline* [`!` *word* . . .] [`;`]

A simple-command or pipeline can be optionally suffixed with the `!` character, indicating that the debugger should open a `pipe(2)` and send the standard output of the last `dcmd` in the `mdb` pipeline to an external process created by executing `$SHELL -c` followed by the string formed by concatenating the words after the `!` character. For more details, refer to `Shell Escapes` below.

*expression pipeline* [`!` *word* . . .] [`;`]

A simple-command or pipeline can be prefixed with an expression. Before execution of the pipeline, the value of `dot` (the variable denoted by `"."`) is set to the value of the expression.

*expression , expression pipeline* [`!` *word* . . .] [`;`]

A simple-command or pipeline can be prefixed with two expressions. The first is evaluated to determine the new value of `dot`, and the second is evaluated to determine a repeat count for the first `dcmd` in the pipeline. This `dcmd` will be executed *count* times before the next `dcmd` in the pipeline is executed. The repeat count only applies to the first `dcmd` in the pipeline.

*, expression pipeline* [`!` *word* . . .] [`;`]

If the initial expression is omitted, `dot` is not modified but the first `dcmd` in the pipeline will be repeated according to the value of the expression.

*expression* [`!` *word* . . .] [`;`]

A command can consist only of an arithmetic expression. The expression is evaluated and the `dot` variable is set to its value, and then the previous `dcmd` and arguments are executed using the new value of `dot`.

mdb(1)

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                                                                                                                                                                                                                                         |                    |                                                                                                                   |           |                                                                                                                                                                                                                                                                               |                     |                                                        |                   |                                                      |                       |                                  |   |                   |   |                                                      |

| <b>Arithmetic Expansion</b> | <p>Arithmetic expansion is performed when an mdb command is preceded by an optional expression representing a start address, or a start address and a repeat count. Arithmetic expansion can also be performed to compute a numerical argument for a dcmd. An arithmetic expression can appear in an argument list enclosed in square brackets preceded by a dollar sign (\$ [ <i>expression</i> ]), and will be replaced by the value of the expression.</p> <p>Expressions may contain any of the following special words:</p> <table><tr><td><i>integer</i></td><td>The specified integer value. Integer values may be prefixed with 0i or 0I to indicate binary values, 0o or 0O to indicate octal values, 0t or 0T to indicate decimal values, and 0x or 0X to indicate hexadecimal values (the default).</td></tr><tr><td>0[tT][0-9]+.[0-9]+</td><td>The specified decimal floating point value, converted to its IEEE double-precision floating point representation.</td></tr><tr><td>'ccccccc'</td><td>The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters may be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte.</td></tr><tr><td>&lt;<i>identifier</i></td><td>The value of the variable named by <i>identifier</i>.</td></tr><tr><td><i>identifier</i></td><td>The value of the symbol named by <i>identifier</i>.</td></tr><tr><td>(<i>expression</i>)</td><td>The value of <i>expression</i>.</td></tr><tr><td>.</td><td>The value of dot.</td></tr><tr><td>&amp;</td><td>The most recent value of dot used to execute a dcmd.</td></tr></table> | <i>integer</i> | The specified integer value. Integer values may be prefixed with 0i or 0I to indicate binary values, 0o or 0O to indicate octal values, 0t or 0T to indicate decimal values, and 0x or 0X to indicate hexadecimal values (the default). | 0[tT][0-9]+.[0-9]+ | The specified decimal floating point value, converted to its IEEE double-precision floating point representation. | 'ccccccc' | The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters may be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte. | < <i>identifier</i> | The value of the variable named by <i>identifier</i> . | <i>identifier</i> | The value of the symbol named by <i>identifier</i> . | ( <i>expression</i> ) | The value of <i>expression</i> . | . | The value of dot. | & | The most recent value of dot used to execute a dcmd. |
| <i>integer</i>              | The specified integer value. Integer values may be prefixed with 0i or 0I to indicate binary values, 0o or 0O to indicate octal values, 0t or 0T to indicate decimal values, and 0x or 0X to indicate hexadecimal values (the default).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                                                                                                                                                                                                                                         |                    |                                                                                                                   |           |                                                                                                                                                                                                                                                                               |                     |                                                        |                   |                                                      |                       |                                  |   |                   |   |                                                      |
| 0[tT][0-9]+.[0-9]+          | The specified decimal floating point value, converted to its IEEE double-precision floating point representation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                                                                                                                                                                                                                                         |                    |                                                                                                                   |           |                                                                                                                                                                                                                                                                               |                     |                                                        |                   |                                                      |                       |                                  |   |                   |   |                                                      |
| 'ccccccc'                   | The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters may be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                                                                                                                                                                                                                         |                    |                                                                                                                   |           |                                                                                                                                                                                                                                                                               |                     |                                                        |                   |                                                      |                       |                                  |   |                   |   |                                                      |

|---|--------------------------------------------------------|
| + | The value of dot incremented by the current increment. |
| ^ | The value of dot decremented by the current increment. |

The increment is a global variable that stores the total bytes read by the last formatting dcmd. For more information on the increment, refer to the discussion of `Formatting dcmds` below.

Unary operators are right associative and have higher precedence than binary operators. The unary operators are:

|                            |                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>#expression</i>         | Logical negation.                                                                                                                                                             |
| <i>~expression</i>         | Bitwise complement.                                                                                                                                                           |
| <i>-expression</i>         | Integer negation.                                                                                                                                                             |
| <i>%expression</i>         | The value of a pointer-sized quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.                   |
| <i>%/[csil]/expression</i> | The value of a char, short, int, or long-sized quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space. |
| <i>%/[1248]/expression</i> | The value of a one, two, four, or eight-byte quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.   |
| <i>*expression</i>         | The value of a pointer-sized quantity at virtual address <i>expression</i> in the target's virtual address space.                                                             |
| <i>*/[csil]/expression</i> | The value of a char, short, int, or long-sized quantity at virtual address <i>expression</i> in the target's virtual address space.                                           |
| <i>*/[1248]/expression</i> | The value of a one, two, four, or eight-byte quantity at virtual address <i>expression</i> in the target's virtual address space.                                             |

Binary operators are left associative and have lower precedence than unary operators. The binary operators, in order of precedence from highest to lowest, are:

|    |                                                                |
|----|----------------------------------------------------------------|
| *  | Integer multiplication.                                        |
| %  | Integer division.                                              |
| #  | Left-hand side rounded up to next multiple of right-hand side. |
| +  | Integer addition.                                              |
| -  | Integer subtraction.                                           |
| << | Bitwise shift left.                                            |

mdb(1)

|                      |                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |                                                                                        |   |                                                                |   |                                                      |   |                                        |   |                                         |   |                                                                                                                    |   |                                        |

Characters can be quoted (forcing <code>mdb</code> to interpret each character as itself without any special significance) by enclosing them in a pair of single (') or double (") quote marks. A single quote cannot appear within single quotes. Inside double quotes, <code>mdb</code> recognizes the C programming language character escape sequences.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |   |                                                                                        |   |                                                                |   |                                                      |   |                                        |   |                                         |   |                                                                                                                    |   |                                        |
| <b>Shell Escapes</b> |                                                                                                                    | The <code>!</code> character can be used to create a pipeline between an <code>mdb</code> command and the user's shell. If the <code>\$SHELL</code> environment variable is set, <code>mdb</code> will fork and exec this program for shell escapes; otherwise <code>/bin/sh</code> is used. The shell is invoked with the <code>-c</code> option followed by a string formed by concatenating the words after the <code>!</code> character. The <code>!</code> character takes precedence over all other metacharacters, except semicolon ( <code>;</code> ) and <code>NEWLINE</code> . Once a shell escape is detected, the remaining characters up to the next semicolon or <code>NEWLINE</code> are passed as is to the shell. The output of shell commands may not be piped to <code>mdb</code> dcmds. Commands executed by a shell escape have their output sent directly to the terminal, not to <code>mdb</code> .                                                                                                                                                                                                                                                                                                                                                                                                                              |   |                                                                                        |   |                                                                |   |                                                      |   |                                        |   |                                         |   |                                                                                                                    |   |                                        |
| <b>Variables</b>     |                                                                                                                    | <p>A <i>variable</i> is a variable name, a corresponding integer value, and a set of attributes. A variable name is a sequence of letters, digits, underscores, or periods. A variable can be assigned a value using the <code>&gt; dcmd</code> or <code>:: typeset dcmd</code>, and its attributes can be manipulated using the <code>: : typeset dcmd</code>. Each variable's value is represented as a 64-bit unsigned integer. A variable may have one or more of the following attributes: read-only (cannot be modified by the user), persistent (cannot be unset by the user), and tagged (user-defined indicator).</p> <p>The following variables are defined as persistent:</p> <table><tr><td>0</td><td>The most recent value printed using the <code>/, \, ?,</code> or <code>= dcmd</code>.</td></tr><tr><td>9</td><td>The most recent count used with the <code>\$&lt; dcmd</code>.</td></tr><tr><td>b</td><td>The virtual address of the base of the data section.</td></tr><tr><td>d</td><td>The size of the data section in bytes.</td></tr><tr><td>e</td><td>The virtual address of the entry point.</td></tr><tr><td>m</td><td>The initial bytes (magic number) of the target's primary object file, or zero if no object file has been read yet.</td></tr><tr><td>t</td><td>The size of the text section in bytes.</td></tr></table> | 0 | The most recent value printed using the <code>/, \, ?,</code> or <code>= dcmd</code> . | 9 | The most recent count used with the <code>\$&lt; dcmd</code> . | b | The virtual address of the base of the data section. | d | The size of the data section in bytes. | e | The virtual address of the entry point. | m | The initial bytes (magic number) of the target's primary object file, or zero if no object file has been read yet. | t | The size of the text section in bytes. |
| 0                    | The most recent value printed using the <code>/, \, ?,</code> or <code>= dcmd</code> .                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |                                                                                        |   |                                                                |   |                                                      |   |                                        |   |                                         |   |                                                                                                                    |   |                                        |

| hits   | The count of the number of times the matched software event specifier has been matched. See <code>Event Callbacks</code> , below.                                                           |
| thread | The thread identifier of the current representative thread. The value of the identifier depends on the threading model used by the current target. See <code>Thread Support</code> , below. |

In addition, the `mdb` kernel and process targets will export the current values of the representative thread's register set as named variables. The names of these variables will depend on the target's platform and instruction set architecture.

### Symbol Name Resolution

As explained in the `Syntax` description above, a symbol identifier present in an expression context evaluates to the value of this symbol. The value typically denotes the virtual address of the storage associated with the symbol in the target's virtual address space. A target may support multiple symbol tables including, but not limited to, a primary executable symbol table, a primary dynamic symbol table, a run-time link-editor symbol table, and standard and dynamic symbol tables for each of a number of load objects (such as shared libraries in a user process, or kernel modules in the Solaris kernel). The target typically searches the primary executable's symbol tables first, and then one or more of the other symbol tables. Notice that ELF symbol tables only contain entries for external, global, and static symbols; automatic symbols do not appear in the symbol tables processed by `mdb`.

Additionally, `mdb` provides a private user-defined symbol table that is searched prior to any of the target symbol tables. The private symbol table is initially empty, and can be manipulated using the `: :nmadd` and `: :nmde1` dcmds. The `: :nm -P` option can be used to display the contents of the private symbol table. The private symbol table allows the user to create symbol definitions for program functions or data that were either missing from the original program or stripped out. These definitions are then used whenever `mdb` converts a symbolic name to an address, or an address to the nearest symbol.

As targets contain multiple symbol tables, and each symbol table may include symbols from multiple object files, different symbols with the same name may exist. `mdb` uses the backquote ( ``` ) character as a symbol name scoping operator to allow the programmer to obtain the value of the desired symbol in this situation. The programmer can specify the scope used to resolve a symbol name as either: *object`name*, or *file`name*, or *object`file`name*. The object identifier refers to the name of a load object. The file identifier refers to the basename of a source file that has a symbol of type `STT_FILE` in the specified object's symbol table. The object identifier's interpretation depends on the target type.

The `mdb` kernel target expects *object* to specify the basename of a loaded kernel module. For example, the symbol name

```
specfs`_init
```

evaluates to the value of the `_init` symbol in the `specfs` kernel module.

mdb(1)

The mdb process target expects *object* to specify the name of the executable or of a loaded shared library. It may take any of the following forms:

1. An exact match (that is, a full pathname): `/usr/lib/libc.so.1`
2. An exact basename match: `libc.so.1`
3. An initial basename match up to a "." suffix: `libc.so` or `libc`
4. The literal string `a.out` is accepted as an alias for the executable.

The process target will also accept any of the four forms described above preceded by an optional link-map id (lmid). The lmid prefix is specified by an initial "LM" followed by the link-map id in hexadecimal followed by an additional backquote. For example, the symbol name

```
LM0`libc.so.1`_init
```

will evaluate to the value of the `_init` symbol in the `libc.so.1` library that is loaded on link-map 0 (LM\_ID\_BASE). The link-map specifier may be necessary to resolve symbol naming conflicts in the event that the same library is loaded on more than one link map. For more information on link maps, refer to the *Linker and Libraries Guide* and `dlopen(3DL)`. Link-map identifiers will be displayed when symbols are printed according to the setting of the `showlmid` option, as described under OPTIONS, below.

In the case of a naming conflict between symbols and hexadecimal integer values, mdb will attempt to evaluate an ambiguous token as a symbol first, before evaluating it as an integer value. For example, the token `f` may either refer to the decimal integer value 15 specified in hexadecimal (the default base), or to a global variable named `f` in the target's symbol table. If a symbol with an ambiguous name is present, the integer value can be specified by using an explicit `0x` or `0X` prefix.

### dcmd and Walker Name Resolution

As described earlier, each mdb dmod provides a set of dcmds and walkers. dcmds and walkers are tracked in two distinct, global namespaces. mdb also keeps track of a dcmd and walker namespace associated with each dmod. Identically named dcmds or walkers within a given dmod are not allowed: a dmod with this type of naming conflict will fail to load. Name conflicts between dcmds or walkers from different dmods are allowed in the global namespace. In the case of a conflict, the first dcmd or walker with that particular name to be loaded is given precedence in the global namespace. Alternate definitions are kept in a list in load order. The backquote character (```) may be used in a dcmd or walker name as a scoping operator to select an alternate definition. For example, if dmods `m1` and `m2` each provide a dcmd `d`, and `m1` is loaded prior to `m2`, then:

```
::d Executes m1's definition of d.
::m1`d Executes m1's definition of d.
::m2`d Executes m2's definition of d.
```

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | <p>If module <code>m1</code> were now unloaded, the next <code>dcmd</code> on the global definition list (<code>m2 `d</code>) would be promoted to global visibility. The current definition of a <code>dcmd</code> or walker can be determined using the <code>::which dcmd</code>, described below. The global definition list can be displayed using the <code>::which -v</code> option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>dcmd Pipelines</b>   | <p><code>dcmds</code> can be composed into a pipeline using the <code> </code> operator. The purpose of a pipeline is to pass a list of values, typically virtual addresses, from one <code>dcmd</code> or walker to another. Pipeline stages might be used to map a pointer from one type of data structure to a pointer to a corresponding data structure, to sort a list of addresses, or to select the addresses of structures with certain properties.</p> <p><code>mdb</code> executes each <code>dcmd</code> in the pipeline in order from left to right. The leftmost <code>dcmd</code> is executed using the current value of <code>dot</code>, or using the value specified by an explicit expression at the start of the command. When a <code> </code> operator is encountered, <code>mdb</code> creates a pipe (a shared buffer) between the output of the <code>dcmd</code> to its left and the <code>mdb</code> parser, and an empty list of values. As the <code>dcmd</code> executes, its standard output is placed in the pipe and then consumed and evaluated by the parser, as if <code>mdb</code> were reading this data from standard input. Each line must consist of an arithmetic expression terminated by a <code>NEWLINE</code> or semicolon (<code>;</code>). The value of the expression is appended to the list of values associated with the pipe. If a syntax error is detected, the pipeline is aborted.</p> <p>When the <code>dcmd</code> to the left of a <code> </code> operator completes, the list of values associated with the pipe is then used to invoke the <code>dcmd</code> to the right of the <code> </code> operator. For each value in the list, <code>dot</code> is set to this value and the right-hand <code>dcmd</code> is executed. Only the rightmost <code>dcmd</code> in the pipeline has its output printed to standard output. If any <code>dcmd</code> in the pipeline produces output to standard error, these messages are printed directly to standard error and are not processed as part of the pipeline.</p> |
| <b>Signal Handling</b>  | <p>The debugger ignores the <code>PIPE</code> and <code>QUIT</code> signals. The <code>INT</code> signal aborts the command that is currently executing. The debugger intercepts and provides special handling for the <code>ILL</code>, <code>TRAP</code>, <code>EMT</code>, <code>FPE</code>, <code>BUS</code>, and <code>SEGV</code> signals. If any of these signals are generated asynchronously (that is, delivered from another process using <code>kill(2)</code>), <code>mdb</code> will restore the signal to its default disposition and dump core. However, if any of these signals are generated synchronously by the debugger process itself and a <code>dcmd</code> from an externally loaded <code>dmod</code> is currently executing, and standard input is a terminal, <code>mdb</code> will provide a menu of choices allowing the user to force a core dump, quit without producing a core dump, stop for attach by a debugger, or attempt to resume. The resume option will abort all active commands and unload the <code>dmod</code> whose <code>dcmd</code> was active at the time the fault occurred. It can then be subsequently re-loaded by the user. The resume option provides limited protection against buggy <code>dcmds</code>. Refer to <code>WARNINGS</code>, <code>Use of the Error Recovery Mechanism</code>, below for information about the risks associated with the resume option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Command Re-entry</b> | <p>The text of the last <code>HISTSIZE</code> (default 128) commands entered from a terminal device are saved in memory. The in-line editing facility, described next, provides key mappings for searching and fetching elements from the history list.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

mdb(1)

### In-line Editing

If standard input is a terminal device, mdb provides some simple emacs-style facilities for editing the command line. The `search`, `previous`, and `next` commands in edit mode provide access to the history list. Only strings, not patterns, are matched when searching. In the table below, the notation for control characters is caret (^) followed by a character shown in upper case. The notation for escape sequences is M- followed by a character. For example, M-f (pronounced meta-eff) is entered by depressing ESC followed by 'f', or by depressing Meta followed by 'f' on keyboards that support a Meta key. A command line is committed and executed using RETURN or NEWLINE. The edit commands are:

|                     |                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ^F                  | Move cursor forward (right) one character.                                                                                                                                                                                                              |
| M-f                 | Move cursor forward one word.                                                                                                                                                                                                                           |
| ^B                  | Move cursor backward (left) one character.                                                                                                                                                                                                              |
| M-b                 | Move cursor backward one word.                                                                                                                                                                                                                          |
| ^A                  | Move cursor to start of line.                                                                                                                                                                                                                           |
| ^E                  | Move cursor to end of line.                                                                                                                                                                                                                             |
| ^D                  | Delete current character, if the current line is not empty. If the current line is empty, ^D denotes EOF and the debugger will exit.                                                                                                                    |
| M-^H                | (Meta-backspace) Delete previous word.                                                                                                                                                                                                                  |
| ^K                  | Delete from the cursor to the end of the line.                                                                                                                                                                                                          |
| ^L                  | Clear the screen and reprint the current line.                                                                                                                                                                                                          |
| ^T                  | Transpose current character with next character.                                                                                                                                                                                                        |
| ^N                  | Fetch the next command from the history. Each time ^N is entered, the next command forward in time is retrieved.                                                                                                                                        |
| ^P                  | Fetch the previous command from the history. Each time ^P is entered, the next command backward in time is retrieved.                                                                                                                                   |
| ^R[ <i>string</i> ] | Search backward in the history for a previous command line containing <i>string</i> . The string should be terminated by a RETURN or NEWLINE. If <i>string</i> is omitted, the previous history element containing the most recent string is retrieved. |

The editing mode also interprets the following user-defined sequences as editing commands. User defined sequences can be read or modified using the `stty(1)` command.

|       |                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------|
| erase | User defined erase character (usually ^H or ^?). Delete previous character.                      |
| intr  | User defined interrupt character (usually ^C). Abort the current command and print a new prompt. |

|         |                                                                                 |
|---------|---------------------------------------------------------------------------------|
| kill    | User defined kill character (usually ^U). Kill the entire current command line. |
| quit    | User defined quit character (usually ^\). Quit the debugger.                    |
| suspend | User defined suspend character (usually ^Z). Suspend the debugger.              |
| werase  | User defined word erase character (usually ^W). Erase the preceding word.       |

On keyboards that support an extended keypad with arrow keys, mdb will interpret these keystrokes as editing commands:

|             |                                                           |
|-------------|-----------------------------------------------------------|
| up-arrow    | Fetch the previous command from the history (same as ^P). |
| down-arrow  | Fetch the next command from the history (same as ^N).     |
| left-arrow  | Move cursor backward one character (same as ^B).          |
| right-arrow | Move cursor forward one character (same as ^F).           |

### Output Pager

mdb provides a built-in output pager. The output pager is enabled if the debugger's standard output is a terminal device. Each time a command is executed, mdb will pause after one screenful of output is produced and will display a pager prompt:

```
>> More [<space>, <cr>, q, n, c, a] ?
```

The following key sequences are recognized by the pager:

|                       |                                                                                                               |
|-----------------------|---------------------------------------------------------------------------------------------------------------|
| SPACE                 | Display the next screenful of output.                                                                         |
| a, A                  | Abort the current top-level command and return to the prompt.                                                 |
| c, C                  | Continue displaying output without pausing at each screenful until the current top-level command is complete. |
| n, N, NEWLINE, RETURN | Display the next line of output.                                                                              |
| q, Q, ^C, ^\          | Quit (abort) the current dcmd only.                                                                           |

### Formatting dcmds

The /, \, ?, and = metacharacters are used to denote the special output formatting dcmds. Each of these dcmds accepts an argument list consisting of one or more format characters, repeat counts, or quoted strings. A format character is one of the ASCII characters shown in the table below. Format characters are used to read and format data from the target. A repeat count is a positive integer preceding the format character that is always interpreted in base 10 (decimal). A repeat count may also be specified as an expression enclosed in square brackets preceded by a dollar sign (\$ [ ]). A string argument must be enclosed in double-quotes (" "). No blanks are necessary between format arguments.

