Abstract

Significant progress has been made in the hyphenation ability of T_EX since its first version in 1978. However, in practice, we still face problems in many languages such as Czech, German, Swedish etc. when trying to adopt local typesetting industry standards.

In this paper we discuss problems of hyphenation in multilingual documents in general, we show how we've made Czech and Slovak hyphenation patterns, and we describe our results achieved using the program PATGEN for hyphenation pattern generation. We show that hyphenation of compound words may be partially solved even within the scope of T_EX82. We discuss possible enhancements of the process of hyphenation pattern generation and describe features that might be reasonable to think about to be incorporated in Ω or another successor to T_EX82.

Motivation

> *"Go forth and make masterpieces*
> *of hyphenation patterns . . . "*
> *(Haralambous, 1994)*

Editors' and publishers' typographical requirements for camera-ready prepared documents are growing. To meet some of their requirements in T_EX, especially when typesetting in narrow columns, one needs perfect hyphenation patterns in order to find almost all permissible hyphenation points.

When making Czech hyphenation patterns and typesetting multilingual documents we encountered some problems with achieving quality hyphenation and decent-looking documents with T_EX. This work has led to our ideas about possible remedies and future extensions in a successor to T_EX.

Our paper consists of three parts. In the first part we try to summarize the developments that have been made on the issue since T_EX's birth.

In the second, we describe our attempts to create Czech and Slovak hyphenation patterns and summarize hints and suggestions for PATGEN users.

In the third part we discuss possible improvements that might take place in a T_EX successor (Ω, ε-T_EX or New Typesetting System ($\mathcal{N}\mathcal{T}\mathcal{S}$)).

The hyphenation story

Let's review the developments in hyphenation in T_EX that have been made so far.

English In T_EX78 a rule-driven algorithm for English was built-in by Liang and Knuth. Their algorithm found 40 % of the allowable hyphens, with about 1 % error (Liang, 1981). Although authors claimed that these results are "quite good", Liang continued working on the generalization of the idea of rules expressed by hyphenating and inhibiting patterns. In his dissertation (Liang, 1983) he describes a method, which is used in T_EX82, based on the generalization of the prefix, suffix and the vowel-consonant-consonant-vowel rules. He wrote (in WEB) the program PATGEN (Liang and Breitenlohner, 1991) to automate the process of pattern generation from a set of already hyphenated words.

---

* Reprinted with corrections from EuroT_EX' 94 proceedings, Gdańsk, pp. 59–68 with permission.

He started with the 1966 edition of Webster's Pocket Dictionary that included hyphenated words and inflections (about 50 000 entries in total). In the early stages, testing the algorithm on a 115 000 word dictionary from the publisher, 10 000 errors in words not occurring in the pocket dictionary were found. "Most of these were specialized technical terms that we decided not to worry about, but a few hundred were embarrasing enough that we decided to add them to the word list." (Liang, 1983, p. 30). He reports the following figures: 89,3 % permissible hyphens found in the *input* word-list with 4447 patterns with 14 exceptions.

Liang's method is described by Knuth (1986b, Appendix H) and was later adopted in many programs such as `troff` (Emerson and Paulsell, 1987) and `Lout`, and in localizations of today's WYSIWYG DTP systems such as QuarkXPress, Ventura, etc. Although specialized dictionaries such as Allen's (1990) by Oxford University Press separate possible word-division points into at least two categories (preferred and less recommended), we have not seen any program that incorporates the possibility of taking into account these classes of hyphenation points so far.

Those other languages

> "... patterns are supposed to be prepared by experts who are paid well for their expertise."
> (Knuth, 1986b, p. 453, 8th printing)

The first version of T_EX82 allowed only one set of patterns to be loaded at a time. Thus it was not possible to typeset multilingual documents with correct hyphenation in all languages and this limitation was quite unsatisfactory. Already in 1985, two attempts to solve the problem were made:

Multilingual T_EX: Extensions, most of which afterwards Knuth adopted in T_EX 3.x were suggested and implemented by Ferguson (1985). A new primitive `\language`[1] was introduced for switching between several sets of `\patterns` and hyphenation exceptions. A new `\charsubdef` primitive is still used in today's 8-bit implementations of T_EX. Full details are give by Ferguson (1988).

