

The Internet Registry Information Service (IRIS) Protocol

January 12, 2005

Marcos Sanz, DeNIC
Andrew Newton, VeriSign
Leslie Daigle, VeriSign

Background

- The IETF's CRISP Working Group
 - CRISP - Cross-Registry Internet Service Protocol
 - The CRISP Working Group was tasked with finding a solution to the problems that currently infest the Nicname/Whois protocol.
 - The CRISP Working Group created a list of functional requirements.
 - Proposals meeting these requirements were evaluated.
 - IRIS was selected as the protocol to publish as a standard.
- Now an IETF Proposed Standard
 - RFCs 3981, 3982, 3983

Flexible and Extensible

- Registry types within CRISP
 - Domain Registries (thin and thick).
 - Domain Registrars.
 - Number Resource Registries (RIRs).
 - Before CRISP, domain and IP address WHOIS were on divergent paths.
- Outside of CRISP
 - EREG - IRIS for ENUM (work-item of ENUM working group).
 - ECRIT - Emergency Context Resolution for Internet Technology (emergency calls and messaging).
 - NGN (ITU, ETSI, ATIS)

Value

- Decentralized by design.
 - Registrars can keep their data to themselves.
- Navigation.
 - Uses DNS hierarchies where possible.
 - Distinguishes between entity references and search continuations.
 - Entity references are akin to URLs
 - Search continuations are – “restart the search at this different site”
- Multiple authentication mechanisms.
 - Enables better policies surrounding the exposure of whois data.
- Internationalization and IDN Support.
- etc...

Cost

- Open Standard
 - There is no IPR attached to IRIS.
 - No specific implementation necessary.
- Implementation
 - Uses common techniques and components.
 - XML, NAPTR & SRV RRs
 - Open source client and server implementations available.
- Database
 - IRIS is intended to sit atop current registration databases.
 - It does not change a registry's or registrar's database.
 - Because that can be really expensive.
 - IRIS imposes no matrices or tree structures requiring new back-end data models.

CRISP Status

- All of CRISP's original milestones have now been met:
 - Requirements (RFC 3707)
 - Core Protocol and Domain Registry (RFCs 3981, 3982, and 3983)
- Address Registry
 - To be last called in CRISP soon.
- IRIS over UDP, DCHK
 - To be last called in CRISP soon.

Other Work Items

- WHOIS (port 43) cohabitation
 - Dovetails nicely with work already done by DeNIC on SRV records and Whois
 - No changes to existing whois servers.
 - Enables clients to integrate the two services.

Known Deployments

- Current
 - .com/.net (see iris.verisignlabs.com)
 - UDP planned for 2005
- In 2005
 - .de
 - .uk
 - RIPE NCC
- .de, .uk, .com, .net represent over 60% of all registered domains.

Navigation of Servers and Data

- Finding the best server to query first using SRV and NAPTR records within DNS.
 - Use of DNS means there is no need for a “well-known” server.
- Query Distribution with entity references and search continuations.
 - Registries may point to registrars.
 - Registrars may point to registrants.
- New navigation methods may be added.

Tiered Access

- Ability to control who gets the information.
 - Policy determines who sees what.
- Coordination can be in-band, out-of-band, or both.
- Adds many more policy options than are available with port 43.

```
$iris kosters.net

  US

$iris -cert fbi.cert kosters.net
  Kusters, Mark
  13121 Fox Shadow Lane
  Clifton, VA 20124 US
  703-948-3362
```

Authentication Distribution

- One of the challenges with tiered access is giving the right users access to the right information without overburdening the servers with the constant need to sync user lists.
- Digital certificates can off-load this burden.
 - Chains of trust.
 - A sender doesn't know the specific user, but does trust the entity that issued the certificate to the user.
 - User-based attributes.
 - A sender doesn't know the specific user, but trusts that a user of a certain type based on data in the certificate.
- “Relay Bags” also allow off-loading for authorization schemes to a policy server.

Policy Neutral

- IRIS is policy neutral.
 - Access can be anonymous and/or authenticated.
 - Data can be given to some users and/or not others.
 - Trust can be based locally, regionally, globally, or all of the above.
 - Information can be centralized, distributed, or centrally indexed but distributed or all of the above.
- Since policy is not in the protocol, it can be differ between servers or sets of servers.
- Policy makers now have more tools.