The formatting dcmds are:

## mdb(1)

|   |                                                                                                                                                               |
|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| / | Display data from the target's virtual address space starting at the virtual address specified by dot.                                                        |
| \ | Display data from the target's physical address space starting at the physical address specified by dot.                                                      |
| ? | Display data from the target's primary object file starting at the object file location corresponding to the virtual address specified by dot.                |
| = | Display the value of dot itself in each of the specified data formats. The = dcmd is therefore useful for converting between bases and performing arithmetic. |

In addition to dot, mdb keeps track of another global value called the *increment*. The increment represents the distance between dot and the address following all the data read by the last formatting dcmd. For example, if a formatting dcmd is executed with dot equal to address A, and displays a 4-byte integer, then after this dcmd completes, dot is still A, but the increment is set to 4. The + character (described under *Arithmetic Expansion* above) would now evaluate to the value A + 4, and could be used to reset dot to the address of the next data object for a subsequent dcmd.

Most format characters increase the value of the increment by the number of bytes corresponding to the size of the data format, shown in the table. The table of format characters can be displayed from within mdb using the `::formats` dcmd. The format characters are:

|   |                                                      |
|---|------------------------------------------------------|
| + | increment dot by the count (variable size)           |
| - | decrement dot by the count (variable size)           |
| B | hexadecimal int (1 byte)                             |
| C | character using C character notation (1 byte)        |
| D | decimal signed int (4 bytes)                         |
| E | decimal unsigned long long (8 bytes)                 |
| F | double (8 bytes)                                     |
| G | octal unsigned long long (8 bytes)                   |
| H | swap bytes and shorts (4 bytes)                      |
| I | address and disassembled instruction (variable size) |
| J | hexadecimal long long (8 bytes)                      |
| K | hexadecimal uintptr_t (4 or 8 bytes)                 |
| N | newline                                              |
| O | octal unsigned int (4 bytes)                         |

|   |                                                    |
|---|----------------------------------------------------|
| P | symbol (4 or 8 bytes)                              |
| Q | octal signed int (4 bytes)                         |
| R | binary int (8 bytes)                               |
| S | string using C string notation (variable size)     |
| T | horizontal tab                                     |
| U | decimal unsigned int (4 bytes)                     |
| V | decimal unsigned int (1 byte)                      |
| W | default radix unsigned int (4 bytes)               |
| X | hexadecimal int (4 bytes)                          |
| Y | decoded time32_t (4 bytes)                         |
| Z | hexadecimal long long (8 bytes)                    |
| ^ | decrement dot by increment * count (variable size) |
| a | dot as symbol+offset                               |
| b | octal unsigned int (1 byte)                        |
| c | character (1 byte)                                 |
| d | decimal signed short (2 bytes)                     |
| e | decimal signed long long (8 bytes)                 |
| f | float (4 bytes)                                    |
| g | octal signed long long (8 bytes)                   |
| h | swap bytes (2 bytes)                               |
| i | disassembled instruction (variable size)           |
| n | newline                                            |
| o | octal unsigned short (2 bytes)                     |
| p | symbol (4 or 8 bytes)                              |
| q | octal signed short (2 bytes)                       |
| r | whitespace                                         |
| s | raw string (variable size)                         |
| t | horizontal tab                                     |
| u | decimal unsigned short (2 bytes)                   |
| v | decimal signed int (1 byte)                        |

## mdb(1)

|   |                                        |
|---|----------------------------------------|
| w | default radix unsigned short (2 bytes) |
| x | hexadecimal short (2 bytes)            |
| y | decoded time64_t (8 bytes)             |

The /, \, and ? formatting dcmts can also be used to write to the target's virtual address space, physical address space, or object file by specifying one of the following modifiers as the first format character, and then specifying a list of words that are either immediate values or expressions enclosed in square brackets preceded by a dollar sign (\$ [ ]).

The write modifiers are:

|   |                                                                                                                      |
|---|----------------------------------------------------------------------------------------------------------------------|
| v | Write the lowest byte of the value of each expression to the target beginning at the location specified by dot.      |
| w | Write the lowest two bytes of the value of each expression to the target beginning at the location specified by dot. |
| W | Write the lowest 4 bytes of the value of each expression to the target beginning at the location specified by dot.   |
| Z | Write the complete 8 bytes of the value of each expression to the target beginning at the location specified by dot. |

The /, \, and ? formatting dcmts can also be used to search for a particular integer value in the target's virtual address space, physical address space, and object file, respectively, by specifying one of the following modifiers as the first format character, and then specifying a value and optional mask. The value and mask are each specified as either immediate values or expressions enclosed in square brackets preceded by a dollar sign. If only a value is specified, mdb reads integers of the appropriate size and stops at the address containing the matching value. If a value V and mask M are specified, mdb reads integers of the appropriate size and stops at the address containing a value X where  $(X \& M) == V$ . At the completion of the dcmd, dot is updated to the address containing the match. If no match is found, dot is left at the last address that was read.

The search modifiers are:

|   |                                        |
|---|----------------------------------------|
| l | Search for the specified 2-byte value. |
| L | Search for the specified 4-byte value. |
| M | Search for the specified 8-byte value. |

Notice that for both user and kernel targets, an address space is typically composed of a set of discontinuous segments. It is not legal to read from an address that does not have a corresponding segment. If a search reaches a segment boundary without finding a match, it will abort when the read past the end of the segment boundary fails.

## Execution Control

`mdb` provides facilities for controlling and tracing the execution of a live running program. Currently, only the user process target provides support for execution control. `mdb` provides a simple model of execution control: a target process can be started from within the debugger using `::run`, or `mdb` can attach to an existing process using `:A`, `::attach`, or the `-p` command-line option, as described below. A list of traced software events can be specified by the user. Each time a traced event occurs in the target process, all threads in the target stop, the thread that triggered the event is chosen as the representative thread, and control returns to the debugger. Once the target program is set running, control can be asynchronously returned to the debugger by typing the user-defined interrupt character (typically `^C`).

A *software event* is a state transition in the target program that is observed by the debugger. For example, the debugger may observe the transition of a program counter register to a value of interest (a breakpoint) or the delivery of a particular signal.

A *software event specifier* is a description of a class of software events that is used by the debugger to instrument the target program in order to observe these events. The `::events` dcmd is used to list the software event specifiers. A set of standard properties is associated with each event specifier, as described under `::events`, below.

The debugger can observe a variety of different software events, including breakpoints, watchpoints, signals, machine faults, and system calls. New specifiers can be created using `::bp`, `::fltbp`, `::sigbp`, `::sysbp`, or `::wp`. Each specifier has an associated callback (an `mdb` command string to execute as if it had been typed at the command prompt) and a set of properties, as described below. Any number of specifiers for the same event may be created, each with different callbacks and properties. The current list of traced events and the properties of the corresponding event specifiers can be displayed using the `::events` dcmd. The event specifier properties are defined as part of the description of the `::events` and `::evset` dcmds, below.

The execution control built-in dcmds, described below, are always available, but will issue an error message indicating they are not supported if applied to a target that does not support execution control. For more information about the interaction of `exec`, `attach`, `release`, and `job` control with debugger execution control, refer to NOTES, below.

## Event Callbacks

The `::evset` dcmd and event tracing dcmds allow you to associate an event callback (using the `-c` option) with each event specifier. The event callbacks are strings that represent `mdb` commands to execute when the corresponding event occurs in the target. These commands are executed as if they had been typed at the command

mdb(1)

prompt. Before executing each callback, the dot variable is set to the value of the representative thread's program counter and the "hits" variable is set to the number of times this specifier has been matched, including the current match.

If the event callbacks themselves contain one or more commands to continue the target (for example, `::cont` or `::step`), these commands do not immediately continue the target and wait for it to stop again. Instead, inside of an event callback, the continue dcmds note that a continue operation is now pending, and then return immediately. Therefore, if multiple dcmds are included in an event callback, the step or continue dcmd should be the last command specified. Following the execution of *all* event callbacks, the target will immediately resume execution if *all* matching event callbacks requested a continue. If conflicting continue operations are requested, the operation with the highest precedence determines what type of continue will occur. The order of precedence from highest to lowest is: step, step-over (next), step-out, continue.

### Thread Support

mdb provides facilities to examine the stacks and registers of each thread associated with the target. The persistent "thread" variable contains the current representative thread identifier. The format of the thread identifier depends on the target. The `::regs` and `::fregs` dcmds can be used to examine the register set of the representative thread, or of another thread if its register set is currently available. In addition, the register set of the representative thread is exported as a set of named variables. The user can modify the value of one or more registers by applying the `>` dcmd to the corresponding named variable.

The mdb kernel target exports the virtual address of the corresponding internal thread structure as the identifier for a given thread. The *Solaris Modular Debugger Guide* provides more information on debugging support for threads in the Solaris kernel. The mdb process target provides proper support for examination of multi-threaded user processes that use the native `lwp_*` interfaces, `/usr/lib/libthread.so` or `/usr/lib/lwp/libthread.so`. When debugging a live user process, mdb will detect if a single threaded process `dlopen`s or closes `libthread` and will automatically adjust its view of the threading model on-the-fly. The process target thread identifiers will correspond to either the `lwpid_t`, `thread_t`, or `pthread_t` of the representative, depending on the threading model used by the application.

If mdb is debugging a user process target and the target makes use of compiler-supported thread-local storage, mdb will automatically evaluate symbol names referring to thread-local storage to the address of the storage corresponding to the current representative thread. The `::tls` built-in dcmd can be used to display the value of the symbol for threads other than the representative thread.

### Built-in dcmds

mdb provides a set of built-in dcmds that are always defined. Some of these dcmds are only applicable to certain targets: if a dcmd is not applicable to the current target, it will fail and print a message indicating "command is not supported by current target". In many cases, mdb provides a mnemonic equivalent (`::identifier`) for the legacy `adb(1)` dcmd names. For example, `::quit` is provided as the equivalent of `$q`. Programmers who are experienced with `adb(1)` or who appreciate brevity or arcana may prefer the `$` or `:` forms of the built-ins. Programmers who are new to mdb may

prefer the more verbose `::` form. The built-ins are shown in alphabetical order. If a `$` or `:` form has a `::identifier` equivalent, it is shown underneath the `::identifier` form. The built-in dcmds are:

`> variable-name`

`>/modifier/variable-name`

Assign the value of dot to the specified named variable. Some variables are read-only and may not be modified. If the `>` is followed by a modifier character surrounded by `/ /`, then the value is modified as part of the assignment. The modifier characters are:

|                |                                                             |
|----------------|-------------------------------------------------------------|
| <code>c</code> | unsigned char quantity (1-byte)                             |
| <code>s</code> | unsigned short quantity (2-byte)                            |
| <code>i</code> | unsigned int quantity (4-byte)                              |
| <code>l</code> | unsigned long quantity (4-byte in 32-bit, 8-byte in 64-bit) |

Notice that these operators do not perform a cast. Instead, they fetch the specified number of low-order bytes (on little-endian architectures) or high-order bytes (big-endian architectures). Modifiers are provided for backwards compatibility; the `mdb */modifier/` and `*/modifier/` syntax should be used instead.

`$< macro-name`

Read and execute commands from the specified macro file. The filename may be given as an absolute or relative path. If the filename is a simple name (that is, if it does not contain a `'/'`), `mdb` will search for it in the macro file include path. If another macro file is currently being processed, this file is closed and replaced with the new file.

`$<< macro-name`

Read and execute commands from the specified macro file (as with `$<`), but do not close the current open macro file.

`$?`

Print the process-ID and current signal of the target if it is a user process or core file, and then print the general register set of the representative thread.

`[ address ] $C [ count ]`

Print a C stack backtrace, including stack frame pointer information. If the dcmd is preceded by an explicit *address*, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than *count* arguments are displayed for each stack frame in the output.

`[ base ] $d`

Get or set the default output radix. If the dcmd is preceded by an explicit expression, the default output radix is set to the given *base*; otherwise the current radix is printed in base 10 (decimal). The default radix is base 16 (hexadecimal).

**\$e**

Print a list of all known external (global) symbols of type object or function, the value of the symbol, and the first 4 (32-bit mdb) or 8 (64-bit mdb) bytes stored at this location in the target's virtual address space. The `::nm dcmd` provides more flexible options for displaying symbol tables.

**\$P** *prompt-string*

Set the prompt to the specified *prompt-string*. The default prompt is `'>'`. The prompt can also be set using `::set -P` or the `-P` command-line option.

*distance* **\$s**

Get or set the symbol matching *distance* for address-to-symbol-name conversions. The symbol matching distance modes are discussed along with the `-s` command-line option under **OPTIONS**, below. The symbol matching distance may also be modified using the `::set -s` option. If no distance is specified, the current setting is displayed.

**\$v**

Print a list of the named variables that have non-zero values. The `::vars dcmd` provides other options for listing variables.

*width* **\$w**

Set the output page *width* to the specified value. Typically, this command is not necessary as mdb queries the terminal for its width and handles resize events.

**\$W**

Re-open the target for writing, as if mdb had been executed with the `-w` option on the command line. Write mode can also be enabled with the `::set -w` option.

**[ pid ] ::attach [ core | pid ]****[ pid ] :A [ core | pid ]**

If the user process target is active, attach to and debug the specified process-ID or *core* file. The *core* file pathname should be specified as a string argument. The process-ID may be specified as the string argument, or as the value of the expression preceding the dcmd. Recall that the default base is hexadecimal, so decimal PIDs obtained using `grep(1)` or `ps(1)` should be preceded with `"0t"` when specified as expressions.

**[address] ::bp [+/-dDesT] [-c cmd] [-n count] sym ...****address :b [cmd ...]**

Set a breakpoint at the specified locations. The `::bp dcmd` sets a breakpoint at each address or symbol specified, including an optional address specified by an explicit expression preceding the dcmd, and each string or immediate value following the dcmd. The arguments may either be symbol names or immediate values denoting a particular virtual address of interest. If a symbol name is specified, it may refer to a symbol that cannot yet be evaluated in the target process. That is, it may consist of an object name and function name in a load object that has not yet been opened. In this case, the breakpoint is deferred and it will not be active in the target until an object matching the given name is loaded. The breakpoint will be automatically enabled when the load object is opened. Breakpoints on symbols defined in a shared library should always be set using a symbol name and not using an address

expression, as the address may refer to the corresponding Procedure Linkage Table (PLT) entry instead of the actual symbol definition. Breakpoints set on PLT entries may be overwritten by the run-time link-editor when the PLT entry is subsequently resolved to the actual symbol definition. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset dcmd`, as described below. If the `:b` form of the `dcmd` is used, a breakpoint is only set at the virtual address specified by the expression preceding the `dcmd`. The arguments following the `:b dcmd` are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

`::cat filename ...`

Concatenate and display files. Each filename may specified as a relative or absolute pathname. The file contents will be printed to standard output, but will not be passed to the output pager. This `dcmd` is intended to be used with the `|` operator; the programmer can initiate a pipeline using a list of addresses stored in an external file.

`::cont [ SIG ]`

`:c [ SIG ]`

Suspend the debugger, continue the target program, and wait for it to terminate or stop following a software event of interest. If the target is already running because the debugger was attached to a running program with the `-o nostop` option enabled, this `dcmd` simply waits for the target to terminate or stop after an event of interest. If an optional signal name or number (see `signal(3HEAD)`) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If the `SIGINT` signal is traced, control may be asynchronously returned to the debugger by typing the user-defined interrupt character (usually `^C`). This `SIGINT` signal will be automatically cleared and will not be observed by the target the next time it is continued. If no target program is currently running, `::cont` will start a new program running as if by `::run`.

`address ::context`

`address $p`

Context switch to the specified process. A context switch operation is only valid when using the kernel target. The process context is specified using the *address* of its `proc` structure in the kernel's virtual address space. The special context address "0" is used to denote the context of the kernel itself. `mdb` can only perform a context switch when examining a crash dump if the dump contains the physical memory pages of the specified user process (as opposed to just kernel pages). The kernel crash dump facility can be configured to dump all pages or the pages of the current user process using `dumpadm(1M)`. The `::status dcmd` can be used to display the contents of the current crash dump.

When the user requests a context switch from the kernel target, `mdb` constructs a new target representing the specified user process. Once the switch occurs, the new target interposes its `dcmds` at the global level: thus the `/ dcmd` will now format and display data from the virtual address space of the user process, the `::mappings dcmd` will display the mappings in the address space of the user process, and so on. The kernel target can be restored by executing `0 ::context`.

## mdb(1)

```
::dcmds
 List the available dcmds and print a brief description for each one.

[address] ::delete [id | all]
[address] :d [id | all]
 Delete the event specifiers with the given id number. The id number argument is interpreted in decimal by default. If an optional address is specified preceding the dcmd, all event specifiers that are associated with the given virtual address are deleted (for example, all breakpoints or watchpoints affecting that address). If the special argument "all" is given, all event specifiers are deleted, except those that are marked sticky (T flag). The ::events dcmd displays the current list of event specifiers.

[address] ::dis [-fw] [-n count] [address]
 Disassemble starting at or around the address specified by the final argument, or the current value of dot. If the address matches the start of a known function, the entire function is disassembled. Otherwise, a "window" of instructions before and after the specified address is printed in order to provide context. By default, instructions are read from the target's virtual address space. If the -f option is present, instructions are read from the target's object file instead. The -f option is enabled by default if the debugger is not currently attached to a live process, core file, or crash dump. The -w option can be used to force "window"-mode, even if the address is the start of a known function. The size of the window defaults to ten instructions; the number of instructions can be specified explicitly using the -n option.

::disasms
 List the available disassembler modes. When a target is initialized, mdb will attempt to select the appropriate disassembler mode. The user can change the mode to any of the modes listed using the ::dismode dcmd.

::dismode [mode]
$V [mode]
 Get or set the disassembler mode. If no argument is specified, print the current disassembler mode. If a mode argument is specified, switch the disassembler to the specified mode. The list of available disassemblers can be displayed using the ::disasms dcmd.

::dmods [-l] [module-name]
 List the loaded debugger modules. If the -l option is specified, the list of the dcmds and walkers associated with each dmod is printed below its name. The output can be restricted to a particular dmod by specifying its name as an additional argument.

[address] ::dump [-eqrstuv] [-f | -p]
[-g bytes] [-w paragraphs]
 Print a hexadecimal and ASCII memory dump of the 16-byte aligned region of memory containing the address specified by dot. If a repeat count is specified for ::dump, this is interpreted as a number of bytes to dump rather than a number of iterations. The ::dump dcmd also recognizes the following options:
```

-e Adjusts for endian-ness. The -e option assumes 4-byte words. The -g option can be used to change the default word size.

-f Reads data from the object file location corresponding to the given virtual address instead of from the target's virtual address space. The -f option is enabled by default if the debugger is not currently attached to a live process, core file, or crash dump.

-g *bytes* Displays bytes in groups of *bytes*. The default group size is 4 bytes. The group size must be a power of two that divides the line width.

-p Interprets *address* as a physical address location in the target's address space instead of a virtual address.

-q Does not print an ASCII decoding of the data.

-r Numbers lines relative to the start address instead of with the explicit address of each line. This option implies the -u option.

-s Elides repeated lines.

-t Only reads from and displays the contents of the specified addresses, instead of reading and printing entire lines.

-u Unaligns output instead of aligning the output at a paragraph boundary.

-w *paragraphs* Displays paragraphs at 16-byte paragraphs per line. The default number of *paragraphs* is one. The maximum value accepted for -w is 16.

::echo [ *string* | *value* ...]  
Print the arguments separated by blanks and terminated by a NEWLINE to standard output. Expressions enclosed in \$ [ ] will be evaluated to a value and printed in the default base.

::eval *command*  
Evaluate and execute the specified string as a command. If the command contains metacharacters or whitespace, it should be enclosed in double or single quotes.

::events [ -av ]  
\$b [ -av ]  
Display the list of software event specifiers. Each event specifier is assigned a unique ID number that can be used to delete or modify it at a later time. The debugger may also have its own internal events enabled for tracing. These events will only be displayed if the -a option is present. If the -v option is present, a more verbose display, including the reason for any specifier inactivity, will be shown. Here is some sample output:

```
> ::events
 ID S TA HT LM Description Action

```

mdb(1)

```
[1] - T 1 0 stop on SIGINT -
[2] - T 0 0 stop on SIGQUIT -
[3] - T 0 0 stop on SIGILL -
...
[11] - T 0 0 stop on SIGXCPU -
[12] - T 0 0 stop on SIGXFSZ -
[13] - 2 0 stop at libc'printf ::echo printf
>
```

The following table explains the meaning of each column. A summary of this information is available using `::help events`.

|    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID | The event specifier identifier. The identifier will be shown in square brackets [ ] if the specifier is enabled, in parentheses ( ) if the specifier is disabled, or in angle brackets < > if the target program is currently stopped on an event that matches the given specifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| S  | The event specifier state. The state will be one of the following symbols: <ul style="list-style-type: none"><li>- The event specifier is idle. When no target program is running, all specifiers are idle. When the target program is running, a specifier may be idle if it cannot be evaluated (for example, a deferred breakpoint in a shared object that is not yet loaded).</li><li>+ The event specifier is active. When the target is continued, events of this type will be detected by the debugger.</li><li>* The event specifier is armed. This state means that the target is currently running with instrumentation for this type of event. This state is only visible if the debugger is attached to a running program with the <code>-o nostop</code> option.</li><li>! The event specifier was not armed due to an operating system error. The <code>::events -v</code> option can be used to display more information about the reason the instrumentation failed.</li></ul> |
| TA | The Temporary, Sticky, and Automatic event specifier properties. One or more of the following symbols may be shown: <ul style="list-style-type: none"><li>t The event specifier is temporary, and will be deleted the next time the target stops, regardless of whether it is matched.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|             |                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T           | The event specifier is sticky, and will be not be deleted by <code>::delete all</code> or <code>:z</code> . The specifier can be deleted by explicitly specifying its id number to <code>::delete</code> .                                      |
| d           | The event specifier will be automatically disabled when the hit count is equal to the hit limit.                                                                                                                                                |
| D           | The event specifier will be automatically deleted when the hit count is equal to the hit limit.                                                                                                                                                 |
| s           | The target will automatically stop when the hit count is equal to the hit limit.                                                                                                                                                                |
| HT          | The current hit count. This column displays the number of times the corresponding software event has occurred in the target since the creation of this event specifier.                                                                         |
| LM          | The current hit limit. This column displays the limit on the hit count at which the auto-disable, auto-delete, or auto-stop behavior will take effect. These behaviors can be configured using the <code>::evset dcmd</code> , described below. |
| Description | A description of the type of software event that is matched by the given specifier.                                                                                                                                                             |
| Action      | The callback string to execute when the corresponding software event occurs. This callback is executed as if it had been typed at the command prompt.                                                                                           |

`[id] ::evset [+/-dDestT] [-c cmd] [-n count] id ...`

Modify the properties of one or more software event specifiers. The properties are set for each specifier identified by the optional expression preceding the `dcmd` and an optional list of arguments following the `dcmd`. The argument list is interpreted as a list of decimal integers, unless an explicit radix is specified. The `::evset dcmd` recognizes the following options:

- d Disables the event specifier when the hit count reaches the hit limit. If the `+d` form of the option is given, this behavior is disabled. Once an event specifier is disabled, the debugger will remove any corresponding instrumentation and will ignore the corresponding software events until the specifier is subsequently re-enabled. If the `-n` option is not present, the specifier is disabled immediately.
- D Deletes the event specifier when the hit count reaches the hit limit. If the `+D` form of the option is given, this behavior is disabled. The `-D` option takes precedence over the `-d` option. The hit limit can be configured using the `-n` option.
- e Enables the event specifier. If the `+e` form of the option is given, the specifier is disabled.