_IS^IT_EX: Barth and Nirschl (1985) presented an approach on achieving decent hyphenation in German texts under the name S^IT_EX, or in its interactive version under the name _IS^IT_EX. Their method, (available as a change file for UNIXT_EX from `eiunix.tuwien.ac.at`) has been used

in Germany for years and is being improved (Barth and Steiner, 1992; Barth, Steiner, and Herbeck, 1993). This approach has been proposed for inclusion in $\mathcal{NTS}$ (NTS-L, 1992–).

S^IT_EX (_IS^IT_EX for the interactive version) introduces a new primitive `\nebenpenalty` which allows differentiation between main (compound word boundaries) and secondary (word stem) hyphenation points.

A new notation for hyphenation patterns is introduced and a hyphenation algorithm for German is hardwired into the program. The tables for the algorithm, file `sihyphen.tex` (60K) are written manually and can be simply edited and enriched. However, no provision for the generation of these patterns from a word-list (such as the `PATGEN` program) is offered.

During the last 15 years almost every year there appeared a paper in *TUGboat* reporting new patterns for some language (see table 1). Another couple of hyphenation patterns, fonts and preprocessors are available in ScholarT_EX[2] (Haralambous, 1991).

Although Don Knuth introduced the new primitives `\language` and `\setlanguage` for switching between several sets of hyphenation patterns in T_EX 3.0, there are indications that not all of the related problems have been solved and further investigations are necessary (Fanton, 1991).

Proposals on how to customize T_EX for a new language were suggested by Partl (1990). New tools to simplify the generation of 8-bit (virtual) fonts were designed — `fontinst` (Jeffrey, 1993) and `accents` (Zlatuška, 1991). A macro package for simple language switching, `babel` (Braams, 1991a; Braams, 1991b; Braams, 1993), was produced to simplify typesetting of multilingual documents. An international version of the `Makeindex` program was written (Schrod, 1991). The DC fonts (Ferguson, 1990; Haralambous, 1992a; Haralambous, 1993a), designed to permit hyphenation in many languages, are now being widely distributed, forced by the new LAT_EX wave. Compliance with the suggestions of the working group TWGMLC[3] (Haralambous, 1992a) could help too (naming conventions for hyphenation files, etc.). Multilingual document aspects of typesetting are being collected in the scope of LAT_EX3 project in (Gaulle, 1994), where a nice collection of language-related T_EX primitives can be found, together with definitions of the terminology used.

---

[1] A rather misleading name, as it deals with only one particular feature of a language — hyphenation — which feature is of only limited interest to linguists.

Exception logs

> *"If any computer center decides to preload different exceptions from those in plain TeX (i.e., in the file `HYPHEN.TEX`), the changed exceptions should not under any circumstances be put into `HYPHEN.TEX` or `PLAIN.TEX`. All local changes should go into a separate file, so that TeX will still produce identical results on all machines. In fact, I recommend not preloading those changes, but rather assuming that individual users will have their own favorite collection of updates to the standard format files."*
>
> *(Knuth, 1983)*

The exception log and corrections for US English hyphenation have been reported several times – (e.g. Thulin, 1987; Beeton, 1989; Kuiken, 1990; Beeton, 1992), as shown in table 2. These listings are published in accordance with DEK's wish (Knuth, 1983). Only words with *wrongly* placed hyphenation points are listed, not those where TeX finds only a subset of possible breakpoints.