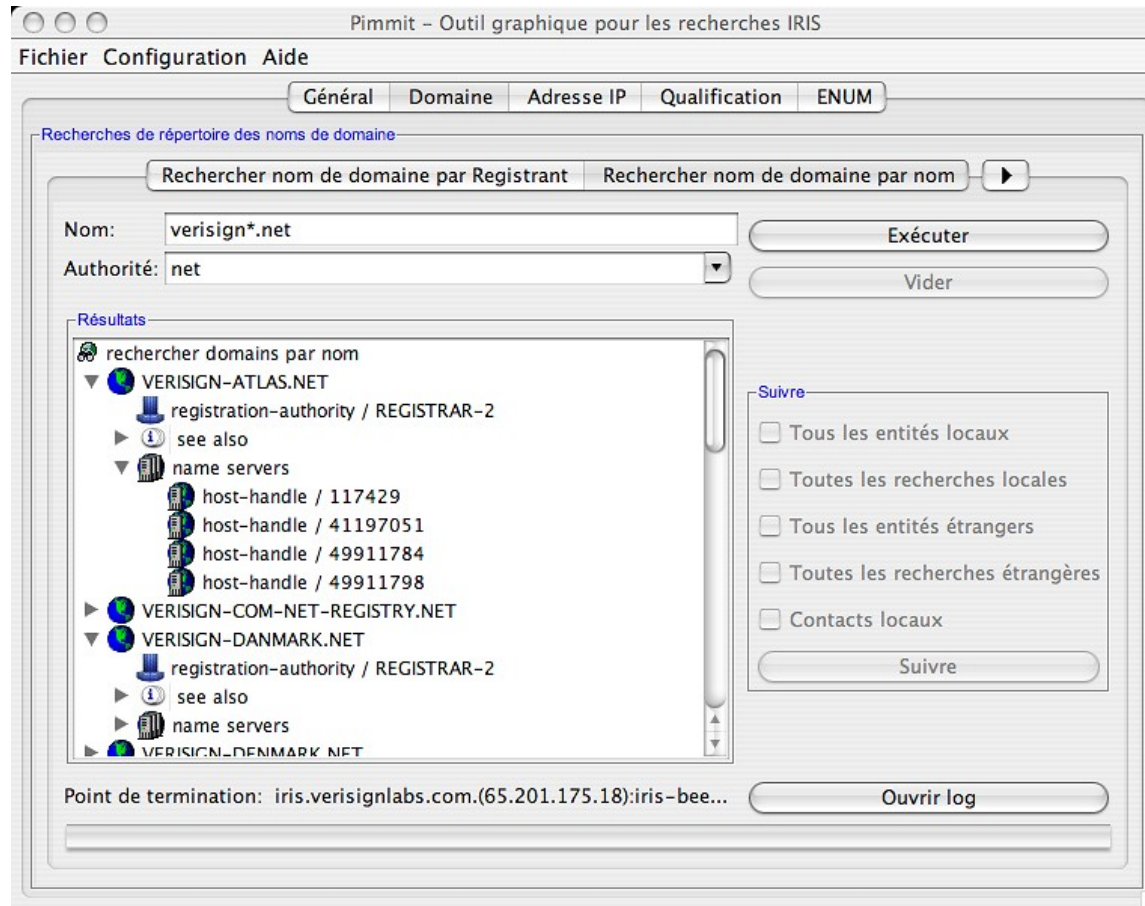

Well Structured

- Well-known queries.
 - Better server performance on database indices.
 - Better client interface.
- Structured and Normalized Data
 - Enables L10N or I18N protocol elements.
 - Richer client presentation.
 - Location of entities are clearly identified.
 - Relation to the query is clearly noted.
- When combined with authentication, enables detailed audit trails.

Structure & Internationalization

- The content of the data is under the control of the server.
- The presentation of the data is under the control of the client.

Localization

- For Internationalization:
 - datatypes are given well known tags for localization by the clients
 - data with multiple locales are given language tags

The image shows two screenshots of network management software. The left screenshot displays a table of network details for the IPv4 handle NET-172-12-14. The right screenshot shows the search results for the same handle, with localized labels in French. A red circle highlights the first four rows in both windows, and a red line connects the circles, illustrating the mapping between the data and its localized labels.

Name	Value
Authority	localhost:3434
Registry Type	areg1
Entity Class	ipv4-handle
Entity Name	NET-172-12-14
Type	ipv4Network
IPv4 Network Handle	NET-172-12-14
name	European Block
CIDR address	172.12.0.0/14
start address	172.12.0.0
end address	172.15.255.255
network type	Reserved
organization	1
registration date	1999-07-01T04:00:00Z
last updated date	2003-06-22T04:00:00Z

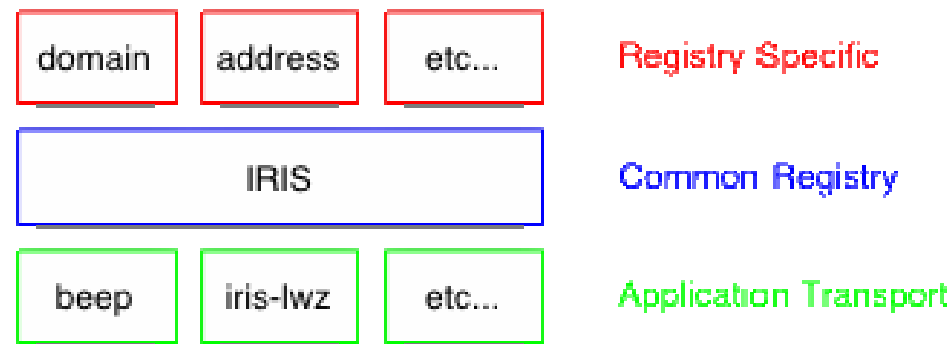

Search Results (Localized Labels):

Nom
Autorité
Type de répertoire
Classe d'entité
Nom d'entité
Type
IPv4 Network Handle
nom
Adresse CIDR
adresse initial
adresse final
type de réseau
organisation
date d'enregistrement
date de dernière modification

Extensibility Through Layering

- IRIS is a layered protocol
 - Clear lines of responsibility in each layer.
 - Makes re-use of components simple.
- Common Building Components
 - XML, NAPTR & SRV records, SASL

Conclusion

- IRIS Core & DREG are standardized.
 - Work is proceeding in other areas.
- Benefits
 - Decentralization with Navigation
 - Better policy support via multiple authentication
 - Structure and Internationalization
 - Extensible
- Low Cost
 - Bolts atop existing databases.
 - Authorization management.
 - Open source implementations available.

Follow-Up

- If you have additional questions or concerns to be addressed, please feel free to contact us:
 - Marcos Sanz sanz@denic.de
 - Andrew Newton andy@hxr.us
 - Leslie Daigle leslie@thinkingcat.com
- Or ask the CRISP working group:
 - crisp@ietf.org