## mdb(1)

- s Stops the target program when the hit count reaches the hit limit. If the +s form of the option is given, this behavior is disabled. The -s behavior tells the debugger to act as if the ::cont were issued following each execution of the specifier's callback, except for the Nth execution, where N is the current value of the specifier's hit limit. The -s option takes precedence over both the -D option and the -d option.
- t Marks the event specifier as temporary. Temporary specifiers are automatically deleted the next time the target stops, regardless of whether it stopped as the result of a software event corresponding to the given specifier. If the +t form of the option is given, the temporary marker is removed. The -t option takes precedence over the -T option.
- T Marks the event specifier as sticky. Sticky specifiers will not be deleted by ::delete all or :z. They can be deleted by specifying the corresponding specifier ID as an explicit argument to ::delete. If the +T form of the option is given, the sticky property is removed. The default set of event specifiers are all initially marked sticky.
- c Executes the specified *cmd* string each time the corresponding software event occurs in the target program. The current callback string can be displayed using ::events.
- n Sets the current value of the hit limit to *count*. If no hit limit is currently set and the -n option does not accompany -s or D, the hit limit will be set to one.

A summary of this information is available using ::help evset.

::files

\$f

Print a list of the known source files (symbols of type STT\_FILE present in the various target symbol tables).

[*flt*] ::fltbp [+/-dDestT] [-c *cmd*] [-n *count*] *flt* ...

Trace the specified machine faults. The faults are identified using an optional fault number preceding the *dcmd*, or a list of fault names or numbers (see <sys/fault.h>) following the *dcmd*. The -d, -D, -e, -s, -t, -T, -c, and -n options have the same meaning as they do for the ::evset *dcmd*.

[*thread*] ::fpregs

[*thread*] \$x, \$X, \$y, \$Y

Print the floating-point register set of the representative thread. If a thread is specified, the floating point registers of that thread are displayed. The thread expression should be one of the thread identifiers described under Thread Support, above.

::formats

List the available output format characters for use with the /, \, ?, and = formatting *dcmds*. The formats and their use is described under Formatting *dcmds*, above.

`::grep command`

Evaluate the specified command string, and then print the old value of dot if the new value of dot is non-zero. If the *command* contains whitespace or metacharacters, it must be quoted. The `::grep dcmd` can be used in pipelines to filter a list of addresses.

`::help [ dcmd-name ]`

With no arguments, the `::help dcmd` prints a brief overview of the help facilities available in mdb. If a *dcmd-name* is specified, mdb will print a usage summary for that dcmd.

*signal* :i

If the target is a live user process, ignore the specified signal and allow it to be delivered transparently to the target. All event specifiers that are tracing delivery of the specified signal will be deleted from the list of traced events. By default, the set of ignored signals is initialized to the complement of the set of signals that cause a process to dump core by default (see `signal(3HEAD)`), except for SIGINT, which is traced by default.

\$i

Display the list of signals that are ignored by the debugger and that will be handled directly by the target. More information on traced signals can be obtained using the `::events dcmd`.

`::kill`

:k

Forcibly terminate the target if it is a live user process. The target will also be forcibly terminated when the debugger exits if it was created by the debugger using `::run`.

\$l

Print the LWPID of the representative thread, if the target is a user process.

\$L

Print the LWPIDs of each LWP in the target, if the target is a user process.

[ *address* ] ::list *type member* [ *variable-name* ]

Walk through the elements of a linked list data structure and print the address of each element in the list. The address of the first element in the list can be specified using an optional address. Otherwise, the list is assumed to start at the current value of dot. The type parameter must name a C struct or union type and is used to describe the type of the list elements so that mdb can read in objects of the appropriate size. The member parameter is used to name the *member of type* that contains a pointer to the next list element. The `::list dcmd` will continue iterating until a NULL pointer is encountered, the first element is reached again (a circular list), or an error occurs while reading an element. If the optional *variable-name* is specified, the specified variable will be assigned the value returned at each step of the walk when mdb invokes the next stage of a pipeline. The `::list dcmd` may only be used with objects that contain symbolic debugging information designed for use with mdb. Refer to NOTES, Symbolic Debugging Information, below for more information.

## mdb(1)

```
::load [-s] module-name
 Load the specified dmod. The module name may be given as an absolute or relative
 path. If module-name is a simple name (that is, does not contain a '/'), mdb will
 search for it in the module library path. Modules with conflicting names may not be
 loaded; the existing module must be unloaded first. If the -s option is present, mdb
 will remain silent and not issue any error messages if the module is not found or
 could not be loaded.

::log [-d | [-e] filename]
$> [filename]
 Enable or disable the output log. mdb provides an interactive logging facility where
 both the input commands and standard output can be logged to a file while still
 interacting with the user. The -e option enables logging to the specified file, or
 re-enables logging to the previous log file if no filename is given. The -d option
 disables logging. If the $> dcmd is used, logging is enabled if a filename argument
 is specified; otherwise, logging is disabled. If the specified log file already exists,
 mdb appends any new log output to the file.

::map command
 Map the value of dot to a corresponding value using the command specified as a
 string argument, and then print the new value of dot. If the command contains
 whitespace or metacharacters, it must be quoted. The ::map dcmd can be used in
 pipelines to transform the list of addresses into a new list of addresses.

[address] ::mappings [name]
[address] $m [name]
 Print a list of each mapping in the target's virtual address space, including the
 address, size, and description of each mapping. If the dcmd is preceded by an
 address, mdb will only show the mapping that contains the given address. If a string
 name argument is given, mdb will only show the mapping matching that
 description.

::next [SIG]
:e [SIG]
 Step the target program one instruction, but step over subroutine calls. If an
 optional signal name or number (see signal(3HEAD)) is specified as an argument,
 the signal is immediately delivered to the target as part of resuming its execution. If
 no target program is currently running, ::next will start a new program running
 as if by ::run and stop at the first instruction.

[address] ::nm [-DPdghnopuvx] [-t types]
[-f format] [object]
 Print the symbol tables associated with the current target. If an optional address
 preceding the dcmd is specified, only the symbol table entry for the symbol
 corresponding to address is displayed. If an object is specified, only the symbol table
 for this load object is displayed. The ::nm dcmd also recognizes the following
 options:

 -D Prints .dynsym (dynamic symbol table) instead of
 .symtab.
```

|                                         |                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -P                                      | Prints the private symbol table instead of <code>.symtab</code> .                                                                                                                                                                                                                                                                                                                      |
| -d                                      | Prints value and size fields in decimal.                                                                                                                                                                                                                                                                                                                                               |
| -g                                      | Prints only global symbols.                                                                                                                                                                                                                                                                                                                                                            |
| -h                                      | Suppresses the header line.                                                                                                                                                                                                                                                                                                                                                            |
| -n                                      | Sorts symbols by name.                                                                                                                                                                                                                                                                                                                                                                 |
| -o                                      | Prints value and size fields in octal.                                                                                                                                                                                                                                                                                                                                                 |
| -p                                      | Prints symbols as a series of <code>: :nmadd</code> commands. This option can be used with <code>-P</code> to produce a macro file that can be subsequently read into the debugger with <code>\$&lt;</code> .                                                                                                                                                                          |
| -u                                      | Prints only undefined symbols.                                                                                                                                                                                                                                                                                                                                                         |
| -v                                      | Sorts symbols by value.                                                                                                                                                                                                                                                                                                                                                                |
| -x                                      | Prints value and size fields in hexadecimal.                                                                                                                                                                                                                                                                                                                                           |
| -t <i>type</i> [, <i>type</i> ... ]     | Prints only symbols of the specified type(s). The valid <i>type</i> argument strings are: <ul style="list-style-type: none"> <li>noty     STT_NOTYPE</li> <li>objt     STT_OBJECT</li> <li>func     STT_FUNC</li> <li>sect     STT_SECTION</li> <li>file     STT_FILE</li> <li>comm     STT_COMMON</li> <li>tls      STT_TLS</li> <li>regi     STT_SPARC_REGISTER</li> </ul>           |
| -f <i>format</i> [, <i>format</i> ... ] | Prints only the specified symbol information. The valid <i>format</i> argument strings are: <ul style="list-style-type: none"> <li>ndx      symbol table index</li> <li>val      symbol value</li> <li>size     size in bytes</li> <li>type     symbol type</li> <li>bind     binding</li> <li>oth      other</li> <li>shndx    section index</li> <li>name     symbol name</li> </ul> |

mdb(1)

```

 ctype C type for symbol (if known)
 obj object which defines symbol
value : :nmadd [-fo] [-e end] [-s size] name
Add the specified symbol name to the private symbol table. mdb provides a private,
configurable symbol table that can be used to interpose on the target's symbol table,
as described under Symbol Name Resolution above. The : :nmadd dcmd also
recognizes the following options:
 -e Sets the size of the symbol to end - value.
 -f Sets the type of the symbol to STT_FUNC.
 -o Sets the type of the symbol to STT_OBJECT.
 -s Sets the size of the symbol to size.
: :nmdel name
Delete the specified symbol name from the private symbol table.
: :objects
Print a map of the target's virtual address space, showing only those mappings that
correspond to the primary mapping (usually the text section) of each of the known
load objects.
: :offsetof type member
Print the offset of the specified member of the specified type. The type should be the
name of a C structure. The offset is printed in bytes, unless the member is a
bit-field, in which case the offset may be printed in bits. The output is always
suffixed with the appropriate units for clarity. The type name may use the
backquote (`) scoping operator described under Symbol Name Resolution,
above. The : :offsetof dcmd may only be used with objects that contain
symbolic debugging information designed for use with mdb. Refer to NOTES,
Symbolic Debugging Information, below for more information.
address : :print [-aCdLptx] [-c lim]
[-l lim] [type [member ...]]
Print the data structure at the specified virtual address using the given type
information. The type parameter may name a C struct, union, enum, fundamental
integer type, or a pointer to any of these types. If the type name contains
whitespace (for example, "struct foo"), it must be enclosed in single or double
quotes. The type name may use the backquote (`) scoping operator described
under Symbol Name Resolution, above. If the type is a structured type, the
: :print dcmd will recursively print each member of the struct or union. If the
type argument is not present and a static or global STT_OBJECT symbol matches
the address, : :print will infer the appropriate type automatically. If the type
argument is specified, it may be followed by an optional list of member expressions,
in which case only those members and submembers of the specified type are
displayed. If type contains other structured types, each member string may refer to
a sub-structure element by forming a list of member names separated by period
(.) delimiters. The : :print dcmd may only be used with objects that contain
symbolic debugging information designed for use with mdb. Refer to NOTES,
```

Symbolic Debugging Information, below for more information. After displaying the data structure, `::print` increments dot by the size of *type* in bytes.

If the `-a` option is present, the address of each member is displayed. If the `-p` option is present, `::print` interprets *address* as a physical memory address instead of a virtual memory address. If the `-t` option is present, the type of each member is displayed. If the `-d` or `-x` options are present, all integers are displayed in decimal (`-d`) or hexadecimal (`-x`). By default, a heuristic is used to determine if the value should be displayed in decimal or hexadecimal. The number of characters in a character array that will be read and displayed as a string can be limited with the `-c` option. If the `-C` option is present, no limit is enforced. The number of elements in a standard array that will be read and displayed can be limited with the `-l` option. If the `-L` option is present, no limit is enforced and all array elements are shown. The default values for `-c` and `-l` can be modified using `::set` or the `-o` command-line option as described under **OPTIONS**, below.

`::quit`

`$q`

Quit the debugger.

`[ thread ] ::regs`

`[ thread ] $r`

Print the general purpose register set of the representative thread. If a thread is specified, the general purpose register set of that thread is displayed. The thread expression should be one of the thread identifiers described under **Thread Support**, above.

`::release [ -a ]`

`:R [ -a ]`

Release the previously attached process or core file. If the `-a` option is present, the process is released and left stopped and abandoned. It can subsequently be continued by `prun(1)` (see `proc(1)`) or it can be resumed by applying `mdb` or another debugger. By default, a released process is forcibly terminated if it was created by `mdb` using `::run`, or it is released and set running if it was attached to by `mdb` using the `-p` option or using the `::attach` or `:A` dcmds.

`::run [ args ... ]`

`:r [ args ... ]`

Start a new target program running with the specified arguments and attach to it. The arguments are not interpreted by the shell. If the debugger is already examining a live running program, it will first detach from this program as if by `::release`.

`::set [ -wF ] [ +/-o option ] [ -s distance ] [ -I path ]`

`[ -L path ] [ -P prompt ]`

Get or set miscellaneous debugger properties. If no options are specified, the current set of debugger properties is displayed. The `::set` dcmd recognizes the following options:

`-F` Forcibly takes over the next user process that `::attach` is applied to, as if `mdb` had been executed with the `-F` option on the command line.

## mdb(1)

**-I** Sets the default path for locating macro files. The path argument may contain any of the special tokens described for the **-I** command-line option under **OPTIONS** below.

**-L** Sets the default path for locating debugger modules. The path argument may contain any of the special tokens described for the **-I** command-line option under **OPTIONS** below.

**-o** Enables the specified debugger option. If the **+o** form is used, the option is disabled. The option strings are described along with the **-o** command-line option under **OPTIONS** below.

**-P** Sets the command prompt to the specified prompt string.

**-s** Sets the symbol matching distance to the specified distance. Refer to the description of the **-s** command-line option under **OPTIONS** below for more information.

**-w** Re-opens the target for writing, as if **mdb** had been executed with the **-w** option on the command line.

**[signal] ::sigbp [+/-dDestT] [-c cmd] [-n count] SIG ...**  
**[signal] :t [+/-dDestT] [-c cmd] [-n count] SIG ...**  
Trace delivery of the specified signals. The signals are identified using an optional signal number preceding the **dcmd**, or a list of signal names or numbers (see **signal(3HEAD)**) following the **dcmd**. The **-d**, **-D**, **-e**, **-s**, **-t**, **-T**, **-c**, and **-n** options have the same meaning as they do for the **::evset dcmd**. Initially, the set of signals that cause the process to dump core by default (see **signal(3HEAD)**) and **SIGINT** are traced.

**::sizeof type**  
Print the size of the specified *type* in bytes. The *type* parameter may name a C struct, union, enum, fundamental integer type, or a pointer to any of these types. The type name may use the backquote (``) scoping operator described under **Symbol Name Resolution**, above. The **::sizeof dcmd** may only be used with objects that contain symbolic debugging information designed for use with **mdb**. Refer to **NOTES, Symbolic Debugging Information**, below for more information.

**[ address ] ::stack [ count ]**  
**[ address ] \$c [ count ]**  
Print a C stack backtrace. If the **dcmd** is preceded by an explicit *address*, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than *count* arguments are displayed for each stack frame in the output.

**::status**  
Print a summary of information related to the current target.

**::step [ over | out ] [ SIG ]**  
**:s [ SIG ]**  
**:u [ SIG ]**

Step the target program one instruction. If an optional signal name or number (see `signal(3HEAD)`) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If the optional "over" argument is specified, `::step` will step over subroutine calls. The `::step over` argument is the same as the `::next` dcmd. If the optional "out" argument is specified, the target program will continue until the representative thread returns from the current function. If no target program is currently running, `::step out` will start a new program running as if by `::run` and stop at the first instruction. The `::s` dcmd is the same as `::step`. The `::u` dcmd is the same as `::step out`.

`[ syscall ] ::sysbp [ +/-dDestT ] [ -io ] [ -c cmd ]  
[ -n count ] syscall...`

Trace entry to or exit from the specified system calls. The system calls are identified using an optional system call number preceding the dcmd, or a list of system call names or numbers (see `<sys/syscall.h>`) following the dcmd. If the `-i` option is specified (the default), the event specifiers trigger on entry into the kernel for each system call. If the `-o` option is specified, the event specifiers trigger on exit out from the kernel. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset` dcmd.

`thread ::tls symbol`

Print the address of the storage for the specified thread-local storage (TLS) symbol in the context of the specified thread. The thread expression should be one of the thread identifiers described under `Thread Support`, above. The symbol name may use any of the scoping operators described under `Symbol Name Resolution`, above.

`::typeset [ +/-t ] variable-name ...`

Set attributes for named variables. If one or more variable names are specified, they are defined and set to the value of dot. If the `-t` option is present, the user-defined tag associated with each variable is set. If the `+t` option is present, the tag is cleared. If no variable names are specified, the list of variables and their values is printed.

`::unload module-name`

Unload the specified dmod. The list of active dmods may be printed using the `::dmods` dcmd. Built-in modules may not be unloaded. Modules that are busy (that is, provide dcmds that are currently executing) may not be unloaded.

`::unset variable-name ...`

Unset (remove) the specified variable(s) from the list of defined variables. Some variables exported by `mdb` are marked as persistent, and may not be unset by the user.

`::vars [ -npt ]`

Print a listing of named variables. If the `-n` option is present, the output is restricted to variables that currently have non-zero values. If the `-p` option is present, the variables are printed in a form suitable for re-processing by the debugger using the `$<` dcmd. This option can be used to record the variables to a

## mdb(1)

macro file and then restore these values later. If the `-t` option is present, only the tagged variables are printed. Variables can be tagged using the `-t` option of the `::typeset dcmd`.

`::version`

Print the debugger version number.

`address ::vtop [-a as]`

Print the physical address mapping for the specified virtual address, if possible.

The `::vtop dcmd` is only available when examining a kernel target, or when examining a user process inside a kernel crash dump (after a `::context dcmd` has been issued).

When examining a kernel target from the kernel context, the `-a` option can be used to specify the address (*as*) of an alternate address space structure that should be used for the virtual to physical translation. By default, the kernel's address space is used for translation. This option is available for active address spaces even when the dump content only contains kernel pages.

`[ address ] ::walk walker-name [ variable-name ]`

Walk through the elements of a data structure using the specified walker. The available walkers can be listed using the `::walkers dcmd`. Some walkers operate on a global data structure and do not require a starting address. For example, walk the list of proc structures in the kernel. Other walkers operate on a specific data structure whose address must be specified explicitly. For example, given a pointer to an address space, walk the list of segments. When used interactively, the `::walk dcmd` will print the address of each element of the data structure in the default base. The dcmd can also be used to provide a list of addresses for a pipeline. The walker name may use the backquote (```) scoping operator described under `dcmd` and `Walker Name Resolution`, above. If the optional *variable-name* is specified, the specified variable will be assigned the value returned at each step of the walk when `mdb` invokes the next stage of the pipeline.

`::walkers`

List the available walkers and print a brief description for each one.

`::whence [-v] name ...`

`::which [-v] name ...`

Print the dmod that exports the specified dcmds and walkers. These dcmds can be used to determine which dmod is currently providing the global definition of the given dcmd or walker. Refer to the section on `dcmd` and `Walker Name Resolution` above for more information on global name resolution. The `-v` option will cause the dcmd to print the alternate definitions of each dcmd and walker in order of precedence.

`addr [ ,len ] ::wp [ +/- -dDestT ] [ -rwx ] [ -c cmd ] [ -n count ]`

`addr [ ,len ] :a [ cmd ... ]`

`addr [ ,len ] :p [ cmd ... ]`

`addr [ ,len ] :w [ cmd ... ]`

Set a watchpoint at the specified address. The length in bytes of the watched region may be set by specifying an optional repeat count preceding the dcmd. If no length

is explicitly set, the default is one byte. The `:wp dcmd` allows the watchpoint to be configured to trigger on any combination of read (`-r` option), write (`-w` option), or execute (`-x` option) access. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `:evset dcmd`. The `:a dcmd` sets a read access watchpoint at the specified address. The `:p dcmd` sets an execute access watchpoint at the specified address. The `:w dcmd` sets a write access watchpoint at the specified address. The arguments following the `:a`, `:p`, and `:w` dcms are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

`::xdata`

List the external data buffers exported by the current target. External data buffers represent information associated with the target that can not be accessed through standard target facilities (that is, an address space, symbol table, or register set). These buffers may be consumed by dcms; for more information, refer to the *Solaris Modular Debugger Guide*.

`:z`

Delete all event specifiers from the list of traced software events. Event specifiers can also be deleted using `::delete`.

**OPTIONS** The following options are supported:

- `-A` Disables automatic loading of mdb modules. By default, mdb attempts to load debugger modules corresponding to the active shared libraries in a user process or core file, or to the loaded kernel modules in the live operating system or an operating system crash dump.
- `-f` Forces raw file debugging mode. By default, mdb attempts to infer whether the object and core file operands refer to a user executable and core dump or to a pair of operating system crash dump files. If the file type cannot be inferred, the debugger will default to examining the files as plain binary data. The `-f` option forces mdb to interpret the arguments as a set of raw files to examine.
- `-F` Forcibly takes over the specified user process, if necessary. By default, mdb refuses to attach to a user process that is already under the control of another debugging tool, such as `truss(1)`. With the `-F` option, mdb attaches to these processes anyway. This may produce unexpected interactions between mdb and the other tools attempting to control the process.
- `-I path` Sets default path for locating macro files. Macro files are read using the `$<` or `$<<` dcms. The path is a sequence of directory names delimited by colon (`:`) characters. The `-I include path` and `-L library path` (see below) may also contain any of the following tokens:
  - `%i` Expands to the current instruction set architecture (ISA) name ('sparc', 'sparcv9', or 'i386').