Table 2: Growing number of exceptions for `hyphen.tex`

# of exceptions	where reported
14	(Liang, 1983)
24	(Beeton, 1984, *TUGboat* 5, no. 1)
88	(Beeton, 1985, *TUGboat* 6, no. 3)
127	(Beeton, 1986, *TUGboat* 7, no. 3)
129	(Thulin, 1987, *TUGboat* 8, no. 1)
501	(Beeton, 1989, *TUGboat* 10, no. 3)
543	(Beeton, 1992, *TUGboat* 13, no. 4)

This shows that significant care and effort is still needed and *is being gradually spent* on the checking of hyphenation points during proof-reading and that the standard US patterns are not sufficient to satisfy current needs. Additional sets of patterns (2 versions – `ushyphen.add` and `ushyphen.max`) have been generated by Kuiken (1990) to cover the exceptions by additional patterns and these add-on files are available on CTAN and other hosts, e.g., `ftp.cs.umb.edu`. *But*, after having added one of these files at the end of the `\patterns` command in `hyphen.tex`, in order to overcome huge exception lists that should be loaded with every document, one loses the compatibility between different installations and acts against Knuth's wishes.

The need to re-generate US English patterns

> `! TeX capacity exceeded, sorry`
> `  [exception dictionary=307.]`
> *DEK*

So, to follow Knuth's rules, every document should start with loading the exception file – for this, one has to increase TeX82's exception size (in words) from 307 to at least 607 (as is now usual in UNIXTeX, emTeX and other installations). However, this is barely sufficient for the current English exception file (remember one has to add words in all possible inflexions) but for flexive languages (such as Czech, where from one stem there are about 20 different suffices) it is unusable.

Maybe it is time to re-generate the patterns from a bigger (say, 200 000 entry) word-list once again from scratch?[4] Imagine the day when you will know that TeX will find 99.99 % of hyphens contained in your copy of Webster, so you will not have to go through a list of exceptions and a couple of dictionaries to check hyphenation points in your document! For backward compatibility one has to save every document together with the patterns and exceptions used anyway.[5]

Making Czech and Slovak hyphenation patterns with `PATGEN`

> *"A program should do one thing, and do it well."*
> *Ken Thompson*

The first Czech patterns were made in 1988 by Novák using `PATGEN` from a list of 170 000 word forms. Because of errors in his word-list, and only partially optimized `PATGEN` parameter settings, the patterns were good but not perfect.

The patterns weren't publicly available, so a second attempt was done by hand by Lhotka (1991) just as MacKay (1988) did for Turkish. Because of lots of exceptions to the 'rules', their usage was not quite comfortable either.

As Novák's list of words had been lately made public, we started compiling a bigger word-list from various sources using the old patterns for boot-strapping. We've learned a lot from the experience described by Rynning (1991) and Haralambous (1993b) and in a tutorial (Haralambous, 1994).

---

[4] Otherwise in 2050 there will have to be an extra issue of *TUGboat* devoted to the publication of exceptions to `hyphen.tex`.

[5] A search on `CTAN` via `quote site index` command shows 5 files of *different* lengths with the name `hyphen.tex`. (And Knuth and Liang's `hyphen.tex` can be found there under four different names – `hyphen.tex`, `ushyph1.tex`, `ushyphen.std`, `ushyphen.tex` – which leads to the total confusion!)

Petr Sojka and Pavel Ševeček

Czech hyphenation rules Czech hyphenation rules are described in (Zdeněk Hlavsa et al, 1993, pp. 56–57) and in a special book (Haller, 1956) where a list of exceptions was published. Briefly, we have syllable hyphenation with 'etymological' exceptions. Hyphenation is preferred between a prefix and the stem, and on the boundary of compound words. Things become complicated when:

1. The word evolved in such a way that although historically it was built from a prefix plus the stem of another word, today it is perceived as a new word stem. As an example may serve the word `ro-zu-mět` – "to understand" (syllable division) against `roz-u-mět` (`roz` is the prefix and `umět` means "to know").