## mdb(1)

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p><code>%o</code> Expands to the old value of the path being modified. This is useful for appending or prepending directories to an existing path.</p> <p><code>%p</code> Expands to the current platform string (either <code>uname -i</code> or the platform string stored in the process core file or crash dump).</p> <p><code>%r</code> Expands to the pathname of the root directory. An alternate root directory may be specified using the <code>-R</code> option. If no <code>-R</code> option is present, the root directory is derived dynamically from the path to the <code>mdb</code> executable itself. For example, if <code>/bin/mdb</code> is executed, the root directory will be <code>.</code>. If <code>/net/hostname/bin/mdb</code> were executed, the root directory would be derived as <code>/net/hostname</code>.</p> <p><code>%t</code> Expands to the name of the current target. This will either be the literal string <code>'proc'</code> (a user process or user process core file), <code>'kvm'</code> (a kernel crash dump or the live operating system), or <code>'raw'</code> (a raw file).</p> |
|                      | <p>The default include path for 32-bit <code>mdb</code> is:</p> <pre>%r/usr/platform/%p/lib/adb:%r/usr/lib/adb</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                      | <p>The default include path for 64-bit <code>mdb</code> is:</p> <pre>%r/usr/platform/%p/lib/adb/%i:%r/usr/lib/adb/%i</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-k</code>      | <p>Forces kernel debugging mode. By default, <code>mdb</code> attempts to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The <code>-k</code> option forces <code>mdb</code> to assume these files are operating system crash dump files. If no object or core operand is specified, but the <code>-k</code> option is specified, <code>mdb</code> defaults to an object file of <code>/dev/ksyms</code> and a core file of <code>/dev/kmem</code>. Access to <code>/dev/kmem</code> is restricted to group <code>sys</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-L path</code> | <p>Sets default path for locating debugger modules. Modules are loaded automatically on startup or using the <code>:::load dcmd</code>. The <code>path</code> is a sequence of directory names delimited by colon (<code>:</code>) characters. The <code>-L</code> library path may also contain any of the tokens shown for <code>-I</code> above.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-m</code>      | <p>Disables demand-loading of kernel module symbols. By default, <code>mdb</code> processes the list of loaded kernel modules and performs demand loading of per-module symbol tables. If the <code>-m</code> option is specified, <code>mdb</code> will not attempt to process the kernel module list or</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

provide per-module symbol tables. As a result, `mdb` modules corresponding to active kernel modules will not be loaded on startup.

`-M` Preloads all kernel module symbols. By default, `mdb` performs demand-loading for kernel module symbols: the complete symbol table for a module is read when an address in that module's text or data section is referenced. With the `-M` option, `mdb` loads the complete symbol table of all kernel modules during startup.

`-o option` Enables the specified debugger option. If the `+o` form of the option is used, the specified *option* is disabled. Unless noted below, each option is off by default. `mdb` recognizes the following *option* arguments:

`adb`

Enables stricter `adb(1)` compatibility. The prompt will be set to the empty string and many `mdb` features, such as the output pager, will be disabled.

`array_mem_limit=limit`

Sets the default limit on the number of array members that `::print` will display. If *limit* is the special token `none`, all array members will be displayed by default.

`array_str_limit=limit`

Sets the default limit on the number of characters that `::print` will attempt to display as an ASCII string when printing a char array. If *limit* is the special token `none`, the entire char array will be displayed as a string by default.

`follow_exec_mode=mode`

Sets the debugger behavior for following an `exec(2)` system call. The *mode* should be one of the following named constants:

`ask` If `stdout` is a terminal device, the debugger stops after the `exec(2)` system call has returned and then prompts the user to decide whether to follow the `exec` or stop. If `stdout` is not a terminal device, the `ask` mode defaults to `stop`.

`follow` The debugger follows the `exec` by automatically continuing the target process and resetting all of its mappings and symbol tables based on the new executable. The `follow` behavior is discussed in more detail under `NOTES, Interaction with Exec`, below.

`stop` The debugger stops following return from the `exec` system call. The `stop` behavior is discussed in more detail under `NOTES, Interaction with Exec`, below.

## mdb(1)

### `follow_fork_mode=mode`

Sets the debugger behavior for following a `fork(2)`, `fork1(2)`, or `vfork(2)` system call. The *mode* should be one of the following named constants:

- `ask` If `stdout` is a terminal device, the debugger stops after the `fork(2)` system call has returned and then prompts the user to decide whether to follow the parent or child. If `stdout` is not a terminal device, the `ask` mode defaults to `parent`.
- `parent` The debugger follows the parent process, and detaches from the child process and sets it running.
- `child` The debugger follows the child process, and detaches from the parent process and sets it running.

### `ignoreeof`

The debugger will not exit when an EOF sequence (`^D`) is entered at the terminal. The `::quit` dcmd must be used to quit.

### `nostop`

Does not stop a user process when attaching to it when the `-p` option is specified or when the `::attach` or `:A` dcmds are applied. The `nostop` behavior is described in more detail under NOTES, `Process Attach and Release`, below.

### `pager`

Enables the output pager (default).

### `repeatlast`

If a `NEWLINE` is entered as the complete command at the terminal, `mdb` repeats the previous command with the current value of `dot`. This option is implied by `-o adb`.

### `showlmid`

`mdb` provides support for symbol naming and identification in user applications that make use of link maps other than `LM_ID_BASE` and `LM_ID_LDSO`, as described in `Symbol Name Resolution`, above. Symbols on link maps other than `LM_ID_BASE` or `LM_ID_LDSO` will be shown as `LMlmid`library`symbol`, where `lmid` is the link-map ID in the default output radix (16). The user may optionally configure `mdb` to show the link-map ID scope of all symbols and objects, including those associated with `LM_ID_BASE` and `LM_ID_LDSO`, by enabling the `showlmid` option. Built-in dcmds that deal with object file names will display link-map IDs according to the value of `showlmid` above, including `::nm`, `::mappings`, `$m`, and `::objects`.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-p <i>pid</i></code>      | Attaches to and stops the specified process-id. <code>mdb</code> will use the <code>/proc/<i>pid</i>/object/a.out</code> file as the executable file pathname.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-P <i>prompt</i></code>   | Sets the command prompt. The default prompt is <code>'&gt;'</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>-R <i>root</i></code>     | Sets root directory for pathname expansion. By default, the root directory is derived from the pathname of the <code>mdb</code> executable itself. The root directory is substituted in place of the <code>%r</code> token during pathname expansion.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-s <i>distance</i></code> | Sets the symbol matching distance for address-to-symbol-name conversions to the specified <i>distance</i> . By default, <code>mdb</code> sets the distance to zero, which enables a smart-matching mode. Each ELF symbol table entry includes a value <i>V</i> and size <i>S</i> , representing the size of the function or data object in bytes. In smart mode, <code>mdb</code> matches an address <i>A</i> with the given symbol if <i>A</i> is in the range [ <i>V</i> , <i>V</i> + <i>S</i> ). If any non-zero distance is specified, the same algorithm is used, but <i>S</i> in the expression above is always the specified absolute distance and the symbol size is ignored. |
| <code>-S</code>                 | Suppresses processing of the user's <code>~/ .mdbContext</code> file. By default, <code>mdb</code> reads and processes the macro file <code>.mdbContext</code> if one is present in the user's home directory, as defined by <code>\$HOME</code> . If the <code>-S</code> option is present, this file will not be read.                                                                                                                                                                                                                                                                                                                                                              |
| <code>-u</code>                 | Forces user debugging mode. By default, <code>mdb</code> attempts to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The <code>-u</code> option forces <code>mdb</code> to assume these files are not operating system crash dump files.                                                                                                                                                                                                                                                                                                                                                 |
| <code>-V <i>version</i></code>  | Sets disassembler version. By default, <code>mdb</code> attempts to infer the appropriate disassembler version for the debug target. The disassembler can be set explicitly using the <code>-V</code> option. The <code>::disasms dcmd</code> lists the available disassembler versions.                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-w</code>                 | Opens the specified object and core files for writing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-y</code>                 | Sends explicit terminal initialization sequences for tty mode. Some terminals, such as <code>cmdt001(1)</code> , require explicit initialization sequences to switch into a tty mode. Without this initialization sequence, terminal features such as standout mode may not be available to <code>mdb</code> .                                                                                                                                                                                                                                                                                                                                                                        |

## OPERANDS

The following operands are supported:

|               |                                                                                                                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>object</i> | Specifies an ELF format object file to examine. <code>mdb</code> provides the ability to examine and edit ELF format executables ( <code>ET_EXEC</code> ), ELF dynamic library files ( <code>ET_DYN</code> ), ELF relocatable object files ( <code>ET_REL</code> ), and operating system <code>unix.X</code> symbol table files. |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## mdb(1)

|                              |                                 |                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <i>core</i>                     | Specifies an ELF process core file (ET_CORE), or an operating system crash dump vmcore.X file. If an ELF core file operand is provided without a corresponding object file, mdb will attempt to infer the name of the executable file that produced the core using several different algorithms. If no executable is found, mdb will still execute, but some symbol information may be unavailable. |
|                              | <i>suffix</i>                   | Specifies the numerical suffix representing a pair of operating system crash dump files. For example, if the suffix is '3', mdb infers that it should examine the files 'unix.3' and 'vmcore.3'. The string of digits will not be interpreted as a suffix if an actual file of the same name is present in the current directory.                                                                   |
| <b>USAGE</b>                 |                                 | mdb processes all input files (including scripts, object files, core files, and raw data files) in a large file aware fashion. See <code>largefile(5)</code> for more information about the processing of large files, which are files greater than or equal to 2 Gbytes (2 <sup>31</sup> bytes).                                                                                                   |
| <b>EXIT STATUS</b>           |                                 | The following exit values are returned:<br>0           Debugger completed execution successfully.<br>1           A fatal error occurred.<br>2           Invalid command line options were specified.                                                                                                                                                                                                |
| <b>ENVIRONMENT VARIABLES</b> | <i>HISTSIZE</i>                 | This variable is used to determine the maximum length of the command history list. If this variable is not present, the default length is 128.                                                                                                                                                                                                                                                      |
|                              | <i>HOME</i>                     | This variable is used to determine the pathname of the user's home directory, where a <code>.mdbContext</code> file may reside. If this variable is not present, no <code>.mdbContext</code> processing will occur.                                                                                                                                                                                 |
|                              | <i>SHELL</i>                    | This variable is used to determine the pathname of the shell used to process shell escapes requested using the <code>!</code> meta-character. If this variable is not present, <code>/bin/sh</code> is used.                                                                                                                                                                                        |
| <b>FILES</b>                 | <code>\$HOME/.mdbContext</code> | User mdb initialization file. The <code>.mdbContext</code> file, if present, is processed after the debug target has been initialized, but before module auto-loading is performed or any commands have been read from standard input.                                                                                                                                                              |
|                              | <code>/dev/kmem</code>          | Kernel virtual memory image device. This device special file is used as the core file when examining the live operating system.                                                                                                                                                                                                                                                                     |
|                              | <code>/dev/ksyms</code>         | Kernel symbol table device. This device special file is used as the object file when examining the live operating system.                                                                                                                                                                                                                                                                           |
|                              | <code>/proc/pid/*</code>        | Process information files that are read when examining and controlling user processes.                                                                                                                                                                                                                                                                                                              |

/usr/lib/adb

/usr/platform/*platform-name*/lib/adb

Default directories for macro files that are read with the `$<` and `$<<` dcmds.

*platform-name* is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see `uname(1)`).

/usr/lib/mdb

/usr/platform/*platform-name*/lib/mdb

Default directories for debugger modules that are loaded using the `: :load` dcmd.

*platform-name* is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see `uname(1)`).

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                       |
|---------------------|---------------------------------------|
| Availability        | SUNWmdb (32-bit)<br>SUNWmdbx (64-bit) |
| Interface Stability | Evolving                              |

*Linker and Libraries Guide*

*Solaris Modular Debugger Guide*

**Use of the Error Recovery Mechanism**

The debugger and its dmods execute in the same address space, and thus it is quite possible that a buggy dmod can cause `mdb` to dump core or otherwise misbehave. The `mdb` resume capability, described above under `Signal Handling`, provides a limited recovery mechanism for these situations. However, it is not possible for `mdb` to know definitively whether the dmod in question has corrupted only its own state, or the debugger's global state. Therefore a resume operation cannot be guaranteed to be safe, or to prevent a subsequent crash of the debugger. The safest course of action following a resume is to save any important debug information, and then quit and restart the debugger.

**Use of the Debugger to Modify the Live Operating System**

The use of the debugger to modify (that is, write to) the address space of live running operating system is extremely dangerous, and may result in a system panic in the event the user damages a kernel data structure.

mdb(1)

**Limitations on Examining Process Core Files**

mdb does not provide support for examining process core files that were generated by a release of Solaris preceding Solaris 2.6. If a core file from one operating system release is examined on a different operating system release, the run-time link-editor debugging interface (`librtld_db`) may not be able to initialize. In this case, symbol information for shared libraries will not be available. Furthermore, since shared mappings are not present in user core files, the text section and read-only data of shared libraries may not match the data that was present in the process at the time it dumped core. Core files from Solaris Intel systems may not be examined on Solaris SPARC systems, and vice-versa.

**Limitations on Examining Crash Dump Files**

Crash dumps from Solaris 7 and earlier releases may only be examined with the aid of the `libkvm` from the corresponding operating system release. If a crash dump from one operating system release is examined using the `dmods` from a different operating system release, changes in the kernel implementation may prevent some `dcmds` or `walkers` from working properly. `mdb` will issue a warning message if it detects this condition. Crash dumps from Solaris Intel systems may not be examined on Solaris SPARC systems, and vice-versa.

**Relationship Between 32-bit and 64-bit Debugger**

`mdb` provides support for debugging both 32-bit and 64-bit programs. Once it has examined the target and determined its data model, `mdb` automatically re-executes the `mdb` binary that has the same data model as the target, if necessary. This approach simplifies the task of writing debugger modules, because the modules that are loaded will use the same data model as the primary target. Only the 64-bit debugger may be used to debug 64-bit target programs. The 64-bit debugger can only be used on a system that is running the 64-bit operating environment.

The debugger may also need to re-execute itself when debugging a 32-bit process that execs a 64-bit process, or vice-versa. The handling of this situation is discussed in more detail under `Interaction with Exec`, below.

**Interaction with Exec**

When a controlled process performs a successful `exec(2)`, the behavior of the debugger is controlled by the `::set -o follow_exec_mode` option, as described above. If the debugger and victim process have the same data model, then the `"stop"` and `"follow"` modes determine whether `mdb` automatically continues the target or returns to the debugger prompt following the `exec`. If the debugger and victim process have a different data model, then the `"follow"` behavior causes `mdb` to automatically re-exec the `mdb` binary with the appropriate data model and to re-attach to the process, still stopped on return from the `exec`. Not all debugger state is preserved across this re-exec.

If a 32-bit victim process execs a 64-bit program, then `"stop"` returns to the command prompt, but the debugger is no longer able to examine the process because it is now using the 64-bit data model. To resume debugging, execute the `::release -a dcmd`, quit `mdb`, and then execute `mdb -p pid` to re-attach the 64-bit debugger to the process.

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interaction with Job Control</b>   | <p>If a 64-bit victim process execs a 32-bit program, then "stop" will return to the command prompt, but the debugger will only provide limited capabilities for examining the new process. All built-in dcmds will work as advertised, but loadable dcmds will not since they do not perform data model conversion of structures. The user should release and re-attach the debugger to the process as described above in order to restore full debugging capabilities.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Process Attach and Release</b>     | <p>If the debugger is attached to a process that is stopped by job control (that is, it stopped in response to SIGTSTP, SIGTTIN, or SIGTTOU), the process may not be able to be set running again when it is continued by a continue dcmd. If the victim process is a member of the same session (that is, it shares the same controlling terminal as mdb), mdb attempts to bring the associated process group to the foreground and to continue the process with SIGCONT to resume it from job control stop. When mdb is detached from such a process, it restores the process group to the background before exiting. If the victim process is not a member of the same session, mdb cannot safely bring the process group to the foreground, so it continues the process with respect to the debugger, but the process remains stopped by job control. mdb prints a warning in this case, and the user must issue an "fg" command from the appropriate shell in order to resume the process.</p> |
| <b>Process Attach and Release</b>     | <p>When mdb attaches to a running process, the process is stopped and remains stopped until one of the continue dcmds is applied, or the debugger quits. If the -o nostop option is enabled prior to attaching the debugger to a process with -p, or prior to issuing an ::attach or :A command, mdb attaches to the process but does not stop it. While the process is still running, it may be inspected as usual (albeit with inconsistent results) and breakpoints or other tracing flags may be enabled. If the :c or ::cont dcmds are executed while the process is running, the debugger waits for the process to stop. If no traced software events occur, the user can send an interrupt (^C) after :c or ::cont to force the process to stop and return control to the debugger.</p>                                                                                                                                                                                                      |
| <b>Symbolic Debugging Information</b> | <p>mdb releases the current running process (if any) when the :R, ::release, :r, ::run, \$q, or ::quit dcmds are executed, or when the debugger terminates as the result of an EOF or signal. If the process was originally created by the debugger using :r or ::run, it will be forcibly terminated as if by SIGKILL when it is released. If the process was already running prior to attaching mdb to it, it will be set running again when it is released. A process may be released and left stopped and abandoned using the ::release -a option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Symbolic Debugging Information</b> | <p>The ::list, ::offsetof, ::print, and ::sizeof dcmds require that one or more load objects contain compressed symbolic debugging information suitable for use with mdb. This information is currently only available for certain Solaris kernel modules.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Developer Information</b>          | <p>The <i>Solaris Modular Debugger Guide</i> provides a more detailed description of mdb features, as well as information for debugger module developers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Developer Information</b>          | <p>The header file &lt;sys/mdb_modapi.h&gt; contains prototypes for the functions in the MDB Module API, and the SUNWmdbdm package provides source code for an example module in the directory /usr/demo/mdb.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## mesg(1)

| <b>NAME</b>                  | mesg – permit or deny messages                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |                     |          |

| <b>SYNOPSIS</b>              | <b>mesg</b> [-n   -y   n   y]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |                     |          |
| <b>DESCRIPTION</b>           | The <b>mesg</b> utility will control whether other users are allowed to send messages via <b>write(1)</b> , <b>talk(1)</b> , or other utilities to a terminal device. The terminal device affected is determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, <b>mesg</b> reports the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state. |                |                 |              |         |                     |          |
| <b>OPTIONS</b>               | The following options are supported:<br><br>-n   n      Denies permission to other users to send message to the terminal. See <b>write(1)</b> .<br><br>-y   y      Grants permission to other users to send messages to the terminal.                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |                     |          |
| <b>ENVIRONMENT VARIABLES</b> | See <b>environ(5)</b> for descriptions of the following environment variables that affect the execution of <b>mesg</b> : <b>LANG</b> , <b>LC_ALL</b> , <b>LC_CTYPE</b> , <b>LC_MESSAGES</b> , and <b>NLSPATH</b> .                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |                     |          |
| <b>EXIT STATUS</b>           | The following exit values are returned:<br><br>0            if messages are receivable.<br><br>1            if messages are not receivable.<br><br>2            on error.                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |                     |          |

| DESCRIPTION | <p>The <code>message</code> command puts <i>string</i> out on the FMLI message line. If there is no <i>string</i>, the <i>stdin</i> input to <code>message</code> will be used. The output of <code>message</code> has a duration (length of time it remains on the message line). The default duration is "transient": it or one of two other durations can be requested with the mutually-exclusive options below.</p> <p>Messages displayed with <code>message -p</code> will replace (change the value of) any message currently displayed or stored via use of the <code>permanentmsg</code> descriptor. Likewise, <code>message -f</code> will replace any message currently displayed or stored via use of the <code>framemsg</code> descriptor. If more than one message in a frame definition file is specified with the <code>-p</code> option, the last one specified will be the permanent duration message.</p> <p>The <i>string</i> argument should always be the last argument.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| OPTIONS     | <ul style="list-style-type: none"> <li>-t        Explicitly defines a message to have transient duration. Transient messages remain on the message line only until the user presses another key or a CHECKWORLD occurs. The descriptors <code>itemmsg</code> , <code>fieldmsg</code> , <code>invalidmsg</code> , <code>choicemsg</code> , the default-if-not-defined value of <code>oninterrupt</code> , and FMLI generated error messages (that is, from syntax errors) also output transient duration messages. Transient messages take precedence over both frame messages and permanent messages.</li> <li>-f        Defines a message to have "frame" duration. Frame messages remain on the message line as long as the frame in which they are defined is current. The descriptor <code>framemsg</code> also outputs a frame duration message. Frame messages take precedence over permanent messages.</li> <li>-p        Defines a message to have "permanent" duration. Permanent messages remain on the message line for the length of the FMLI session, unless explicitly replaced by another permanent message or temporarily superseded by a transient message or frame message. A permanent message is not affected by navigating away from, or by closing, the frame which generated the permanent message. The descriptor <code>permanentmsg</code> also outputs a permanent duration message.</li> <li>-b<i>num</i>   Rings the terminal bell <i>num</i> times, where <i>num</i> is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen will flash <i>num</i> times instead, if possible.</li> <li>-o        Forces <code>message</code> to duplicate its message to <i>stdout</i> .</li> <li>-w        Turns on the working indicator.</li> </ul> |

## message(1F)

### EXAMPLES

**EXAMPLE 1** A sample output of message on the message line:

When a value entered in a field is invalid, ring the bell 3 times and then display Invalid Entry: Try again! on the message line:

```
invalidmsg=`message -b 3 "Invalid Entry: Try again!"`
```

Display a message that tells the user what is being done:

```
done=`message EDITOR has been set in your environment` close
```

Display a message on the message line and *stdout* for each field in a form (a pseudo-"field duration" message).

```
fieldmsg=`message -o -f "Enter a filename."`
```

Display a blank transient message (effect is to "remove" a permanent or frame duration message).

```
done=`message "" nop
```

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

### SEE ALSO

`sleep(1)`, `attributes(5)`

### NOTES

If `message` is coded more than once on a single line, it may appear that only the right-most instance is interpreted and displayed. Use `sleep(1)` between uses of `message` in this case, to display multiple messages.

`message -f` should not be used in a stand-alone backquoted expression or with the `init` descriptor because the frame is not yet current when these are evaluated.

In cases where ``message -f "string" `` is part of a stand-alone backquoted expression, the context for evaluation of the expression is the previously current frame. The previously current frame can be the frame that issued the `open` command for the frame containing the backquoted expression, or it can be a frame given as an argument when `fml i` was invoked. That is, the previously current frame is the one whose frame message will be modified.