2. There is no agreement on word hyphenation – e.g., the *current* rules for word `sestra` – "sister" allow one to hyphenate `se-stra`, `ses-tra` and `sest-ra`.

3. Word stem hyphenation points change when a suffix is added – e.g., `hrad` – "castle" can't be hyphenated, but with a suffix could – `hra-du`.

4. Compound words e.g. `tři-a-třiceti-letý` – "33 years old" are taken into account. Czech has a lot of compound words, but not to the extent that German has.

5. The hyphenation of a word depends on the semantics: `nar-val` and `na-rval`.

These rules make it hard to create patterns that describe all these exceptions and exceptions to exceptions. As we had handy a word-list with lists of allowable prefixes and suffixes, together with preliminary patterns to hyphenate word stems for bootstrapping, we decided to generate a hyphenated list of Czech words for `PATGEN`.

Stratified sampling

> "A large body of information can be comprehended reasonably well by studying more or less random portions of the data. The technical term for this approach is stratified sampling."
> (Knuth, 1991, p. 3)

Czech is a very flexive language; on average 20–30 inflexions can be derived from one word stem by changing the suffix added and one can multiply it almost twice, as negation can be created from many words (adjectives, verbs) by prefixing `ne`. Thus from a 170 000 stem word-list about 5 000 000 inflexions may be generated. Generating patterns from such a list would be very impractical. Because the suffixes are often the same or similar, we generated a word-list by means of the following rules:

1. We add only every 7th (actually 17th worked as well) derived word form from the full list to the `PATGEN` input list, with exceptions that:

2. every stem must be accompanied by at least one derived form, and

3. every derived form with overlapping prefixes has to be present in the `PATGEN` input list as well, and

4. only one word with prefixes `ne` (by which one can create negation to almost every word) and `nej` (by which one creates superlatives) is included, and

5. the hand-made list of exceptions from Haller (1956) (about 10 000 words) and other sources are always included.

With this procedure we have 372 562 Czech words to work with `PATGEN`. We used the same approach for Slovak. The results are in table 3.

Table 3: `PATGEN` statistics for the Czech and Slovak languages

| # of words | # of hyphenation points | | |
	Correct	Wrong	Missed
Czech			
372562	1019686 (98.26 %)	39 (0.01 %)	18086 (1.74 %)
Slovak			
333139	1025450 (98.53 %)	34 (0.01 %)	15273 (1.47 %)

Samples of `PATGEN` statistics are presented in tables 4, 5 and 6. These tables show that by twiddling with `PATGEN` parameters one may generate various versions of patterns. Usually the size of patterns and % of bad hyphenations are the minimization criteria, but maximization of % of good (found) hyphenations and other strategies might be chosen.

Compound words

> "Hints for hyphenation are most often needed at the word boundaries of compound words."
> (Saarinen, 1988, p. 191)

As an experiment we took our (rather huge) word-list of Czech words in which there was marked hyphenation only on prefix and compound word boundaries.

Table 4: Standard Czech hyphenation with Liang's parameters for English

level	length	param	% correct	% wrong	# patterns	size
1	2–3	1 2 20	96.95	14.97	+ 855	
2	3–4	2 1 8	94.33	0.47	+1706	
3	4–5	1 4 7	98.28	0.56	+1033	
4	5–6	3 2 1	98.22	0.01	+2028	32 kB

Table 5: Standard Czech hyphenation with improved (size optimized) strategy (cf. table 3)

level	length	param	% correct	% wrong	# patterns	size
1	1–3	1 2 20	97.41	23.23	+ 605	
2	2–4	2 1 8	85.98	0.31	+ 904	
3	3–5	1 4 7	98.40	0.78	+1267	
4	4–6	3 2 1	98.26	0.01	+1665	23 kB

Table 6: Standard Czech hyphenation with improved (% of correct optimized) strategy

level	length	param	% correct	% wrong	# patterns	size
1	1–3	1 5 1	95.43	6.84	+2261	
2	1–3	1 5 1	95.84	1.17	+1051	
3	2–5	1 3 1	99.69	1.24	+3255	
4	2–5	1 3 1	99.63	0.09	+1672	40 kB

Table 7: Czech hyphenation of composed words with Liang's parameters but allowing 1-length patterns in level 1

level	length	param	% correct	% wrong	# patterns	size
1	1–3	1 2 20	72.97	14.32	+ 300	
2	2–4	2 1 8	69.32	3.09	+ 450	
3	3–5	1 4 7	84.09	4.02	+ 870	
4	4–6	3 2 1	82.61	0.33	+2625	25 kB

Table 8: Czech hyphenation of composed words with slightly modified parameters(% of correct slightly optimized)

level	length	param	% correct	% wrong	# patterns	size
1	1–3	1 2 20	72.97	14.32	+ 300	
2	2–4	2 1 8	69.32	3.09	+ 450	
3	3–5	1 4 3	90.82	4.24	+3014	
4	4–6	3 2 1	89.07	0.36	+2770	40 kB

Table 9: Czech hyphenation of composed words with other parameters (% of correct optimized, but % of wrong and size increased)

level	length	param	% correct	% wrong	# patterns	size
1	1–3	1 5 1	64.35	5.34	+1415	
2	2–4	1 5 1	67.10	1.88	+1261	
3	3–5	1 3 1	97.94	5.39	+8239	
4	4–6	1 3 1	97.91	1.14	+2882	84 kB

Petr Sojka and Pavel Ševeček

The `PATGEN` program was able to produce hyphenation patterns for this list successfully. The number of patterns was rather large, but feasible (25–84 kB, depending on parameters). From a 380 698 item word-list the patterns found 307 470 of the hyphenation points[6] correctly, 5 040 points were hyphenated wrongly (exceptions), and 4 680 hyphenation points were missing.

To test the possibility of creating patterns for compound words in detail, we generated a word-list of more than 100 000 words with 101 687 hyphenation points marked. The list included both compound words and simple ones too.

The results of some of the runs are shown in tables 7, 8 and 9.

Some other numbers Just for fun we've tried patterns for different languages on our Czech `PATGEN` input word-list—see table 10. There are interesting speculations about these numbers—e.g., trying Slovak patterns on the Czech word-list, one finds more than 90 % of hyphenation points. On the contrary, probably because of non-syllabic principles and different rules for pronunciation, UK English rules are totally different — only 19 % of Czech words are hyphenated correctly by UK patterns. Surprisingly, Swedish, Finnish and Dutch (NE$_3$) patterns make fewer wrong hyphenations than the Czech old hyphenation patterns. The difference between Dutch patterns made by hand (NE$_3$) based on the syllabic principle) and those made by `PATGEN` (NE$_1$, NE$_2$) may by caused by the fact that general syllable hyphenation is relatively good for languages in which the hyphenation is based on syllabic principles. Having hyphenated word lists of different languages, it might be interesting to measure the 'syllabic principles of hyphenation' of different languages on an universal syllable hyphenation.

As hyphenation in most languages is based on syllabic principles, it is worth trying to create universal syllabic hyphenation and only learn the difference (exceptions) from this universal hyphenation. Let's try to summarize what we think should be done in the future.

---

[6] Some of these points might be wrong, as the database we used is only preliminary. Due to our experience with the standard hyphenation list, after correction of errors (wrongly marked hyphenation points, typos) `PATGEN` can generalize *substantially* better and the size of the list of patterns is reduced significantly.