Permanent duration messages are displayed when the user navigates to the command line.

| <b>SYNOPSIS</b>              | <code>/usr/sbin/mixerctl [-a   -d <i>dev</i>] [-iv] [-e   -o]</code>                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b>           | Some audio devices support the audio mixer functionality. See <code>mixer(7I)</code> for a complete description of the audio mixer. The <code>mixerctl</code> command is used to control the mode of the audio mixer and to get information about the audio mixer and the audio device. See <code>audio(7I)</code> for details. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>               | The following options are supported. If none are specified, option <code>-i</code> is assumed:                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                              | <code>-a</code>                                                                                                                                                                                                                                                                                                                 | The command applies to all audio devices.                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                              | <code>-e</code>                                                                                                                                                                                                                                                                                                                 | Enables the audio mixer function if the audio device supports it. If supported, the audio mixer may be enabled at any time. The command silently ignores the enable option if the audio mixer is already enabled.                                                                                                                                                                                                                                                                |
|                              | <code>-i</code>                                                                                                                                                                                                                                                                                                                 | Prints the audio device type information for the device and indicates whether the audio device uses the audio mixer. If the device does use the audio mixer, this option displays the audio mixer's mode.                                                                                                                                                                                                                                                                        |
|                              | <code>-o</code>                                                                                                                                                                                                                                                                                                                 | Turns off the audio mixer function if the audio device supports it. If supported, the audio mixer may be turned off if only one process has the device opened with the <code>O_RDWR</code> flag, or, if two different processes have the device opened, one with the <code>O_RDONLY</code> flag and the other with the <code>O_WRONLY</code> flag. (See <code>open(2)</code> .) The command silently ignores the disable option if the audio mixer function is already disabled. |
|                              | <code>-v</code>                                                                                                                                                                                                                                                                                                                 | Verbose mode. Prints the <code>audio_info_t</code> structure for the device, along with the device type information. This option implies the <code>-i</code> option.                                                                                                                                                                                                                                                                                                             |
| <b>ENVIRONMENT VARIABLES</b> | AUDIODEV                                                                                                                                                                                                                                                                                                                        | If the <code>-d</code> and <code>-a</code> options are not specified, the AUDIODEV environment variable is consulted. If set, AUDIODEV will contain the full path name of the user's default audio device. The default audio device will be converted into a control device, and then used. If the AUDIODEV variable is not set, <code>/dev/audioctl</code> is used.                                                                                                             |
| <b>FILES</b>                 | <code>/dev/audioctl</code><br><br><code>/dev/sound/{0...n}ctl</code>                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>NAME</b>                  | mkdir – make directories                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>              | <b>mkdir</b> [-m <i>mode</i> ] [-p] <i>dir...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>           | <p>The <b>mkdir</b> command creates the named directories in mode 777 (possibly altered by the file mode creation mask <code>umask(1)</code>).</p> <p>Standard entries in a directory (for instance, the files “.”, for the directory itself, and “..”, for its parent) are made automatically. <b>mkdir</b> cannot create these entries by name. Creation of a directory requires write permission in the parent directory.</p> <p>The owner-ID and group-ID of the new directories are set to the process’s effective user-ID and group-ID, respectively. <b>mkdir</b> calls the <code>mkdir(2)</code> system call.</p> |
| <b>setgid and mkdir</b>      | <p>To change the <code>setgid</code> bit on a newly created directory, you must use <code>chmod g+s</code> or <code>chmod g-s</code> after executing <b>mkdir</b>.</p> <p>The <code>setgid</code> bit setting is inherited from the parent directory.</p>                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <p><code>-m mode</code>            This option allows users to specify the mode to be used for new directories. Choices for modes can be found in <code>chmod(1)</code>.</p> <p><code>-p</code>                    With this option, <b>mkdir</b> creates <i>dir</i> by creating all the non-existing parent directories first. The mode given to intermediate directories will be the difference between 777 and the bits set in the file mode creation mask. The difference, however, must be at least 300 (write and execute permission for the user).</p>                 |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <p><i>dir</i>                  A path name of a directory to be created.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of <b>mkdir</b> when encountering files greater than or equal to 2 Gbyte (2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using <b>mkdir</b></p> <p>The following example:</p> <pre>example% mkdir -p ltr/jd/jan</pre> <p>creates the subdirectory structure <code>ltr/jd/jan</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <b>mkdir</b> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <p>0                    All the specified directories were created successfully or the <code>-p</code> option was specified and all the specified directories now exist.</p>                                                                                                                                                                                                                                                                                                                                                                                               |

mkdir(1)

>0 An error occurred.

| <b>NAME</b>        | mkmsgs – create message files for use by gettext                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <b>mkmsgs</b> [-o] [-i <i>locale</i> ] <i>inputstrings</i> <i>msgfile</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>mkmsgs</code> utility is used to create a file of text strings that can be accessed using the text retrieval tools (see <code>gettext(1)</code>, <code>srchtxt(1)</code>, <code>exstr(1)</code>, and <code>gettext(3C)</code>). It will take as input a file of text strings for a particular geographic locale (see <code>setlocale(3C)</code>) and create a file of text strings in a format that can be retrieved by both <code>gettext(1)</code> and <code>gettext(3C)</code>. By using the <code>-i</code> option, you can install the created file under the <code>/usr/lib/locale/locale/LC_MESSAGES</code> directory (<code>locale</code> corresponds to the language in which the text strings are written).</p> <p><i>inputstrings</i> is the name of the file that contains the original text strings. <i>msgfile</i> is the name of the output file where <code>mkmsgs</code> writes the strings in a format that is readable by <code>gettext(1)</code> and <code>gettext(3C)</code>. The name of <i>msgfile</i> can be up to 14 characters in length, but may not contain either <code>\0</code> (null) or the ASCII code for <code>/</code> (slash) or <code>:</code> (colon).</p> <p>The input file contains a set of text strings for the particular geographic locale. Text strings are separated by a newline character. Nongraphic characters must be represented as alphabetic escape sequences. Messages are transformed and copied sequentially from <i>inputstrings</i> to <i>msgfile</i>. To generate an empty message in <i>msgfile</i>, leave an empty line at the correct place in <i>inputstrings</i>.</p> <p>Strings can be changed simply by editing the file <i>inputstrings</i>. New strings must be added only at the end of the file; then a new <i>msgfile</i> file must be created and installed in the correct place. If this procedure is not followed, the retrieval function will retrieve the wrong string and software compatibility will be broken.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-o</code> Overwrite <i>msgfile</i>, if it exists.</li> <li><code>-i locale</code> Install <i>msgfile</i> in the <code>/usr/lib/locale/locale/LC_MESSAGES</code> directory. Only someone who is super user or a member of group <code>bin</code> can create or overwrite files in this directory. Directories under <code>/usr/lib/locale</code> will be created if they do not exist.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using the <code>mkmsgs</code> command.</p> <p>The following example shows an input message source file <code>C.str</code>:</p> <pre>File %s:\t cannot be opened\n %s: Bad directory\n . . . write error\n . .</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## mkmsgs(1)

**EXAMPLE 1** Using the `mkmsgs` command. (Continued)

**EXAMPLE 2** Using Input Strings From `C.str` to Create Text Strings in a File

The following command uses the input strings from `C.str` to create text strings in the appropriate format in the file `UX` in the current directory:

```
example% mkmsgs C.str UX
```

**EXAMPLE 3** Using Input Strings From `FR.str` to Create Text Strings in a File

The following command uses the input strings from `FR.str` to create text strings in the appropriate format in the file `UX` in the directory `/usr/lib/locale/fr/LC_MESSAGES`:

```
example% mkmsgs -i fr FR.str UX
```

These text strings would be accessed if you had set the environment variable `LC_MESSAGES=fr` and then invoked one of the text retrieval tools listed at the beginning of the `DESCRIPTION` section.

**FILES** `/usr/lib/locale/locale/LC_MESSAGES/*`  
message files created by `mkmsgs`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |

**SEE ALSO** `exstr(1)`, `gettxt(1)`, `srchtxt(1)`, `gettxt(3C)`, `setlocale(3C)`, `attributes(5)`

| <b>NAME</b>        | mkstr – create an error message file by massaging C source files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/mkstr [-] messagefile prefix filename...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>mkstr</code> utility creates files of error messages. You can use <code>mkstr</code> to make programs with large numbers of error diagnostics much smaller, and to reduce system overhead in running the program — as the error messages do not have to be constantly swapped in and out.</p> <p><code>mkstr</code> processes each of the specified <i>filenames</i>, placing a massaged version of the input file in a file with a name consisting of the specified <i>prefix</i> and the original source file name. A typical example of using <code>mkstr</code> would be:</p> <pre>mkstr pistrings processed *.c</pre> <p>This command would cause all the error messages from the C source files in the current directory to be placed in the file <code>pistrings</code> and processed copies of the source for these files to be placed in files whose names are prefixed with <i>processed</i>.</p> <p>To process the error messages in the source to the message file, <code>mkstr</code> keys on the string <code>'error ('</code> in the input stream. Each time it occurs, the C string starting at the <code>'</code> is placed in the message file followed by a null character and a NEWLINE character; the null character terminates the message so it can be easily used when retrieved, the NEWLINE character makes it possible to sensibly <code>cat</code> the error message file to see its contents. The massaged copy of the input file then contains a <code>lseek</code> pointer into the file which can be used to retrieve the message, that is:</p> <pre>char efilename[ ] = "/usr/lib/pi_strings"; int efil = -1;  error(a1, a2, a3, a4) {     char     buf[256];     if (efil &lt; 0) {          efil = open(efilename, 0);         if (efil &lt; 0) { oops:             perror (efilename);             exit (1);         }     }     if (lseek(efil, (long) a1, 0)     read(efil, buf, 256) &lt;= 0)         goto oops;     printf(buf, a2, a3, a4); } </pre> |
| <b>OPTIONS</b>     | <p>– Place error messages at the end of the specified message file for recompiling part of a large <code>mkstr</code>ed program.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>                       | more, page – browse or page through a text file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>                   | <pre> /usr/bin/more [-cdflrsuw] [-lines] [+ <i>linenumber</i>] [+/<i> pattern</i>] [<i>file...</i>] /usr/bin/page [-cdflrsuw] [-lines] [+ <i>linenumber</i>] [+/<i> pattern</i>] [<i>file...</i>] /usr/xpg4/bin/more [-cdeisu] [-n <i>number</i>] [-p <i>command</i>] [-t <i>tagstring</i>]   [<i>file...</i>] /usr/xpg4/bin/more [-cdeisu] [-n <i>number</i>] [+ <i>command</i>] [-t <i>tagstring</i>]   [<i>file...</i>] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b>                | <p>The more utility is a filter that displays the contents of a text file on the terminal, one screenful at a time. It normally pauses after each screenful. <code>/usr/bin/more</code> then prints <code>--More--</code> and <code>/usr/xpg4/bin/more</code> then prints <i>file</i> at the bottom of the screen. If more is reading from a file rather than a pipe, the percentage of characters displayed so far is also shown.</p> <p>The more utility scrolls up to display one more line in response to a RETURN character. more displays another screenful in response to a SPACE character. Other commands are listed below.</p> <p>The page utility clears the screen before displaying the next screenful of text. page only provides a one-line overlap between screens.</p> <p>The more utility sets the terminal to NOECHO mode, so that the output can be continuous. Commands that you type do not normally show up on your terminal, except for the / and ! commands.</p> <p>The <code>/usr/bin/more</code> utility exits after displaying the last specified file. <code>/usr/xpg4/bin/more</code> prompts for a command at the last line of the last specified file.</p> <p>If the standard output is not a terminal, more acts just like <code>cat(1)</code>, except that a header is printed before each file in a series.</p> |
| <b>OPTIONS</b>                    | <p>The following options are supported for both <code>/usr/bin/more</code> and <code>/usr/xpg4/bin/more</code>:</p> <ul style="list-style-type: none"> <li>-c        Clears before displaying. Redraws the screen instead of scrolling for faster displays. This option is ignored if the terminal does not have the ability to clear to the end of a line.</li> <li>-d        Displays error messages rather than ringing the terminal bell if an unrecognized command is used. This is helpful for inexperienced users.</li> <li>-s        Squeeze. Replaces multiple blank lines with a single blank line. This is helpful when viewing <code>nroff(1)</code> output on the screen.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b><code>/usr/bin/more</code></b> | The following options are supported for <code>/usr/bin/more</code> only:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## more(1)

|                   |                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f                | Does not fold long lines. This is useful when lines contain nonprinting characters or escape sequences, such as those generated when <code>nroff(1)</code> output is piped through <code>ul(1)</code> .                                                                                                                                                    |
| -l                | Does not treat FORMFEED characters (Control-l) as page breaks. If <code>-l</code> is not used, <code>more</code> pauses to accept commands after any line containing a <code>^L</code> character (Control-l). Also, if a file begins with a FORMFEED, the screen is cleared before the file is printed.                                                    |
| -r                | Normally, <code>more</code> ignores control characters that it does not interpret in some way. The <code>-r</code> option causes these to be displayed as <code>^C</code> where <code>C</code> stands for any such control character.                                                                                                                      |
| -u                | Suppresses generation of underlining escape sequences. Normally, <code>more</code> handles underlining, such as that produced by <code>nroff(1)</code> , in a manner appropriate to the terminal. If the terminal can perform underlining or has a stand-out mode, <code>more</code> supplies appropriate escape sequences as called for in the text file. |
| -w                | Normally, <code>more</code> exits when it comes to the end of its input. With <code>-w</code> , however, <code>more</code> prompts and waits for any key to be struck before exiting.                                                                                                                                                                      |
| -lines            | Displays the indicated number of <i>lines</i> in each screenful, rather than the default (the number of lines in the terminal screen less two).                                                                                                                                                                                                            |
| +linenumber       | Start up at <i>linenumber</i> .                                                                                                                                                                                                                                                                                                                            |
| +/ <i>pattern</i> | Start up two lines above the line containing the regular expression <i>pattern</i> . <i>Note</i> : Unlike editors, this construct should <i>not</i> end with a <code>'/'</code> . If it does, then the trailing slash is taken as a character in the search pattern.                                                                                       |

### **/usr/xpg4/bin/more**

The following options are supported for `/usr/xpg4/bin/more` only:

|                                       |                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -e                                    | Exits immediately after writing the last line of the last file in the argument list.                                                                                                                                                                                                                                                                               |
| -i                                    | Performs pattern matching in searches without regard to case.                                                                                                                                                                                                                                                                                                      |
| -n <i>number</i>                      | Specifies the number of lines per screenful. The <i>number</i> argument is a positive decimal integer. The <code>-n</code> option overrides any values obtained from the environment.                                                                                                                                                                              |
| -p <i>command</i><br>+ <i>command</i> | For each file examined, initially executes the <code>more</code> command in the <i>command</i> argument. If the command is a positioning command, such as a line number or a regular expression search, set the current position to represent the final results of the command, without writing any intermediate lines of the file. For example, the two commands: |

```
more -p 1000j file
more -p 1000G file
```

are equivalent and start the display with the current position at line 1000, bypassing the lines that `j` would write and scroll off the screen if it had been issued during the file examination. If the positioning command is unsuccessful, the first line in the file will be the current position.

- t *tagstring*      Writes the screenful of the file containing the tag named by the *tagstring* argument. See the `ctags(1)` utility.
- u                    Treats a backspace character as a printable control character, displayed as a `^H` (Control-h), suppressing backspacing and the special handling that produces underlined or standout-mode text on some terminal types. Also, does not ignore a carriage-return character at the end of a line.

If both the `-t tagstring` and `-p command` (or the obsolescent `+command`) options are given, the `-t tagstring` is processed first.

**Environment**      `more` uses the terminal's `terminfo(4)` entry to determine its display characteristics.

`more` looks in the environment variable `MORE` for any preset options. For instance, to page through files using the `-c` mode by default, set the value of this variable to `-c`. (Normally, the command sequence to set up this environment variable is placed in the `.login` or `.profile` file).

**Commands**        The commands take effect immediately. It is not necessary to type a carriage return unless the command requires a *file*, *command*, *tagstring*, or *pattern*. Up to the time when the command character itself is given, the user may type the line kill character to cancel the numerical argument being formed. In addition, the user may type the erase character to redisplay the `'--More-- (xx%)'` or *file* message.

In the following commands, *i* is a numerical argument (1 by default).

- i*SPACE            Display another screenful, or *i* more lines if *i* is specified.
- i*RETURN           Display another line, or *i* more lines, if specified.
- i*b  
*i*^B                (Control-b) Skip back *i* screenfuls and then print a screenful.
- i*d  
*i*^D                (Control-d) Scroll forward one half screenful or *i* more lines. If *i* is specified, the count becomes the default for subsequent `d` and `u` commands.
- i*f                   Skip *i* screens full and then print a screenful.
- h                    Help. Give a description of all the `more` commands.
- ^L                   (Control-l) Refresh.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>i</i> n                | Search for the <i>i</i> th occurrence of the last <i>pattern</i> entered.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| q                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Q                         | Exit from more.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>is</i>                 | Skip <i>i</i> lines and then print a screenful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| v                         | Drop into the vi editor at the current line of the current file.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>iz</i>                 | Same as SPACE, except that <i>i</i> , if present, becomes the new default number of lines per screenful.                                                                                                                                                                                                                                                                                                                                                                                                         |
| =                         | Display the current line number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>i/pattern</i>          | Search forward for the <i>i</i> th occurrence of the regular expression <i>pattern</i> . Display the screenful starting two lines before the line that contains the <i>i</i> th match for the regular expression <i>pattern</i> , or the end of a pipe, whichever comes first. If more is displaying a file and there is no match, its position in the file remains unchanged. Regular expressions can be edited using erase and kill characters. Erasing back past the first column cancels the search command. |
| ! <i>command</i>          | Invoke a shell to execute <i>command</i> . The characters % and !, when used within <i>command</i> are replaced with the current filename and the previous shell command, respectively. If there is no current filename, % is not expanded. Prepend a backslash to these characters to escape expansion.                                                                                                                                                                                                         |
| :f                        | Display the current filename and line number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>i</i> :n               | Skip to the <i>i</i> th next filename given in the command line, or to the last filename in the list if <i>i</i> is out of range.                                                                                                                                                                                                                                                                                                                                                                                |
| <i>i</i> :p               | Skip to the <i>i</i> th previous filename given in the command line, or to the first filename if <i>i</i> is out of range. If given while more is positioned within a file, go to the beginning of the file. If more is reading from a pipe, more simply rings the terminal bell.                                                                                                                                                                                                                                |
| :q                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| :Q                        | Exit from more (same as q or Q).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>/usr/bin/more</b>      | The following commands are available only in /usr/bin/more:                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| '                         | Single quote. Go to the point from which the last search started. If no search has been performed in the current file, go to the beginning of the file.                                                                                                                                                                                                                                                                                                                                                          |
| .                         | Dot. Repeat the previous command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ^ \                       | Halt a partial display of text. more stops sending output, and displays the usual --More-- prompt. Some output is lost as a result.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>/usr/xpg4/bin/more</b> | The following commands are available only in /usr/xpg4/bin/more:                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>i</i> ^F               | (Control-f) Skip <i>i</i> screens full and print a screenful. (Same as <i>if</i> .)                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                           |                                                                                                                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>^G</code>           | (Control-g) Display the current line number (same as =).                                                                                                                                               |
| <code>ig</code>           | Go to line number <i>i</i> with the default of the first line in the file.                                                                                                                             |
| <code>iG</code>           | Go to line number <i>i</i> with the default of the Last line in the file.                                                                                                                              |
| <code>ij</code>           | Display another line, or <i>i</i> more lines, if specified. (Same as <i>i</i> RETURN.)                                                                                                                 |
| <code>ik</code>           | Scroll backwards one or <i>i</i> lines, if specified.                                                                                                                                                  |
| <code>mletter</code>      | Mark the current position with the name <i>letter</i> .                                                                                                                                                |
| <code>N</code>            | Reverse direction of search.                                                                                                                                                                           |
| <code>r</code>            | Refresh the screen.                                                                                                                                                                                    |
| <code>R</code>            | Refresh the screen, discarding any buffered input.                                                                                                                                                     |
| <code>iü</code>           |                                                                                                                                                                                                        |
| <code>i^U</code>          | (Control-u) Scroll backwards one half a screen of <i>i</i> lines, if specified. If <i>i</i> is specified, the count becomes the new default for subsequent <code>d</code> and <code>u</code> commands. |
| <code>ZZ</code>           | Exit from <code>more</code> (same as <code>q</code> ).                                                                                                                                                 |
| <code>:e file</code>      | Examine (display) a new file. If no <i>file</i> is specified, the current file is redisplayed.                                                                                                         |
| <code>:t tagstring</code> | Go to the tag named by the <i>tagstring</i> argument and scroll/rewrite the screen with the tagged line in the current position. See the <code>ctags</code> utility.                                   |
| <code>' letter</code>     | Return to the position that was previously marked with the name <i>letter</i> .                                                                                                                        |
| <code>''</code>           | Return to the position from which the last move of more than a screenful was made. Defaults to the beginning of the file.                                                                              |
| <code>i?[!]pattern</code> | Search backward in the file for the <i>ith</i> line containing the <i>pattern</i> . The <code>!</code> specifies to search backward for the <i>ith</i> line that does not contain the <i>pattern</i> . |
| <code>i/!pattern</code>   | Search forward in the file for the <i>ith</i> line that does not contain the <i>pattern</i> .                                                                                                          |
| <code>![command]</code>   | Invoke a shell or the specified command.                                                                                                                                                               |

### Large File Behavior

See `largefile(5)` for the description of the behavior of `more` and `page` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `more`: `LANG`, `LC_ALL`, `LC_COLLATE` (`/usr/xpg4/bin/more` only), `LC_CTYPE`, `LC_MESSAGES`, `NLSPATH`, and `TERM`.

more(1)

**/usr/xpg4/bin/more**

The following environment variables also affect the execution of /usr/xpg4/bin/more:

**COLUMNS** Overrides the system selected horizontal screen size.

**EDITOR** Used by the v command to select an editor.

**LINES** Overrides the system selected vertical screen size. The -n option has precedence over LINES in determining the number of lines in a screen.

**MORE** A string specifying options as described in the OPTIONS section, above. As in a command line, The options must be separated by blank characters and each option specification must start with a -. Any command line options are processed after those specified in MORE as though the command line were: more \$MORE *options operands*

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**FILES**

/usr/lib/more.help help file for /usr/bin/more and /usr/bin/page only.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

**/usr/bin/more**  
**/usr/bin/page**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Not enabled     |

**/usr/xpg4/bin/more**

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| CSI                 | Enabled         |
| Interface Stability | Standard        |

| <b>DESCRIPTION</b> | <p>The mp program, when called without the -D or -P option, reads each <i>filename</i> in sequence and generates a prettified version of the contents in PostScript™ format, sent to standard output. If no filename argument is provided, mp reads the standard input. If the standard input is a terminal, input is terminated by an EOF signal, usually Control-d.</p> <p>The -D and -P options require the target printer name as an argument and produce the Page Description Language (PDL) of the target printer. The -D option causes the PDL to output to stdout and the -P option causes the PDL to be directly spooled to the printer. In the absence of these options, mp will product default PostScript™ output.</p> <p>The mp program accepts international text files of various Solaris locales and produces output which is proper for the specified locale. The output will also contain proper text layout. For instance, the output will contain bidirectional text rendering, and also shaping, since the complex text layout (CTL) is supported in mp.</p> <p>Mail items, news articles, ordinary ASCII files, complete mail folders, and digests are all acceptable input formats for mp. The output format includes grayscale lozenges, or the outline of the same dimensions as the lozenges, containing banner information at the top and bottom of every page.</p> |    |                                                                                                                                                                                         |     |                                           |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                                    |    |                               |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <table><tr><td>-a</td><td>Formats the file as a news article. The top banner contains the text: "Article from <i>newsgroup</i>", where <i>newsgroup</i> is the first news group found on the "Newsgroups:" line.</td></tr><tr><td>-A4</td><td>Uses A4 paper size (8.26 x 11.69 inches).</td></tr><tr><td>-c <i>chars</i></td><td>The maximum number of characters to extract from the <i>gecos</i> field of the user's <i>/etc/passwd</i> entry. The default is 18.</td></tr><tr><td>-C</td><td>Instead of using "\nFrom" to denote the start of new mail messages, mp will look for (and use) the value of the Content-Length: mail header. If the Content-Length doesn't take you to the next "\nFrom", then it is wrong, and mp falls back to looking for the next "\nFrom" in the mail folder.</td></tr><tr><td>-d</td><td>Formats the file as a digest.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | -a | Formats the file as a news article. The top banner contains the text: "Article from <i>newsgroup</i> ", where <i>newsgroup</i> is the first news group found on the "Newsgroups:" line. | -A4 | Uses A4 paper size (8.26 x 11.69 inches). | -c <i>chars</i> | The maximum number of characters to extract from the <i>gecos</i> field of the user's <i>/etc/passwd</i> entry. The default is 18. | -C | Instead of using "\nFrom" to denote the start of new mail messages, mp will look for (and use) the value of the Content-Length: mail header. If the Content-Length doesn't take you to the next "\nFrom", then it is wrong, and mp falls back to looking for the next "\nFrom" in the mail folder. | -d | Formats the file as a digest. |
| -a                 | Formats the file as a news article. The top banner contains the text: "Article from <i>newsgroup</i> ", where <i>newsgroup</i> is the first news group found on the "Newsgroups:" line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                                                                                                                                                                                         |     |                                           |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                                    |    |                               |
| -A4                | Uses A4 paper size (8.26 x 11.69 inches).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                                                                                                                                                                                         |     |                                           |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                                    |    |                               |
| -c <i>chars</i>    | The maximum number of characters to extract from the <i>gecos</i> field of the user's <i>/etc/passwd</i> entry. The default is 18.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |    |                                                                                                                                                                                         |     |                                           |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                                    |    |                               |
| -C                 | Instead of using "\nFrom" to denote the start of new mail messages, mp will look for (and use) the value of the Content-Length: mail header. If the Content-Length doesn't take you to the next "\nFrom", then it is wrong, and mp falls back to looking for the next "\nFrom" in the mail folder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |    |                                                                                                                                                                                         |     |                                           |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                                    |    |                               |
| -d                 | Formats the file as a digest.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |    |                                                                                                                                                                                         |     |                                           |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                                    |    |                               |

|                                     |                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-D target_printer_name</code> | Produces the PDL for the target printer. Requires X Print Server connection.                                                                                                                                                                                                                                                                                                      |
| <code>-e</code>                     | Assumes the ELM mail frontend intermediate file format. Used when printing messages from within ELM (using the "p" command), especially for printing tagged messages. This option must be specified in your ELM option setup.                                                                                                                                                     |
| <code>-ff</code>                    | Formats the file for use with a Filofax personal organizer.                                                                                                                                                                                                                                                                                                                       |
| <code>-fp</code>                    | Formats the file for use with a Franklin Planner personal organizer.                                                                                                                                                                                                                                                                                                              |
| <code>-F</code>                     | Instead of printing who the mail article is <i>for</i> , the top header will contain who the mail article is <i>from</i> . A useful option for people with their own personal printer.                                                                                                                                                                                            |
| <code>-l</code>                     | Formats output in landscape mode. Two pages of text will be printed per sheet of paper.                                                                                                                                                                                                                                                                                           |
| <code>-ll</code>                    | Formats output in landscape mode. One page of text will be printed per sheet of paper. This is useful for printing files with longer than normal lines.                                                                                                                                                                                                                           |
| <code>-L localename</code>          | Provides the locale of the file to be printed. If this command line option is not present, then mp looks for the MP_LANG environment variable. If that is not present, then the LANG environment variable is used. If none of these options are present, then mp tries to determine the locale it is running in, and if it cannot, then it assumes it is running in the C locale. |
| <code>-m</code>                     | Formats the file as a mail folder, printing multiple messages.                                                                                                                                                                                                                                                                                                                    |
| <code>-M</code>                     | Forces mp to use the mp.conf file for printing output even if a prolog.ps file exists for that locale. Useful when printing to non-native PostScript™ printers.                                                                                                                                                                                                                   |
| <code>-n</code>                     | Turns off the gray bars and associated information from header and footer. Used to get output similar to output of 'lp filename'.                                                                                                                                                                                                                                                 |
| <code>-o</code>                     | Formats the file as an ordinary ASCII file.                                                                                                                                                                                                                                                                                                                                       |
| <code>-p prologue</code>            | Employs the file <i>prologue</i> as the PostScript/Xprt prologue file, overriding any previously defined file names. This file specifies the format of the print output. For PostScript output, the <i>prologue</i> file will have a .ps extension. For Xprt clients (when the -D option is                                                                                       |

## mp(1)

|                                |                                                                                                                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | specified), this file will have an .xpr extension. These files are defined in the SUPPLIED PROLOGUE FILES section below.                                                                                     |
| -P <i>target_spool_printer</i> | Spools the PDL to the target printer. No output is sent to stdout. Requires X Print Server connection.                                                                                                       |
| -PS                            | If the mail or digest message just has PostScript as the text of the message, this is normally just passed straight through. Specifying this option causes PostScript to be printed as text.                 |
| -s <i>subject</i>              | Uses <i>subject</i> as the new subject for the printout. If you are printing ordinary ASCII files that have been specified on the command line, the subject will default to the name of each of these files. |
| -tm                            | Formats the file for use with the Time Manager personal organizer.                                                                                                                                           |
| -ts                            | Formats the file for use with the Time/System International personal organizer.                                                                                                                              |
| -US                            | Uses US paper size (8.5 x 11 inches). This is the default paper size.                                                                                                                                        |
| -u <i>config_file_path</i>     | Specifies an alternate configuration file to the default file<br><i>/usr/lib/lp/locale/locale_name/mp/mp.conf</i> .<br>The absolute file path name must be used.                                             |
| -v                             | Prints the version number of this release of mp.                                                                                                                                                             |
| -w <i>words</i>                | The maximum number of words to extract from the <i>gecos</i> field of the user's <i>/etc/passwd</i> entry. The default is 3.                                                                                 |
| -z <i>point_size</i>           | Prints the output text in the point size specified by <i>point_size</i> . The internal default is 12 points for portrait printing and 9 points for landscape printing.                                       |
| -?                             | Prints the usage line for mp (notice that the ? character must be escaped if using <i>csh(1)</i> ).                                                                                                          |

**OPERANDS** The following operand is supported:

*filename*            The name of the file to be read.

**EXAMPLES** The mp print filter can be used to print files in any locale which is installed in the user's machine.

**EXAMPLE 1** Printing Japanese text files

Japanese text files encoded in the `euC` codeset can be printed in any non-Japanese PostScript™ printers by entering:

```
example% mp -L ja_JP.eucJP -M ja_JP_eucJP.txt | lp
```

Here, the `-L` option specifies the locale and the `-M` option invokes the `mp.conf` configuration file instead of the default `prolog.ps` file. In the case of `ja_JP.eucJP`, both `/usr/lib/lp/locale/ja_JP.eucJP/mp/mp.conf` and `/usr/openwin/lib/locale/ja_JP.eucJP/print/prolog.ps` files are present. Therefore, the `-M` option is used to override the precedence of the default `prolog.ps` file. Using `mp.conf` as the configuration file makes it possible to print to any PostScript printer.

The encoding of the locale specified by the `-L` option and that of the text file to be printed have to be the same. In the above Japanese file example, if the text file is encoded in `Shift-JIS`, use the following command, since the locale `ja_JP.PCK` is encoded in `SJIS`:

```
example% mp -L ja_JP.PCK -M SJIS.txt | lp
```

**EXAMPLE 2** Running in `Xprt` mode

If an X Print Server daemon (`/usr/openwin/bin/Xprt`) is running in any system in the network, then `mp` can be invoked as follows, enabling it to output in any Page Description Language supported by `Xprt` (the default value of `display_number` is 2100):

```
example% setenv XPDISPLAY machine_name:display_number
```

To pipe the data to the target printer, enter:

```
example% mp -D printer_name -L ja_JP.eucJP -M ja_JP_eucJP.txt | lp
-D printer_name
```

For direct spooling when working in `Xprt` client mode, use the `-P` option:

```
example% mp -P printer_name -L ja_JP.eucJP -M ja_JP_eucJP.txt
```

**EXAMPLE 3** Turning off the header and footer

Use the `-n` option to turn off the `mp` header and footer:

```
example% mp -n mytext.txt | lp
```

**EXAMPLE 4** Printing long text lines

Use the `-ll` option to print text files with longer than 80 column lines in landscape mode:

mp(1)

**EXAMPLE 4** Printing long text lines (Continued)

```
example% mp -ll mytext.txt | lp
```

**EXAMPLE 5** Specifying print point size

Use the `-z` option to specify any point size, in this case, 20 points:

```
example% mp -z 20 mytext.txt | lp
```

## ENVIRONMENT VARIABLES

**XPDISPLAY** If either the `-D` or `-P` option is specified in the command line and there is no `XPDISPLAY` variable set in the environment, the print server startup script will start an `Xprt` server at port 2100 in the machine in which the client is running. The script will terminate the print server once the job is over. If `XPDISPLAY` is set, the `mp` client will try to contact the print server running at `XPDISPLAY`. In this case, no attempt will be made to start the server if it is not running.

**MP\_PROLOGUE** Used to determine the directory where the page formatting files (`.xpr` or `.ps`) are kept. These files determine page decorations, number of logical pages per physical page, landscape or portrait format, and so forth. In the absence of `MP_PROLOGUE`, the default location of the directory is `/usr/lib/lp/locale/C/mp`.

**MP\_LANG**  
**LANG** If neither of the `-D` or `-P` options is specified, a prologue file is prepended to the output to be printed. The prologue file is called `/usr/openwin/lib/locale/localename/print/prolog.ps` or `/usr/lib/lp/locale/localename/mp/prolog.ps`, where *localename* is the value of the `MP_LANG` or `LANG` environment variable, if present. If both variables are present, the file `/usr/openwin/lib/locale/localename/print/prolog.ps` is given preference due to backward compatibility reasons. If either of these files are not present, and the `-D` option is not specified, a configuration file of the locale called `/usr/lib/lp/locale/localename/mp/mp.conf` is used as the source of the configuration information that substitutes the prologue information for printing. The presence of `prolog.ps` disables `mp.conf` for backward compatibility.

**EXIT STATUS** The following exit values are returned:

|   |                        |
|---|------------------------|
| 0 | Successful completion. |
| 1 | An error occurred.     |

**SUPPLIED  
PROLOGUE  
FILES**

The following prologue files are provided. Files with `.ps` extensions are for the PostScript output. Files with `.xpr` extensions are for the Print Server client. `.xpr` files are created for 300dpi printers and will scale to other resolution values.

|                                                             |                                                                                                                                  |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>mp.common.ps</code>                                   | Common prologue file for all other <code>.ps</code> files in this directory.                                                     |
| <code>mp.pro.ps</code><br><code>mp.pro.xpr</code>           | Used by default.                                                                                                                 |
| <code>mp.pro.ff.ps</code><br><code>mp.pro.ff.xpr</code>     | Used if the <code>-ff</code> option is in effect.                                                                                |
| <code>mp.pro.fp.ps</code><br><code>mp.pro.fp.xpr</code>     | Used if the <code>-fp</code> option is in effect.                                                                                |
| <code>mp.pro.tm.ps</code><br><code>mp.pro.tm.xpr</code>     | Used if the <code>-tm</code> option is in effect.                                                                                |
| <code>mp.pro.ts.ps</code><br><code>mp.pro.ts.xpr</code>     | Used if the <code>-ts</code> option is in effect.                                                                                |
| <code>mp.pro.alt.ps</code><br><code>mp.pro.alt.xpr</code>   | An alternative modification of the default prologue file which outputs the page number in the right corner of the bottom banner. |
| <code>mp.pro.l.ps</code><br><code>mp.pro.l.xpr</code>       | Prologue file used for landscape outputs.                                                                                        |
| <code>mp.pro.ll.ps</code><br><code>mp.pro.ll.xpr</code>     | Prologue file used for landscape outputs, when printing files with longer than normal lines.                                     |
| <code>mp.pro.altl.ps</code><br><code>mp.pro.altl.xpr</code> | Alternate prologue file used for landscape outputs.                                                                              |

**FILES**

|                                                                                                   |                                                                                                               |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>.cshrc</code>                                                                               | Initialization file for <code>cs(1)</code> .                                                                  |
| <code>.mailrc</code>                                                                              | Initialization file for <code>mail(1)</code> .                                                                |
| <code>/usr/bin/mp</code>                                                                          | Executable.                                                                                                   |
| <code>/usr/lib/lp/locale/C/mp/mp.conf</code>                                                      | Default configuration file.                                                                                   |
| <code>/usr/lib/lp/locale/C/mp/mp.common.ps</code>                                                 | Common prologue file for all other <code>.ps</code> files in this directory. Not for <code>.xpr</code> files. |
| <code>/usr/lib/lp/locale/C/mp/mp.pro.ps</code><br><code>/usr/lib/lp/locale/C/mp/mp.pro.xpr</code> | Default prologue files for mail printing.                                                                     |

## mp(1)

`/usr/lib/lp/locale/C/mp/mp.pro.l.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.l.xpr`  
Default prologue files for landscape format.

`/usr/lib/lp/locale/C/mp/mp.pro.ll.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.ll.xpr`  
Default prologue files for landscape format with one column per page. Useful when printing files with long lines.

`/usr/lib/lp/locale/C/mp/mp.pro.altl.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.altl.xpr`  
Alternate prologue files for landscape format.

`/usr/lib/lp/locale/C/mp/mp.pro.alt.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.alt.xpr`  
Alternative "default" prologue files. Insert page numbers in the bottom right corner of each page.

`/usr/lib/lp/locale/C/mp/mp.pro.ff.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.ff.xpr`  
Default prologue files for Filofax format.

`/usr/lib/lp/locale/C/mp/mp.pro.fp.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.fp.xpr`  
Default prologue files for Franklin Planner format.

`/usr/lib/lp/locale/C/mp/mp.pro.tm.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.tm.xpr`  
Default prologue files for Time Manager format.

`/usr/lib/lp/locale/C/mp/mp.pro.ts.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.ts.xpr`  
Default prologue files for Time/System International format.

`/usr/openwin/lib/locale/localename/print/prolog.ps`  
`/usr/lib/lp/locale/localename/mp/prolog.ps`  
Default locale-specific prologued file as an alternative to the `mp.conf` file. See ENVIRONMENT VARIABLES for more detail on the relationship.

The structure and format for `mp.conf` and `.xpr` files are documented in the *International Language Environments Guide*. Refer to this document if you need to use alternate fonts, including Printer Resident Fonts, or if you want to make changes to output format.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmp          |

| <b>NAME</b>                  | mpss.so.1 – shared object for setting preferred page size                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>              | <b>mpss.so.1</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b>           | <p>The <code>mpss.so.1</code> shared object provides a means by which the preferred stack and/or heap page size can be selectively configured for launched processes and their descendants. To enable <code>mpss.so.1</code>, the following string needs to be present in the environment (see <code>ld.so.1(1)</code>) along with one or more MPSS (Multiple Page Size Support) environment variables:</p> <pre>LD_PRELOAD=\$LD_PRELOAD:mpss.so.1</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ENVIRONMENT VARIABLES</b> | <p>Once preloaded, the <code>mpss.so.1</code> shared object reads the following environment variables to determine any preferred page size requirements and any processes these may be specific to.</p> <p><code>MPSSHEAP=size</code><br/><code>MPSSSTACK=size</code></p> <p><code>MPSSHEAP</code> and <code>MPSSSTACK</code> specify the preferred page sizes for the heap and stack, respectively. The specified page size(s) are applied to all created processes.</p> <p><i>size</i> must be a supported page size (see <code>pagesize(1)</code>) or 0, in which case the system will select an appropriate page size (see <code>memcntl(2)</code>).</p> <p><i>size</i> can be qualified with K, M, G, or T to specify Kilobytes, Megabytes, Gigabytes, or Terabytes respectively.</p> <p><code>MPSSCFGFILE=config-file</code></p> <p><i>config-file</i> is a text file which contains one or more <code>mpss</code> configuration entries of the form:</p> <pre>exec-name exec-args : heap-size : stack-size</pre> <p><i>exec-name</i> specifies the name of an application or executable. The corresponding preferred page size(s) are set for newly created processes (see <code>getexecname(3C)</code>) that match the first <i>exec-name</i> found in the file.</p> <p><i>exec-name</i> can be a full pathname, a base name or a pattern string. See <code>File Name Generation</code> in <code>sh(1)</code> for a discussion of pattern matching.</p> <p><i>exec-args</i> is an optionally specified pattern string to match against arguments. Preferred page size(s) are set only if <i>exec-args</i> is not specified or occurs within the arguments to <i>exec-name</i>.</p> <p>If <i>heap-size</i> and/or <i>stack-size</i> are not specified, the corresponding preferred page size(s) will not be set.</p> |

MPSSCFGFILE takes precedence over MPSSHEAP and MPSSSTACK. When MPSSCFGFILE is not set, preferred page size settings are taken from file `/etc/mpss.conf` if it exists.

MPSSERRFILE=*pathname*

By default, error messages are logged via `syslog(3C)` using level `LOG_ERR` and facility `LOG_USER`. If `MPSSERRFILE` contains a valid *pathname* (such as `/dev/stderr`), error messages will be logged there instead.

## EXAMPLES

### EXAMPLE 1 Configuring preferred page sizes using MPSSCFGFILE

The following Bourne shell commands (see `sh(1)`) configure the preferred page sizes to a select set of applications with exec names that begin with `foo`, using the `MPSSCFGFILE` environment variable. The MPSS configuration file, `mpsscfcfg`, is assumed to have been previously created via a text editor like `vi(1)`. The `cat(1)` command is only dumping out the contents.

```
example$ LD_PRELOAD=$LD_PRELOAD:mpss.so.1
example$ MPSSCFGFILE=mpsscfcfg
example$ export LD_PRELOAD MPSSCFGFILE
example$ cat $MPSSCFGFILE
foo*:512K:64K
```

Once the application has been started, `pmap` (see `proc(1)`) can be used to view the actual page sizes configured:

```
example$ foobar &
example$ pmap -s `pgrep foobar`
```

If the desired page size is not configured (shown in the `pmap` output), it may be due to errors in the MPSS configuration file or environment variables. Check the error log (by default: `/var/adm/messages`) for errors.

If no errors can be found, resource or alignment constraints may be responsible. See the NOTES section.

### EXAMPLE 2 Configuring preferred page sizes using MPSSHEAP and MPSSSTACK

The following Bourne shell commands configure 512K heap and 64K stack preferred page sizes for all applications using the `MPSSHEAP` and `MPSSSTACK` environment variables.

```
example$ LD_PRELOAD=$LD_PRELOAD:mpss.so.1
example$ MPSSHEAP=512K
example$ MPSSSTACK=64K
example$ export LD_PRELOAD MPSSHEAP MPSSSTACK
```

mpss.so.1(1)

**EXAMPLE 3** Precedence rules (continuation from Example 2)

The preferred page size configuration in `MPSSCFGFILE` overrides `MPS SHEAP` and `MPS STACK`. Appending the following commands to those in Example 2 would mean that all applications will be configured with 512K heap and 64K stack preferred page sizes with the exception of those applications, the `ls` command, and all applications beginning with `ora` that have `ora1` as an argument, in the configuration file.

```
example$ MPSSCFGFILE=mpsscfig2
example$ export MPSSCFGFILE
example$ cat $MPSSCFGFILE
ls::
ora* ora1:4m:4m
```

**FILES** `/usr/lib/ld/map.bssalign` A template link-editor `mapfile` for aligning bss (see NOTES).  
`/etc/mpss.conf` Configuration file

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE   |
|---------------------|-------------------|
| Availability        | SUNWesu (32-bit)  |
|                     | SUNWesxu (64-bit) |
| Interface Stability | Evolving          |

**SEE ALSO** `cat(1)`, `ld(1)`, `ld.so.1(1)`, `pagesize(1)`, `ppgsz(1)`, `proc(1)`, `sh(1)`, `vi(1)`, `exec(2)`, `fork(2)`, `memcntl(2)`, `getexecname(3C)`, `getpagesize(3C)`, `syslog(3C)`, `proc(4)`, `attributes(5)`

**NOTES** The heap and stack preferred page sizes are inherited. A child process has the same preferred page sizes as its parent. On `exec(2)`, the preferred page sizes are set back to the default system page size unless a preferred page size has been configured via the `mpss` shared object.

`ppgsz(1)`, a `proc` tool, can also be used to set the preferred stack and/or heap page sizes. It cannot selectively configure the page size for descendents based on name matches.