Table 10: Patgen-like statistics for using various language patterns on Czech hyphenated word-list

Language	Correct	Wrong	Missed
CZ (Sev)	98.26 %	0.01 %	1.74 %
NE$_3$	57.38 %	4.11 %	42.62 %

* with transformed patterns — accented letters substituted by non-accented ones

Future

> "I hope T$_E$X82 will remain stable
> at least until I finish Volume 7
> of The Art of Computer Programming."
> (Knuth, 1989, p. 625)

Possible extensions in a successor to T$_E$X

> "Good typography therefore is a silent art;
> not its presence but rather
> its absence is noticeable"
> (Mittelbach and Rowley, 1992b)

It seems feasible to incorporate either S^{I}T$_E$X (Barth, Steiner, and Herbeck, 1993) changes or separate compound word hyphenation patterns in ε-T$_E$X.

These experiments, discussed above (in the section "Compound words") show that, even with the current T$_E$X, only doubling the patterns for a language with compounds might allow, e.g., switching between standard hyphenation in narrow columns and compound-word-only hyphenation in wide columns.

With a simple change in the program, one may achieve additional flexibility in hyphenation:

New registers `\leftcompoundhyphenmin` and `\rightcompoundhyphenmin` may be helpful for filtering unneeded hyphenation near compound word borders and `\compoundwordhyphenpenalty` might set a penalty (usually much lower than

`\hyphenpenalty`) for breaks on compound word boundaries. In this case `\compoundwordchar` character (i.e., the compound work mark in the DC fonts) could be *automatically* inserted there to prevent ligatures going over a compound word boundary.

Another minor addition might be added too, e.g., ε-TeX: in the old version of MLTeX there was implemented a flag `\dischyph` indicating whether or not to hyphenate words with discretionaries (i.e. embedded hyphens) or not. As an example may serve the citation (for Author-Prepared Books, 1993) in this paper, where we had to insert discretionaries by hand in the compound word "Author-Prepared" to achieve the limits on underfull boxes set by the editor. With setting `\dischyph=1` this wouldn't be necessary.

Pattern generalization Apart from `PATGEN` extensions according to character clustering, which are orthogonal, we are thinking of the following generalization. Currently, there are only 2 classes of inter-letter state: an odd or even number that carries information whether to hyphenate or not. The natural generalization would be to have n classes. Inter-letter numbers in patterns would code these classes in such a way that number m between letters will mean that this position belongs to the class number m (mod n) (when numbering classes from 0). The case $n = 2$ is the current situation, so `\pattern[2]` might mean the classical Liang patterns. Another class might be prefix boundary, compound word boundary or whatever else might possibly be useful for the hyphenation algorithm to be aware of in the word (discretionary being another possibility).

An application for English is straightforward too. Our approach will allow one to distingush "preferred" and "less recommended" classes of hyphenation points as published in Allen (1990).

In German, one may make other classes (and patterns), e.g. classes for different discretionary breaks.

Possible extensions in a successor to TeX

> "Please correct if you have a hyphenated word
> at the bottom of a right-hand page."
> *(for Author-Prepared Books, 1993)*

A possible direction was shown by Plaice (1993) and in Haralambous and Plaice (1994) and Plaice (1994). With suggested clustering of letters and enriched `PATGEN` (Liang and Breitenlohner, 1991) one could achieve context-dependent discretionaries and thus solve the `c-k` → `k-k`-like problems in German.

Taylor (1992, p. 249) mentions a possible definition of `\brokenpenalty` = `\ifrecto` 500`\else` 200`\fi`. If the output routine could communicate with the parameter-breaking algorithm, word breaks crossing page boundaries could be eliminated.

Conclusions

> *"Therefore it still is not the right moment*
> *to manufacture TeX on a chip."*
> *(Knuth, 1989, p. 641)*

In our survey we presented an overview on the topic of hyphenation in TeX and our results based on experience with Czech and Slovak. We conclude that the current possibilities of TeX are far from perfect and might be improved either in the scope of TeX82 (creation of better hyphenation patterns for various languages by `PATGEN`), ε-TeX (e.g. duplication of hyphenation mechanism for compound words), or Ω or $\mathcal{NTS}$ (special capabilities for context-dependent discretionaries).