See also NOTES under `ppgsz(1)`.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | msgfmt – create a message object from a message file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <b>msgfmt</b> [-D <i>dir</i>   --directory= <i>dir</i> ] [-f   --use-fuzzy] [-g]<br>[-o <i>output-file</i>   --output-file= <i>output-file</i> ] [-s] [--strict] [-v]<br>[--verbose] <i>filename</i> .po...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>The msgfmt utility creates message object files from portable object files (<i>filename</i>.po), without changing the portable object files.</p> <p>The .po file contains messages displayed to users by system commands or by application programs. .po files can be edited. The messages in these files can be rewritten in any language supported by the system.</p> <p>The xgettext(1) command can be used to create .po files from script or programs.</p> <p>msgfmt interprets data as characters according to the current setting of the LC_CTYPE locale category or according to the codeset specified in the .po file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-D <i>dir</i><br/>         --directory=<i>dir</i>                    Adds <i>dir</i> to the list for input files search.</p> <p>-f<br/>         --use-fuzzy                         Uses fuzzy entries in output. If this option is not specified, fuzzy entries are not included into the output. These options are ignored if Solaris message catalogs are processed.</p> <p>-g                                       Directs the utility to generate the GNU-compatible message catalog file. This option cannot be specified with the -s option.</p> <p>-o <i>output-file</i><br/>         --output=<i>output-file</i>               Specifies the output file name as <i>output-file</i>. All domain directives and duplicate msgids in the .po file are ignored.</p> <p>-s                                       Directs the utility to generate the Solaris message catalog file. This option cannot be specified with the -g option.</p> <p>--strict                               Directs the utility to append the suffix .mo to the generating message object file name if it doesn't have this suffix. This option is ignored if Solaris message catalogs are processed.</p> <p>-v<br/>         --verbose                             Verbose. Lists duplicate message identifiers if Solaris message catalog files are processed. Message strings are not redefined.</p> |

If GNU-compatible message files are processed, this option detects and diagnoses input file anomalies which might represent translation errors. The `msgid` and `msgstr` strings are studied and compared. It is considered abnormal if one string starts or ends with a newline while the other does not. Also, if the string represents a format string used in a `printf`-like function, both strings should have the same number of `%` format specifiers, with matching types. If the flag `c-format` appears in the special comment `'#'` for this entry, a check is performed.

**USAGE** The format of portable object files (`.po` files) is defined as follows. Each `.po` file contains one or more lines, with each line containing either a comment or a statement. Comments start the line with a pound sign (`#`) and end with the newline character. All comments (except special comments described later) and empty lines are ignored. The format of a statement is:

*directive value*

Each *directive* starts at the beginning of the line and is separated from *value* by white space (such as one or more space or tab characters). *value* consists of one or more quoted strings separated by white space. Use any of the following types of directives for the Solaris message file:

`domain domainname`  
`msgid message_identifier`  
`msgstr message_string`

For a GNU-compatible message file, use any of the following types of directives:

`domain domainname`  
`msgid message_identifier`  
`msgid_plural untranslated_string_plural`  
`msgstr message_string`  
`msgstr[n] message_string`

The behavior of the `domain` directive is affected by the options used. See **OPTIONS** for the behavior when the `-o` or `--output-file` options are specified. If the `-o` or `--output-file` options are not specified, the behavior of the `domain` directive is as follows:

- All `msgids` from the beginning of each `.po` file to the first `domain` directive are put into a default message object file. The default message object file is named `messages.mo`, if the Solaris message catalog file format is used to generate the message object file or if the `--strict` option is specified. Otherwise, the default message object file is named `messages`.

- When msgfmt encounters a domain *domainname* directive in the .po file, all following msgids until the next domain directive are put into the message object file, named *domainname.mo*, if the Solaris message catalog file format is used to generate the message object file or if the `--strict` option is specified. Otherwise, the msgids are put into the message object file named *domainname*.
- Duplicate msgids are defined in the scope of each domain. That is, a msgid is considered a duplicate only if the identical msgid exists in the same domain.
- All duplicate msgids are ignored.

The `msgid` directive specifies the value of a message identifier associated with the directive that follows it. The `msgid_plural` directive specifies the plural form message specified to the plural message handling functions `ngettext()`, `dngettext()`, or `dcngettext()`. The *message\_identifier* string identifies a target string to be used at retrieval time. Each statement containing a `msgid` directive must be followed by a statement containing a `msgstr` directive or `msgstr[n]` directives.

The `msgstr` directive specifies the target string associated with the *message\_identifier* string declared in the immediately preceding `msgid` directive.

The directive `msgstr[n]` (where  $n = 0, 1, 2, \dots$ ) specifies the target string to be used with plural form handling functions `ngettext()`, `dngettext()`, and `dcngettext()`.

Message strings can contain the escape sequences `\n` for newline, `\t` for tab, `\v` for vertical tab, `\b` for backspace, `\r` for carriage return, `\f` for formfeed, `\\` for backslash, `\"` for double quote, `\a` for alarm, `\ddd` for octal bit pattern, and `\xDD` for hexadecimal bit pattern.

Comments for a GNU-compatible message file should be in one of the following formats (the msgfmt utility will ignore these comments when processing Solaris message files):

```
translator-comments
. automatic-comments
: reference..
, flag
```

The `'#:'` comments indicate the location of the msgid string in the source files in *filename:line* format. The `'#'`, `'#.'`, and `'#:'` comments are informative only and are silently ignored by the msgfmt utility. The `'#,'` comments require one or more flags separated by the comma character. The following *flags* can be specified:

|       |                                                                                                                                                                                                                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fuzzy | This flag can be inserted by the translator. It shows that the <code>msgstr</code> string might not be a correct translation (anymore). Only the translator can judge if the translation requires further modification or is acceptable as is. Once satisfied with the translation, the translator removes this fuzzy flag. If this flag is |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## msgfmt(1)

specified, the `msgfmt` utility will not generate the entry for the immediately following `msgid` in the output message catalog.

`c-format`

`no-c-format`

The `c-format` flag indicates that the `msgid` string is used as a format string by `printf`-like functions. In case the `c-format` flag is given for a string, the `msgfmt` utility does some more tests to check the validity of the translation.

In the GNU-compatible message file, the `msgid` entry with empty string ("" ) is called the header entry and treated specially. If the message string for the header entry contains `nplurals=value`, the value indicates the number of plural forms. For example, if `nplurals=4`, there are four plural forms. If `nplurals` is defined, the same line should contain `plural=expression`, separated by a semicolon character. The *expression* is a C language expression to determine which version of `msgstr[n]` is to be used based on the value of *n*, the last argument of `ngettext()`, `dngettext()`, or `dcngettext()`. For example,

```
nplurals=2; plural= n == 1 ? 0 : 1
```

indicates that there are two plural forms in the language. `msgstr[0]` is used if `n == 1`, otherwise `msgstr[1]` is used. For another example:

```
nplurals=3; plural= n == 1 ? 0 : n == 2 ? 1 : 2
```

indicates that there are three plural forms in the language. `msgstr[0]` is used if `n == 1`, `msgstr[1]` is used if `n == 2`, otherwise `msgstr[2]` is used.

If the header entry contains a `charset=codeset` string, the *codeset* is used to indicate the codeset to be used to encode the message strings. If the output string's codeset is different from the message string's codeset, codeset conversion from the message string's codeset to the output string's codeset will be performed upon the call of `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, and `dcngettext()` for the GNU-compatible message catalogs. The output string's codeset is determined by the current locale's codeset (the return value of `nl_langinfo(CODESET)`) by default, and can be changed by the call of `bind_textdomain_codeset()`.

### Message catalog file format

The `msgfmt` utility can generate the message object both in Solaris message catalog file format and in GNU-compatible message catalog file format. If the `-s` option is specified and the input file is a Solaris `.po` file, the `msgfmt` utility generates the message object in Solaris message catalog file format. If the `-g` option is specified and the input file is a GNU `.po` file, the `msgfmt` utility generates the message object in GNU-compatible message catalog file format. If neither the `-s` nor `-g` option is specified, the `msgfmt` utility determines the message catalog file format as follows:

- If the `.po` file contains a valid GNU header entry (having an empty string for `msgid`), the `msgfmt` utility uses the GNU-compatible message catalog file format.
- Otherwise, the `msgfmt` utility uses the Solaris message catalog file format.

If the `msgfmt` utility determined that the Solaris message catalog file format is used, as above, but found the `.po` file contains directives that are specific to the GNU-compatible message catalog file format, such as `msgid_plural` and `msgstr[n]`, the `msgfmt` utility handles those directives as invalid specifications.

**EXAMPLES****EXAMPLE 1** Creating message objects from message files

In this example, `module1.po` and `module2.po` are portable message objects files.

```
example% cat module1.po
default domain "messages.mo"
msgid "msg 1"
msgstr "msg 1 translation"
#
domain "help_domain"
msgid "help 2"
msgstr "help 2 translation"
#
domain "error_domain"
msgid "error 3"
msgstr "error 3 translation"
example% cat module2.po
default domain "messages.mo"
msgid "mesg 4"
msgstr "mesg 4 translation"
#
domain "error_domain"
msgid "error 5"
msgstr "error 5 translation"
#
domain "window_domain"
msgid "window 6"
msgstr "window 6 translation"
```

The following command will produce the output files `messages.mo`, `help_domain.mo`, and `error_domain.mo` in Solaris message catalog file format:

```
example% msgfmt module1.po
```

The following command will produce the output files `messages.mo`, `help_domain.mo`, `error_domain.mo`, and `window_domain.mo` in Solaris message catalog file format:

```
example% msgfmt module1.po module2.po
```

The following command will produce the output file `hello.mo` in Solaris message catalog file format:

```
example% msgfmt -o hello.mo module1.po module2.po
```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environmental variables that affect the execution of `msgfmt`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

msgfmt(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |
| CSI            | Enabled         |

**SEE ALSO** `xgettext(1)`, `gettext(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

**NOTES** Installing message catalogs under the C locale is pointless, since they are ignored for the sake of efficiency.

| <b>DESCRIPTION</b> | The <i>mt</i> utility sends commands to a magnetic tape drive. If -f <i>tapename</i> is not specified, the environment variable <i>TAPE</i> is used. If <i>TAPE</i> does not exist, <i>mt</i> uses the device <i>/dev/rmt/0n</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>     | The following option is supported:<br>-f <i>tapename</i> Specifies the raw tape device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPERANDS</b>    | The following operands are supported:<br><i>count</i> The number of times that the requested operation is to be performed. By default, <i>mt</i> performs <i>command</i> once. Multiple operations of <i>command</i> may be performed by specifying <i>count</i> .<br><i>command</i> Available commands that can be sent to a magnetic tape drive. Only as many characters as are required to uniquely identify a <i>command</i> need be specified.<br>eof, weof         Write <i>count</i> EOF marks at the current position on the tape.<br>fsf                Forward space over <i>count</i> EOF marks. The tape is positioned on the first block of the file.<br>fsr                Forward space <i>count</i> records.<br>bsf                Back space over <i>count</i> EOF marks. The tape is positioned on the beginning-of-tape side of the EOF mark.<br>bsr                Back space <i>count</i> records.<br>nbsf              Back space <i>count</i> files. The tape is positioned on the first block of the file. This is equivalent to <i>count+1</i> bsf's followed by one fsf.<br>asf                Absolute space to <i>count</i> file number. This is equivalent to a <i>rewind</i> followed by a fsf <i>count</i> .<br><br>If <i>count</i> is specified with any of the following commands, the <i>count</i> is ignored and the command is performed only once.<br>eom                Space to the end of recorded media on the tape. This is useful for appending files onto previously written tapes.<br>rewind             Rewind the tape. |

## mt(1)

|                               |                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>offline, rewoffl</code> | Rewind the tape and, if appropriate, take the drive unit off-line by unloading the tape. It cycles through all four tapes.                                  |
| <code>status</code>           | Print status information about the tape unit.                                                                                                               |
| <code>retension</code>        | Rewind the cartridge tape completely, then wind it forward to the end of the reel and back to beginning-of-tape to smooth out tape tension.                 |
| <code>reserve</code>          | Allow the tape drive to remain reserved after closing the device. The drive must then be explicitly released.                                               |
| <code>release</code>          | Re-establish the default behavior of releasing at close.                                                                                                    |
| <code>forcereserve</code>     | Break the reservation of the tape drive held by another host and then reserve the tape drive. This command can be executed only with super-user privileges. |
| <code>erase</code>            | Erase the entire tape. Erasing a tape may take a long time depending on the device and/or tape. Refer to the device specific manual for time details.       |

|                    |   |                                                                             |
|--------------------|---|-----------------------------------------------------------------------------|
| <b>EXIT STATUS</b> | 0 | All operations were successful.                                             |
|                    | 1 | Command was unrecognized or mt was unable to open the specified tape drive. |
|                    | 2 | An operation failed.                                                        |

**FILES** /dev/rmt/\* magnetic tape interface

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `tar(1)`, `tcopy(1)`, `ar(3HEAD)`, `environ(4)`, `attributes(5)`, `mtio(7I)`, `st(7D)`

**BUGS** | Not all devices support all options. Some options are hardware-dependent. Refer to the corresponding device manual page.

mt is architecture sensitive. Heterogeneous operation (that is, SPARC to IA or the reverse) is not supported.

| <b>NAME</b>        | mv – move files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>/usr/bin/mv [-fi] source target_file /usr/bin/mv [-fi] source... target_dir /usr/xpg4/bin/mv [-fi] source target_file /usr/xpg4/bin/mv [-fi] source... target_dir</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>In the first synopsis form, the mv utility moves the file named by the <i>source</i> operand to the destination specified by the <i>target_file</i>. <i>source</i> and <i>target_file</i> may not have the same name. If <i>target_file</i> does not exist, mv creates a file named <i>target_file</i>. If <i>target_file</i> exists, its contents are overwritten. This first synopsis form is assumed when the final operand does not name an existing directory.</p> <p>In the second synopsis form, mv moves each file named by a <i>source</i> operand to a destination file in the existing directory named by the <i>target_dir</i> operand. The destination path for each <i>source</i> is the concatenation of the target directory, a single slash character (/), and the last path name component of the <i>source</i>. This second form is assumed when the final operand names an existing directory.</p> <p>If mv determines that the mode of <i>target_file</i> forbids writing, it will print the mode (see <code>chmod(2)</code>), ask for a response, and read the standard input for one line. If the response is affirmative, the mv occurs, if permissible; otherwise, the command exits. Notice that the mode displayed may not fully represent the access permission if <i>target</i> is associated with an ACL. When the parent directory of <i>source</i> is writable and has the sticky bit set, one or more of the following conditions must be true:</p> <ul style="list-style-type: none"><li>■ the user must own the file</li><li>■ the user must own the directory</li><li>■ the file must be writable by the user</li><li>■ the user must be a privileged user</li></ul> <p>If <i>source</i> is a file and <i>target_file</i> is a link to another file with links, the other links remain and <i>target_file</i> becomes a new file.</p> <p>If <i>source</i> and <i>target_file/target_dir</i> are on different file systems, mv copies the source and deletes the original. Any hard links to other files are lost. mv will attempt to duplicate the source file characteristics to the target, that is, the owner and group id, permission modes, modification and access times, ACLs, and extended attributes, if applicable. For symbolic links, mv will preserve only the owner and group of the link itself.</p> <p>If unable to preserve owner and group id, mv will clear S_ISUID and S_ISGID bits in the target. mv will print a diagnostic message to stderr if unable to clear these bits, though the exit code will not be affected. mv may be unable to preserve extended attributes if the target file system does not have extended attribute support. /usr/xpg4/bin/mv will print a diagnostic message to stderr for all other failed attempts to duplicate file characteristics. The exit code will not be affected.</p> |

In order to preserve the source file characteristics, users must have the appropriate file access permissions. This includes being super-user or having the same owner id as the destination file.

**OPTIONS** The following options are supported:

- f mv will move the file(s) without prompting even if it is writing over an existing *target*. Note that this is the default if the standard input is not a terminal.
- i mv will prompt for confirmation whenever the move would overwrite an existing *target*. An affirmative answer means that the move should proceed. Any other answer prevents mv from overwriting the *target*.

**/usr/bin/mv** Specifying both the -f and the -i options is not considered an error. The -f option will override the -i option.

**/usr/xpg4/bin/mv** Specifying both the -f and the -i options is not considered an error. The last option specified will determine the behavior of mv.

**OPERANDS** The following operands are supported:

- source* A path name of a file or directory to be moved.
- target\_file* A new path name for the file or directory being moved.
- target\_dir* A path name of an existing directory into which to move the input files.

**USAGE** See *largefile(5)* for the description of the behavior of mv when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ENVIRONMENT VARIABLES** See *environ(5)* for descriptions of the following environment variables that affect the execution of mv: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS** The following exit values are returned:

- 0 All input files were moved successfully.
- >0 An error occurred.

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

**/usr/bin/mv**

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |

**NOTES** A `--` permits the user to mark explicitly the end of any command line options, allowing `mv` to recognize filename arguments that begin with a `-`. As an aid to BSD migration, `mv` will accept `-` as a synonym for `--`. This migration aid may disappear in a future release.

| <b>DESCRIPTION</b> | <p>The <code>/usr/bin/nawk</code> and <code>/usr/xpg4/bin/awk</code> utilities execute <i>programs</i> written in the <code>nawk</code> programming language, which is specialized for textual data manipulation. A <code>nawk program</code> is a sequence of patterns and corresponding actions. The string specifying <i>program</i> must be enclosed in single quotes (') to protect it from interpretation by the shell. The sequence of pattern - action statements can be specified in the command line as <i>program</i> or in one, or more, file(s) specified by the <code>-f progfile</code> option. When input is read that matches a pattern, the action associated with the pattern is performed.</p> <p>Input is interpreted as a sequence of records. By default, a record is a line, but this can be changed by using the <code>RS</code> built-in variable. Each record of input is matched to each pattern in the <i>program</i>. For each pattern matched, the associated action is executed.</p> <p>The <code>nawk</code> utility interprets each input record as a sequence of fields where, by default, a field is a string of non-blank characters. This default white-space field delimiter (blanks and/or tabs) can be changed by using the <code>FS</code> built-in variable or the <code>-F ERE</code> option. The <code>nawk</code> utility denotes the first field in a record <code>\$1</code>, the second <code>\$2</code>, and so forth. The symbol <code>\$0</code> refers to the entire record; setting any other field causes the reevaluation of <code>\$0</code>. Assigning to <code>\$0</code> resets the values of all fields and the <code>NF</code> built-in variable.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-F ERE</code>            Define the input field separator to be the extended regular expression <i>ERE</i>, before any input is read (can be a character).</li> <li><code>-f progfile</code>       Specifies the pathname of the file <i>progfile</i> containing a <code>nawk</code> program. If multiple instances of this option are specified, the concatenation of the files specified as <i>progfile</i> in the order specified is the <code>nawk</code> program. The <code>nawk</code> program can alternatively be specified in the command line as a single argument.</li> <li><code>-v assignment</code>    The <i>assignment</i> argument must be in the same form as an <i>assignment</i> operand. The assignment is of the form <i>var=value</i>, where <i>var</i> is the name of one of the variables described below. The specified assignment occurs before executing the <code>nawk</code> program, including the actions associated with <code>BEGIN</code> patterns (if any). Multiple occurrences of this option can be specified.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><i>program</i>            If no <code>-f</code> option is specified, the first operand to <code>nawk</code> is the text of the <code>nawk</code> program. The application supplies the <i>program</i> operand</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## nawk(1)

as a single argument to `nawk`. If the text does not end in a newline character, `nawk` interprets the text as if it did.

### *argument*

Either of the following two types of *argument* can be intermixed:

#### *file*

A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no *file* operands are specified, or if a *file* operand is `-`, the standard input is used.

#### *assignment*

An operand that begins with an underscore or alphabetic character from the portable character set, followed by a sequence of underscores, digits and alphabetic characters from the portable character set, followed by the `=` character specifies a variable assignment rather than a pathname. The characters before the `=` represent the name of a `nawk` variable; if that name is a `nawk` reserved word the behavior is undefined. The characters following the equal sign is interpreted as if they appeared in the `nawk` program preceded and followed by a double-quote (`"`) character, as a `STRING` token, except that if the last character is an unescaped backslash, it is interpreted as a literal backslash rather than as the first character of the sequence `"\"`. The variable is assigned the value of that `STRING` token. If the value is considered a *numericstring*, the variable is assigned its numeric value. Each such variable assignment is performed just before the processing of the following *file*, if any. Thus, an assignment before the first *file* argument is executed after the `BEGIN` actions (if any), while an assignment after the last *file* argument is executed before the `END` actions (if any). If there are no *file* arguments, assignments are executed before processing the standard input.

### INPUT FILES

Input files to the `nawk` program from any of the following sources:

- any *file* operands or their equivalents, achieved by modifying the `nawk` variables `ARGV` and `ARGC`
- standard input in the absence of any *file* operands
- arguments to the `getline` function

must be text files. Whether the variable `RS` is set to a value other than a newline character or not, for these files, implementations support records terminated with the specified separator up to `{LINE_MAX}` bytes and may support longer records.

If `-f progfile` is specified, the files named by each of the `progfile` option-arguments must be text files containing an `nawk` program.

The standard input are used only if no `file` operands are specified, or if a `file` operand is `-`.

## EXTENDED DESCRIPTION

A `nawk` program is composed of pairs of the form:

```
pattern { action }
```

Either the pattern or the action (including the enclosing brace characters) can be omitted. Pattern-action statements are separated by a semicolon or by a newline.

A missing pattern matches any record of input, and a missing action is equivalent to an action that writes the matched record of input to standard output.

Execution of the `nawk` program starts by first executing the actions associated with all `BEGIN` patterns in the order they occur in the program. Then each `file` operand (or standard input if no files were specified) is processed by reading data from the file until a record separator is seen (a newline character by default), splitting the current record into fields using the current value of `FS`, evaluating each pattern in the program in the order of occurrence, and executing the action associated with each pattern that matches the current record. The action for a matching pattern is executed before evaluating subsequent patterns. Last, the actions associated with all `END` patterns is executed in the order they occur in the program.

## Expressions in nawk

Expressions describe computations used in *patterns* and *actions*. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators are evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent any expression, while *lvalue* represents any entity that can be assigned to (that is, on the left side of an assignment operator).

| Syntax                 | Name            | Type of Result      | Associativity |
|------------------------|-----------------|---------------------|---------------|
| <code>( expr )</code>  | Grouping        | type of <i>expr</i> | n/a           |
| <code>\$expr</code>    | Field reference | string              | n/a           |
| <code>++ lvalue</code> | Pre-increment   | numeric             | n/a           |
| <code>-- lvalue</code> | Pre-decrement   | numeric             | n/a           |
| <code>lvalue ++</code> | Post-increment  | numeric             | n/a           |

| <i>lvalue</i> = <i>expr</i>  | Assignment                | type of <i>expr</i> | right         |

Each expression has either a string value, a numeric value or both. Except as stated for specific contexts, the value of an expression is implicitly converted to the type needed for the context in which it is used. A string value is converted to a numeric value by the equivalent of the following calls:

```
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer is converted to a string by the equivalent of a call to the `sprintf` function with the string `%d` as the `fmt` argument and the numeric value being converted as the first and only *expr* argument. Any other numeric value is converted to a string by the equivalent of a call to the `sprintf` function with the value of the variable `CONVFMT` as the `fmt` argument and the numeric value being converted as the first and only *expr* argument.

A string value is considered to be a *numeric string* in the following case:

1. Any leading and trailing blank characters is ignored.
2. If the first unignored character is a + or -, it is ignored.
3. If the remaining unignored characters would be lexically recognized as a `NUMBER` token, the string is considered a *numeric string*.

If a - character is ignored in the above steps, the numeric value of the *numeric string* is the negation of the numeric value of the recognized `NUMBER` token. Otherwise the numeric value of the *numeric string* is the numeric value of the recognized `NUMBER` token. Whether or not a string is a *numeric string* is relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero is treated as false and any other value is treated as true. Otherwise, a string value of the null string is treated as false and any other value is treated as true. A Boolean context is one of the following:

nawk(1)

- the first subexpression of a conditional expression.
- an expression operated on by logical NOT, logical AND, or logical OR.
- the second expression of a `for` statement.
- the expression of an `if` statement.
- the expression of the `while` clause in either a `while` or `do . . . while` statement.
- an expression used as a pattern (as in Overall Program Structure).

The nawk language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They are initially empty, and their sizes changes dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an *lvalue* and as an expression, as described in the grammar. Unsubscripted array names are used in only the following contexts:

- a parameter in a function definition or function call.
- the NAME token following any use of the keyword `in`.

A valid array *index* consists of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because nawk arrays are really one-dimensional, such a comma-separated list is converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the SUBSEP variable.

Thus, the following two index operations are equivalent:

```
var[expr1, expr2, ... exprn]
var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]
```

A multi-dimensioned *index* used with the `in` operator must be put in parentheses. The `in` operator, which tests for the existence of a particular array element, does not create the element if it does not exist. Any other reference to a non-existent array element automatically creates it.

## Variables and Special Variables

Variables can be used in an nawk program by referencing them. With the exception of function parameters, they are not explicitly declared. Uninitialized scalar variables and array elements have both a numeric value of zero and a string value of the empty string.

Field variables are designated by a `$` followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables are created by assigning a value to them. References to non-existent fields (that is, fields after `$NF`) produce the null string. However, assigning to a non-existent field (for example, `$(NF+2) = 5`) increases the value of `NF`, create any intervening fields with the null string as their values and cause the value of `$0` to be recomputed, with the fields being separated by the value of `OFS`. Each field variable has a string value when created. If

the string, with any occurrence of the decimal-point character from the current locale changed to a period character, is considered a *numeric string* (see Expressions in nawk above), the field variable also has the numeric value of the *numeric string*.

nawk sets the following special variables:

ARGC The number of elements in the ARGV array.

ARGV An array of command line arguments, excluding options and the *program* argument, numbered from zero to ARGC-1.

The arguments in ARGV can be modified or added to; ARGC can be altered. As each input file ends, nawk treats the next non-null element of ARGV, up to the current value of ARGC-1, inclusive, as the name of the next input file. Setting an element of ARGV to null means that it is not treated as an input file. The name - indicates the standard input. If an argument matches the format of an *assignment* operand, this argument is treated as an assignment rather than a *file* argument.

/usr/xpg4/bin/awk

CONVFMT The printf format for converting numbers to strings (except for output statements, where OFMT is used); % . 6g by default.

ENVIRON The variable ENVIRON is an array representing the value of the environment. The indices of the array are strings consisting of the names of the environment variables, and the value of each array element is a string consisting of the value of that variable. If the value of an environment variable is considered a *numeric string*, the array element also has its numeric value.

In all cases where nawk behavior is affected by environment variables (including the environment of any commands that nawk executes via the system function or via pipeline redirections with the print statement, the printf statement, or the getline function), the environment used is the environment at the time nawk began executing.

FILENAME A pathname of the current input file. Inside a BEGIN action the value is undefined. Inside an END action the value is the name of the last input file processed.

FNR The ordinal number of the current record in the current file. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed in the last file processed.

FS Input field separator regular expression; a space character by default.

NF The number of fields in the current record. Inside a BEGIN action, the use of NF is undefined unless a getline function without a var argument is executed previously. Inside an END action, NF retains the value it had for the last record read, unless a

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | subsequent, redirected, <code>getline</code> function without a <i>var</i> argument is performed prior to entering the <code>END</code> action.                                                                                                                                                                                                                                                                                                                                                     |
| NR     | The ordinal number of the current record from the start of input. Inside a <code>BEGIN</code> action the value is zero. Inside an <code>END</code> action the value is the number of the last record processed.                                                                                                                                                                                                                                                                                     |
| OFMT   | The <code>printf</code> format for converting numbers to strings in output statements <code>"%.6g"</code> by default. The result of the conversion is unspecified if the value of <code>OFMT</code> is not a floating-point format specification.                                                                                                                                                                                                                                                   |
| OFS    | The <code>print</code> statement output field separator; a space character by default.                                                                                                                                                                                                                                                                                                                                                                                                              |
| ORS    | The <code>print</code> output record separator; a newline character by default.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| LENGTH | The length of the string matched by the <code>match</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RS     | The first character of the string value of <code>RS</code> is the input record separator; a newline character by default. If <code>RS</code> contains more than one character, the results are unspecified. If <code>RS</code> is null, then records are separated by sequences of one or more blank lines: leading or trailing blank lines do not produce empty records at the beginning or end of input, and the field separator is always newline, no matter what the value of <code>FS</code> . |
| RSTART | The starting position of the string matched by the <code>match</code> function, numbering from 1. This is always equivalent to the return value of the <code>match</code> function.                                                                                                                                                                                                                                                                                                                 |
| SUBSEP | The subscript separator string for multi-dimensional arrays; the default value is 1                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Regular Expressions**

The `nawk` utility makes use of the extended regular expression notation (see `regex(5)`) except that it allows the use of C-language conventions to escape special characters within the EREs, namely `\\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, and those specified in the following table. These escape sequences are recognized both inside and outside bracket expressions. Note that records need not be separated by newline characters and string constants can contain newline characters, so even the `\n` sequence is valid in `nawk` EREs. Using a slash character within the regular expression requires escaping as shown in the table below:

| Escape Sequence | Description              | Meaning                  |
|-----------------|--------------------------|--------------------------|
| <code>\"</code> | Backslash quotation-mark | Quotation-mark character |
| <code>\/</code> | Backslash slash          | Slash character          |

|                   |                                                                                                                                                                                                                                                      |                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\ddd</code> | A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NULL character), the behavior is undefined.                              | The character encoded by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences, including the leading <code>\</code> for each byte. |
| <code>\c</code>   | A backslash character followed by any character not described in this table or special characters ( <code>\\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code> ). | Undefined                                                                                                                                                                                        |

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, `~` and `! ~`. These operators interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the `~` expression evaluates to the value 1, and the `! ~` expression evaluates to the value 0. If the regular expression does not match the string, the `~` expression evaluates to the value 0, and the `! ~` expression evaluates to the value 1. If the right-hand operand is any expression other than the lexical token `ERE`, the string value of the expression is interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions also are applied in the determining the value of a string literal (the lexical token `STRING`), and is applied a second time when a string literal is used in this context.

When an `ERE` token appears as an expression in any context other than as the right-hand of the `~` or `! ~` operator or as one of the built-in function arguments described below, the value of the resulting expression is the equivalent of:

```
$0 ~ /ere/
```

The `ere` argument to the `gsub`, `match`, `sub` functions, and the `fs` argument to the `split` function (see `String Functions`) is interpreted as extended regular expressions. These can be either `ERE` tokens or arbitrary expressions, and are interpreted in the same manner as the right-hand side of the `~` or `! ~` operator.

An extended regular expression can be used to separate fields by using the `-F ERE` option or by assigning a string containing the expression to the built-in variable `FS`. The default value of the `FS` variable is a single space character. The following describes `FS` behavior:

1. If `FS` is a single character:
  - If `FS` is the space character, skip leading and trailing blank characters; fields are delimited by sets of one or more blank characters.
  - Otherwise, if `FS` is any other character `c`, fields are delimited by each single occurrence of `c`.

nawk(1)

2. Otherwise, the string value of `FS` is considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression delimits fields.

Except in the `gsub`, `match`, `split`, and `sub` built-in functions, regular expression matching is based on input records; that is, record separator characters (the first character of the value of the variable `RS`, a newline character by default) cannot be embedded in the expression, and no expression matches the record separator character. If the record separator is not a newline character, newline characters embedded in the expression can be matched. In those four built-in functions, regular expression matching are based on text strings. So, any character (including the newline character and the record separator) can be embedded in the pattern and an appropriate pattern will match any character. However, in all `nawk` regular expression matching, the use of one or more NUL characters in the pattern, input record or text string produces undefined results.

**Patterns** A *pattern* is any valid *expression*, a range specified by two expressions separated by comma, or one of the two special patterns `BEGIN` or `END`.

**Special Patterns** The `nawk` utility recognizes two special patterns, `BEGIN` and `END`. Each `BEGIN` pattern is matched once and its associated action executed before the first record of input is read (except possibly by use of the `getline` function in a prior `BEGIN` action) and before command line assignment is done. Each `END` pattern is matched once and its associated action executed after the last record of input has been read. These two patterns have associated actions.

`BEGIN` and `END` do not combine with other patterns. Multiple `BEGIN` and `END` patterns are allowed. The actions associated with the `BEGIN` patterns are executed in the order specified in the program, as are the `END` actions. An `END` pattern can precede a `BEGIN` pattern in a program.

If an `nawk` program consists of only actions with the pattern `BEGIN`, and the `BEGIN` action contains no `getline` function, `nawk` exits without reading its input when the last statement in the last `BEGIN` action is executed. If an `nawk` program consists of only actions with the pattern `END` or only actions with the patterns `BEGIN` and `END`, the input is read before the statements in the `END` actions are executed.

**Expression Patterns** An expression pattern is evaluated as if it were an expression in a Boolean context. If the result is true, the pattern is considered to match, and the associated action (if any) is executed. If the result is false, the action is not executed.

**Pattern Ranges** A pattern range consists of two expressions separated by a comma. In this case, the action is performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.

**Actions** An action is a sequence of statements. A statement may be one of the following:

```
if (expression) statement [else statement]
while (expression) statement
```

```

do statement while (expression)
for (expression ; expression ; expression) statement
for (var in array) statement
delete array[subscript] #delete an array element
break
continue
{ [statement] . . . }
expression # commonly variable = expression
print [expression-list] [>expression]
printf format [,expression-list] [>expression]
next # skip remaining patterns on this input line
exit [expr] # skip the rest of the input; exit status is expr
return [expr]

```

Any single statement can be replaced by a statement list enclosed in braces. The statements are terminated by newline characters or semicolons, and are executed sequentially in the order that they appear.

The next statement causes all further processing of the current input record to be abandoned. The behavior is undefined if a next statement appears or is invoked in a BEGIN or END action.

The exit statement invokes all END actions in the order in which they occur in the program source and then terminate the program without reading further input. An exit statement inside an END action terminates the program without further execution of END actions. If an expression is specified in an exit statement, its numeric value is the exit status of nawk, unless subsequent errors are encountered or a subsequent exit statement with an expression is executed.

## Output Statements

Both print and printf statements write to standard output by default. The output is written to the location specified by *output\_redirection* if one is supplied, as follows:

```
> expression>> expression| expression
```

In all cases, the *expression* is evaluated to produce a string that is used as a full pathname to write into (for > or >>) or as a command to be executed (for |). Using the first two forms, if the file of that name is not currently open, it is opened, creating it if necessary and using the first form, truncating the file. The output then is appended to the file. As long as the file remains open, subsequent calls in which *expression* evaluates to the same string value simply appends output to the file. The file remains open until the close function, which is called with an expression that evaluates to the same string value.

The third form writes output onto a stream piped to the input of a command. The stream is created if no stream is currently open with the value of *expression* as its command name. The stream created is equivalent to one created by a call to the popen(3C) function with the value of *expression* as the *command* argument and a value of w as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value writes output to the existing stream. The stream will remain open until the close function is called with an expression that evaluates to the same string value. At that time, the stream is closed as if by a call to the pclose function.

## nawk(1)

These output statements take a comma-separated list of *expression s* referred in the grammar by the non-terminal symbols `expr_list`, `print_expr_list` or `print_expr_list_opt`. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The `print` statement writes the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable `OFS` above), and terminated by the output record separator (see variable `ORS` above). All expression arguments is taken as strings, being converted if necessary; with the exception that the `printf` format in `OFMT` is used instead of the value in `CONVFMT`. An empty expression list stands for the whole input record (`$0`).

The `printf` statement produces output based on a notation similar to the File Format Notation used to describe file formats in this document. Output is produced as specified with the first expression argument as the string *format* and subsequent expression arguments as the strings *arg1* to *argn*, inclusive, with the following exceptions:

1. The *format* is an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The space character in the *format* string, in any context other than a *flag* of a conversion specification, is treated as an ordinary character that is copied to the output.
2. If the character set contains a Delta character and that character appears in the *format* string, it is treated as an ordinary character that is copied to the output.
3. The *escape sequences* beginning with a backslash character is treated as sequences of ordinary characters that are copied to the output. Note that these same sequences is interpreted lexically by `nawk` when they appear in literal strings, but they is not treated specially by the `printf` statement.
4. A *field width* or *precision* can be specified as the `*` character instead of a digit string. In this case the next argument from the expression list is fetched and its numeric value taken as the field width or precision.
5. The implementation does not precede or follow output from the `d` or `u` conversion specifications with blank characters not specified by the *format* string.
6. The implementation does not precede output from the `o` conversion specification with leading zeros not specified by the *format* string.
7. For the `c` conversion specification: if the argument has a numeric value, the character whose encoding is that value is output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value will be output; if the string does not contain any characters the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument will be evaluated. With the exception of the `c` conversion, the value will be converted to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.

10. If any character sequence in the *format* string begins with a % character, but does not form a valid conversion specification, the behavior is unspecified.

Both `print` and `printf` can output at least `{LINE_MAX}` bytes.

**Functions** The nawk language has a variety of built-in functions: arithmetic, string, input/output and general.

**Arithmetic Functions** The arithmetic functions, except for `int`, are based on the ISO C standard. The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `[ ]` brackets), such use is undefined.

`atan2(y,x)` Return arctangent of  $y/x$ .

`cos(x)` Return cosine of  $x$ , where  $x$  is in radians.

`sin(x)` Return sine of  $x$ , where  $x$  is in radians.

`exp(x)` Return the exponential function of  $x$ .

`log(x)` Return the natural logarithm of  $x$ .

`sqrt(x)` Return the square root of  $x$ .

`int(x)` Truncate its argument to an integer. It will be truncated toward 0 when  $x > 0$ .

`rand()` Return a random number  $n$ , such that  $0 \leq n < 1$ .

`srand([expr])` Set the seed value for `rand` to *expr* or use the time of day if *expr* is omitted. The previous seed value will be returned.

**String Functions** The string functions in the following list shall be supported. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `[ ]` brackets), such use is undefined.

`gsub(ere,repl[,in])` Behave like `sub` (see below), except that it will replace all occurrences of the regular expression (like the `ed` utility global substitute) in `$0` or in the *in* argument, when specified.

`index(s,t)` Return the position, in characters, numbering from 1, in string *s* where string *t* first occurs, or zero if it does not occur at all.

`length[([s])]`  Return the length, in characters, of its argument taken as a string, or of the whole record, `$0`, if there is no argument.

## nawk(1)

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>match(s,ere)</code>               | Return the position, in characters, numbering from 1, in string <i>s</i> where the extended regular expression <i>ere</i> occurs, or zero if it does not occur at all. <code>RSTART</code> will be set to the starting position (which is the same as the returned value), zero if no match is found; <code>RLENGTH</code> will be set to the length of the matched string, -1 if no match is found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>split(s,a[,fs])</code>            | Split the string <i>s</i> into array elements <i>a</i> [1], <i>a</i> [2], . . . , <i>a</i> [ <i>n</i> ], and return <i>n</i> . The separation will be done with the extended regular expression <i>fs</i> or with the field separator <code>FS</code> if <i>fs</i> is not given. Each array element will have a string value when created. If the string assigned to any array element, with any occurrence of the decimal-point character from the current locale changed to a period character, would be considered a <i>numeric string</i> ; the array element will also have the numeric value of the <i>numeric string</i> . The effect of a null string as the value of <i>fs</i> is unspecified.                                                                                                                                                                                                                                            |
| <code>sprintf(fmt,expr,expr,...)</code> | Format the expressions according to the <code>printf</code> format given by <i>fmt</i> and return the resulting string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>sub(ere,repl[, in])</code>        | Substitute the string <i>repl</i> in place of the first instance of the extended regular expression <i>ERE</i> in string <i>in</i> and return the number of substitutions. An ampersand ( <code>&amp;</code> ) appearing in the string <i>repl</i> will be replaced by the string from <i>in</i> that matches the regular expression. For each occurrence of backslash ( <code>\</code> ) encountered when scanning the string <i>repl</i> from beginning to end, the next character is taken literally and loses its special meaning (for example, <code>\&amp;</code> will be interpreted as a literal ampersand character). Except for <code>&amp;</code> and <code>\</code> , it is unspecified what the special meaning of any such character is. If <i>in</i> is specified and it is not an <i>lvalue</i> the behavior is undefined. If <i>in</i> is omitted, <code>nawk</code> will substitute in the current record ( <code>\$0</code> ) . |

|                               |                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>substr(s,m[, n])</code> | Return the at most <i>n</i> -character substring of <i>s</i> that begins at position <i>m</i> , numbering from 1. If <i>n</i> is missing, the length of the substring will be limited by the length of the string <i>s</i> .                                                                                                                                                          |
| <code>tolower(s)</code>       | Return a string based on the string <i>s</i> . Each character in <i>s</i> that is an upper-case letter specified to have a <code>tolower</code> mapping by the <code>LC_CTYPE</code> category of the current locale will be replaced in the returned string by the lower-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string. |
| <code>toupper(s)</code>       | Return a string based on the string <i>s</i> . Each character in <i>s</i> that is a lower-case letter specified to have a <code>toupper</code> mapping by the <code>LC_CTYPE</code> category of the current locale will be replaced in the returned string by the upper-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string.  |

All of the preceding functions that take *ERE* as a parameter expect a pattern or a string valued expression that is a regular expression as defined below.

## Input/Output and General Functions

The input/output and general functions are:

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>close (expression)</code>        | Close the file or pipe opened by a <code>print</code> or <code>printf</code> statement or a call to <code>getline</code> with the same string-valued <i>expression</i> . If the close was successful, the function will return 0; otherwise, it will return non-zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>expression   getline[var]</code> | Read a record of input from a stream piped from the output of a command. The stream will be created if no stream is currently open with the value of <i>expression</i> as its command name. The stream created will be equivalent to one created by a call to the <code>popen</code> function with the value of <i>expression</i> as the <i>command</i> argument and a value of <code>r</code> as the <i>mode</i> argument. As long as the stream remains open, subsequent calls in which <i>expression</i> evaluates to the same string value will read subsequent records from the file. The stream will remain open until the <code>close</code> function is called with an expression that evaluates to the same string value. At |

|                                            | <p>that time, the stream will be closed as if by a call to the <code>pclose</code> function. If <i>var</i> is missing, <code>\$0</code> and <code>NF</code> will be set; otherwise, <i>var</i> will be set.</p> <p>The <code>getline</code> operator can form ambiguous constructs when there are operators that are not in parentheses (including concatenate) to the left of the <code> </code> (to the beginning of the expression containing <code>getline</code>). In the context of the <code>\$</code> operator, <code> </code> behaves as if it had a lower precedence than <code>\$</code>. The result of evaluating other operators is unspecified, and all such uses of portable applications must be put in parentheses properly.</p>                                                                                                                                                                                                                                                                                                             |
| <code>getline</code>                       | <p>Set <code>\$0</code> to the next input record from the current input file. This form of <code>getline</code> will set the <code>NF</code>, <code>NR</code>, and <code>FNR</code> variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>getline var</code>                   | <p>Set variable <i>var</i> to the next input record from the current input file. This form of <code>getline</code> will set the <code>FNR</code> and <code>NR</code> variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>getline [var] &lt; expression</code> | <p>Read the next record of input from a named file. The <i>expression</i> will be evaluated to produce a string that is used as a full pathname. If the file of that name is not currently open, it will be opened. As long as the stream remains open, subsequent calls in which <i>expression</i> evaluates to the same string value will read subsequent records from the file. The file will remain open until the <code>close</code> function is called with an expression that evaluates to the same string value. If <i>var</i> is missing, <code>\$0</code> and <code>NF</code> will be set; otherwise, <i>var</i> will be set.</p> <p>The <code>getline</code> operator can form ambiguous constructs when there are binary operators that are not in parentheses (including concatenate) to the right of the <code>&lt;</code> (up to the end of the expression containing the <code>getline</code>). The result of evaluating such a construct is unspecified, and all such uses of portable applications must be put in parentheses properly.</p> |

`system(expression)`

Execute the command given by *expression* in a manner equivalent to the `system(3C)` function and return the exit status of the command.

All forms of `getline` will return 1 for successful input, 0 for end of file, and -1 for an error.

Where strings are used as the name of a file or pipeline, the strings must be textually identical. The terminology “same string value” implies that “equivalent strings”, even those that differ only by space characters, represent different files.

### User-defined Functions

The nawk language also provides user-defined functions. Such functions can be defined as:

```
function name(args, . . .) { statements }
```

A function can be referred to anywhere in an nawk program; in particular, its use can precede its definition. The scope of a function will be global.

Function arguments can be either scalars or arrays; the behavior is undefined if an array name is passed as an argument that the function uses as a scalar, or if a scalar expression is passed as an argument that the function uses as an array. Function arguments will be passed by value if scalar and by reference if array name. Argument names will be local to the function; all other variable names will be global. The same name will not be used as both an argument name and as the name of a function or a special nawk variable. The same name must not be used both as a variable name with global scope and as the name of a function. The same name must not be used within the same scope both as a scalar variable and as an array.

The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars will be initialized with a string value of the null string and a numeric value of zero, and the extra parameters that are used in the function body as arrays will be initialized as empty arrays. If more arguments are supplied in a function call than are in the function definition, the behavior is undefined.
